Verification of the FtCayuga Fault-Tolerant Microprocessor System

Volume 2: Formal Specification and Correctness Theorems

Mark Bickford and Mandayam Srivas

ORA Corporation
Ithaca, New York

Contract NAS1-18972
July 1991
Abstract

This is the second volume of a two-volume report that presents a formal specification and verification of a property of a quadruplicately redundant fault-tolerant microprocessor system design. This volume gives a complete listing of the formal specification of the system and the correctness theorems that were proved. The system performs the task of attaining interactive consistency among the processors using a special instruction on the processors. The design is based on an algorithm proposed by Pease, Shostak and Lamport. The microprocessor used in the system is called FtCayuga, which was designed by extending another formally verified microprocessor MiniCayuga. The property verified ensures that an execution of the special instruction by the processors correctly accomplishes interactive consistency, provided certain preconditions hold, using a computer-aided hardware design verification tool, Spectool, and the theorem prover, Clio, both of which were developed at ORA. A major contribution of the work is the demonstration of a significant fault-tolerant hardware design that is mechanically verified by a theorem prover.

Key Words: Fault-tolerance, hardware verification, mechanical theorem proving.

1 Introduction

NASA Langley Research Center has recently initiated a research effort to develop a validation methodology for life-critical digital (fly-by-wire) flight control systems. Such systems must meet stringent reliability requirements. The systems are expected to have a probability of failure as low as $10^{-9}$ for a 10 hour mission. Hence, as has been well-argued in [6], the design and validation methods employed for such systems must meet high standards. The designs must use fault-tolerant strategies to enable the continued operation of the system in the presence of component failures. The validation methods must ensure that there are no design errors in the system.

The process of formal verification is capable of showing that a system design satisfies a specified property for all inputs and initial conditions of the design. Hence it is a promising candidate for consideration as a validation technology for flight control systems. Digital control systems are implemented using a combination of hardware and software components. Hence, a formal verification technology for flight control systems must be applicable to both software and hardware designs. This work is concerned with the formal verification of a hardware design.

This report presents the formal verification of a hardware system for a task that is an important component of a fault-tolerant computer architecture for flight control systems. The hardware system implements an algorithm for attaining interactive consistency (byzantine agreement) [2] among four microprocessors as a special instruction on the processors. The property verified ensures that an execution of the special instruction by the processors correctly accomplishes interactive consistency, provided certain preconditions hold. An assumption is made that the processors execute synchronously. For verification, we used a computer-aided hardware design verification tool, Spectool [3], and the theorem prover, Clio [1], both of which were developed at ORA. The microprocessor used in the system is called FtCayuga, which we designed by extending the the formally verified microprocessor MiniCayuga [4].

A major contribution of the work is the demonstration of a significant fault-tolerant hardware design that is mechanically verified by a theorem prover. The work illustrates the advantage of using hierarchy and abstraction in system design specification to manage the complexity of formal verification. The work demonstrates the value of a special-purpose tool that tailors the use of a theorem prover to a hardware domain in order to reduce the effort
required for formal verification.

This is the second volume of a two-volume report. The first volume [5] contains an overview of the work and an informal description of the specification and the proof of correctness. This volume contains the entire specification of the system and the definitions of all the correctness theorems and lemmas we proved. This volume is intended as a supplement to Volume 1, and, hence, the presentation in this volume assumes that you have read Volume 1.

The next section describes the general structure of a specification generated by Spec- tool, which also appeared as appendix section A in Volume 1. We repeat this description here for easy reference. The description is useful in understanding the design specifications of the main blocks—\texttt{IcNet}, \texttt{Voter}, and \texttt{FtCayuga}—of our system. The rest of the material in this volume is organized as follows.

1. The \texttt{Voter Specification} section contains the design and abstract specifications of the \texttt{Voter}.

2. The \texttt{FtCayuga Specification} section contains the design and abstract specifications of \texttt{FtCayuga}.

3. The \texttt{IcNet Specification} section contains the design and abstract specifications of \texttt{IcNet}.

4. The \texttt{Common Theory} section contains definitions of the data types and primitive functions on the data types that are used in the previous specifications. Some of these types are unimplemented abstract types which are specified by axiomatizing the operations on them.

5. The \texttt{Main Lemmas} section contains the definitions of the main theorem and the main lemmas with the help of which the main theorem was proved. The bridge theorems that connect the two levels of descriptions of \texttt{IcNet} and \texttt{Voter} appear as part of the abstraction specifications of the respective components. Since we did not prove the bridge theorems for \texttt{FtCayuga}, we have not included them here.

6. The \texttt{General Lemmas} section contains the set of basic lemmas that were used in proving one or more of the lemmas in the \texttt{Main Lemmas} section.
2 General Structure of a Specification Generated by Spectool

A design specification generated by Spectool consists of the parts described in the following sections.

2.1 Structural Specification Part

This part specifies the data path architecture. It defines a set of types to model the data path state and a set of functions to specify the connections between the data path components. Spectool generates this part in a generic fashion from the following structural information about the data path provided by the user:

1. the names of components and component classes,
2. the names of the actions defined on components,
3. the types that model the internal states of components,
4. the types of the external inputs to the circuit, and
5. the graphical connections between components.

To give the reader an idea of this part of a design specification, a fragment of the structural specification part of the voter circuit is shown below.

```
|| Generic part of the data path state definition
|| type SYSTEM_STATE = COMP->LOCAL_STATE
|| type INPUT_STREAM = NAT->EXTSTATE
|| type CHANGE = <<COMP,NAT,LOCAL_STATE>>
|| type STATE = <<SYSTEM_STATE, [CHANGE], INPUT_STREAM>>

|| A type for every component class. The type defines the names of
|| all the components used in the data path that belong to the class.
|| majority ::= MAJ1 | MAJ2 | MAJ3
|| bytereg ::= PR1 | PR2 | PR3 | R12 | R13 | R23 | R31 | R32
```
bitlatch ::= VS | ST

|| A labeled union type of all the component class types
COMP ::= Controller | C_majority !majority | C_mux4 !mux4
   | C_bytereg !bytereg | C_bitlatch !bitlatch

|| A labeled union type of all local states of components
LOCAL_STATE ::= S_Controller !CONTROLSTATE
   | S_majority !majority_localstate
   | S_mux4 !mux4_localstate
   | S_bytereg !bytereg_localstate
   | S_bitlatch !bitlatch_localstate

ACTION ::= A_majority !majority_ACT
   | A_mux4 !mux4_ACT
   | A_bytereg !bytereg_ACT
   | A_bitlatch !bitlatch_ACT

|| The following specifies the input connections to the component MAJ2
majorityinput s (C_majority MAJ2) =
   <<getbyteregout0 (current s (C_bytereg R32)),
    getbyteregout0 (current s (C_bytereg R12)),
    getbyteregout0 (current s (C_bytereg PR2))>>

The type STATE defines the data path state as a tuple: <<SYSTEM_STATE, [CHANGE],
INPUT_STREAM>>. SYSTEM_STATE maps every component (an element of type COMP) in
the data path to its LOCAL_STATE. [CHANGE] is the list of pending actions on the data path
components. This list is maintained to simulate the effect of delays on actions. The list
contains an update record for each of the actions that has been triggered by the controller
on components, but is yet to be completed. The first two fields of STATE define a snapshot
in time of the data path state. The state of a component is given by SYSTEM_STATE unless
an action is pending on the component, in which case the state is bottom.

The third field of the tuple, INPUT_STREAM, specifies the values of the external inputs
to the circuit as function of time. INPUT_STREAM is a function type from time (NAT) to
EXTSTATE, where EXTSTATE is a type that combines all the external inputs into a tuple.
The type **LOCAL_STATE** is a labeled union of the *local states* of all the components of the data path (and the controller). The local state type of a component is a tuple of its internal state and (a tuple of) its outputs. The definition of the local state type of a component appears as part of the component class specification.

The set of components in a data path is organized so that every component is an instance of a component class. The type **COMP** groups together the names of all the components in a data path. It is defined as a labeled union of all the component class types, where a component class type is an enumerated type of the names of all the components belonging to the corresponding class.

Similarly, the type **ACTION** groups together the names of the action types of the component classes, where the action type of a component class is an enumerated type of the names of all the actions defined for the class. The definition of the action type of a component appears as part of the component class specification.

Connections between data path components are specified by defining, for every component, a function that determines the inputs to the component in a given data path state.

### 2.2 Component Classes Specification Part

Every component in the data path is an instance of a component class. The components belonging to the same class share several attributes. This part specifies the shared attributes of a class for every class used in a design. A component class specification defines the type that denotes the internal state of a components of the class, the types of the outputs, a type denoting the names of the actions on the components, and the effects of the actions on the components. For every action, it defines three functions: “state” and “output” functions return, respectively, the new state and the new outputs of a component after an action is performed; and the “delay” function gives the delay associated with the action. For illustration, a part of the specification of the majority component class used in the voter circuit is given below.

```plaintext
// The component class majority.
// Local state of majority: <<<internal state type, <<output types>>>>
type majority_localstate = <<<data, BOOL>,<<(byte),(BOOL)>>>
```
Type denoting the actions on the components of the class

```plaintext
majority_ACT ::= select3 !majority | select2 !majority | select0 !majority | select1 !majority | comp !majority
```

```plaintext
majoritydelay (select3 c) = #0
majoritycomp (select3 c) = C_majority c
majorityout (select3 c) s <<in1,in2,in3>> = <<get_byte 3 (dataof s), bitof s>>
majoritystate (select3 c) s <<in1,in2,in3>> = s

majoritydelay (select2 c) = #0
majoritycomp (select2 c) = C_majority c
majorityout (select2 c) s <<in1,in2,in3>> = <<get_byte 2 (dataof s), bitof s>>
majoritystate (select2 c) s <<in1,in2,in3>> = s
```

**2.3 Controller Specification Part**

A controller is specified by means of two functions `nextstate` and `scheduler`. The `nextstate` function gives the next controller state as a function of the current state and controller inputs. The `nextstate` function is used at the end of each cycle to advance the controller state. The function `scheduler` returns a list of actions as a function of the controller state, controller inputs, and the phase. For illustration, a part of the specification of the controller for the voter circuit is shown below.

```plaintext
CONTROLSTATE ::= LDP1 | LDP2 | XNG11 | XNG12 | XNG21 | XNG22 | XNG31 | XNG32 | CMPP | OUT1 | OUT2

nextstate LDP1 in = (~(startedof in))->(LDP1);(LDP2)
nextstate LDP2 in = XNG11

scheduler XNG11 <<vstart, started>> 0 = (selprvtbyte0)
```
selprvt1byte0 = [Abytereg(read0 PRI), A_mux4(choose3 MUX)]

scheduler XNG12 <<vstart, started>> 0 = (selprvt1byte2)

selprvt1byte2 = [Abytereg(read2 PR1), A_mux4(choose3 MUX)]

...  
|| Some of the details specific to the voter design
|| There are 4 clock phases per cycle.
num_phases = 4

2.4 Composite Behavior Specification Part

This part defines a set of functions that derive the composite behavior of a design using the information expressed in the rest of the specification. This part formalizes in Caliban the operational model of the behavior of a finite state controller system. This part is identical for every circuit since Spectool generates it in a completely generic fashion. The higher-order function definition capability of Caliban is a primary reason why it is possible to express this part in a generic fashion. A top level fragment of this part of the specification is shown below.

Execute s = do_phases 0 s

Output s = generate_output 0 s

do_phases n s = update_state s , n = num_phases
do_phases (n+1) (do_phase n s)

do_phase n <<s,p,in>> =
  advance_inputstream (do_actions (current_schedule s2 n) s2)
  where s2 = update_state <<s,p,in>>

The two main functions defined in this part are Execute and Output. Execute advances the state of the system across a single cycle. Output returns the (tuple of) external outputs produced by the circuit over the next cycle. Output actually returns a list outputs, one for every phase in a cycle. The two functions are defined hierarchically in terms of several other functions, some of which are described below.
To simulate the effect of delays on component actions, the specification maintains a list of records of pending updates that have been triggered by the controller, but are yet to take effect on the circuit state. The update record for an action contains the component on which the update is pending, a time-out counter that is initialized to the delay of the action and decremented after every phase, and the result of the update. The function `update.state` causes the result of all the update records on the list that have timed out to take effect on the circuit state. The function also decrements the time-out counter of the update records that have not yet timed-out by one unit of time. The purposes of the rest of the functions should be apparent from the names of the functions. They are summarized below.

- The function `do.phases` updates the state for all the phases in a cycle.
- The function `do.phase` updates the state for a single phase. It causes (using `update.state`) the pending updates that have timed out to take effect; gets the `current.schedule` from the controller, makes new update records (using `do.actions`) for all the actions in the schedule, and then advances the input stream by a time unit.

3 Voter Specification

3.1 Abstract Specification

get_maj_val 3 <<<<b0,b1>>,<<c0,c1>>,<<d0,d1>>>= d0

low_half (DATUM (Word byte3 byte2 byte1 byte0)) = <<byte0, byte1>>
high_half (DATUM (Word byte3 byte2 byte1 byte0)) = <<byte2, byte3>>
crossout <<cstate,array,maj,go>>
  = xng_out cstate array || depends only on cstate and array

xng_out cs array
  = sendlow 1 array, (cs = XNG11)
  sendhigh 1 array, (cs = XNG12)
  sendlow 2 array, (cs = XNG21)
  sendhigh 2 array, (cs = XNG22)
  sendlow 3 array, (cs = XNG31)
  sendhigh 3 array, (cs = XNG32)
  dont_care || don't care, otherwise

sendlow n array = <<get_byte 0 (array 1 n), get_byte 1 (array 1 n)>>
sendhigh n array = <<get_byte 2 (array 1 n), get_byte 3 (array 1 n)>>
statusout <<cstate,array,maj, go>> = getstatus maj, (cstate = CMPP)
dont_care
getstatus <<<maj11,maj12>>> = <<<maj21,maj22,<<maj31,maj32>>> = <<<maj12,maj22,maj32,<<maj12,maj22,maj32>>> =
sndngout <<cstate,array,maj,go>> = <<<True,True>, (cstate = OUT1)
<<True,True>, (cstate = OUT2)
<<False,False>>
freeout <<cstate,array,maj,go>> = <<<True,True>, (cstate = LDP1)
<<False,False>>

| Now the tuple <maj_out 1 s, maj_out 2 s, ..., freeout s> will be a tuple |
| of lists of length two. The output function at the lower level |
| gives a list of tuples of length two. To compare the two levels, |
| we must "transpose" one of the representations. |

transpose [ <<a0,b0,c0,d0,e0,f0,g0>>, <<a1,b1,c1,d1,e1,f1,g1>> ] =
<< <<a0,a1>>,<<b0,b1>>,<<c0,c1>>,<<d0,d1>>,<<e0,e1>>,<<f0,f1>>,<<g0,g1>> >>
VoterOut s = <maj_out 1 s,maj_out 2 s,maj_out 3 s,statusout s, |
| crossout s,sndngout s,freeout s>>
VoterOut_Lemma := 'VoterOut (VoterABS s)'
<= 'transpose (Output s)', Proper_state 's'

| Now we will write another description of the voter, similar to the one |
| above, but with the inputs and outputs grouped differently and with |
| the input stream separated from the state. This description is used |
| when the voter is thought of as a component in a larger system. |

type ARRAY = NUM->NUM->data

type MAJSTATE = <<data,BODL>>

type MAJROW = <<MAJSTATE,MAJSTATE,MAJSTATE>>

type VOTERSTATE = <<CONTROLSTATE,ARRAY,MAJROW,BOOL>>

| The input tuple used above has the form <<pvt1,pvt2,pvt3,v1,v2,v3,b>>, |
| and each cycle consumes four such tuples from the input stream. |
| The new description of the voter is as a component having |
| four inputs from_proc = <go,pvt1,pvt2,pvt3>, and v1, v2, and v3, |
| each of which is a four tuple (representing the values on the input wires |
| in each of the four phases). |

serial_from_proc <<<<<go0,go1,go2,go3>>,<<pvt10,pvt11,pvt12,pvt13>>, |
<<pvt20,pvt21,pvt22,pvt23>>,<<pvt30,pvt31,pvt32,pvt33>>>,v1,v2,v3>> =
[<<pvt10,pvt20,pvt30,go0>>, <<pvt11,pvt21,pvt31,go1>>, <<pvt12,pvt22,pvt32,go2>>, <<pvt12,pvt22,pvt32,go2>>]

serial_from_voter <<pr,<<v10,v11,v12,v13>>,<<v20,v21,v22,v23>>, |
<<v30,v31,v32,v33>>>,v1,v2,v3>> =

| So, in the new description, the voter has a state s :: VOTERSTATE |
| and it gets an input in = <from_proc, from_v1, from_v2, from_v3>>.

11
We can define its new state by using the function VoterStep defined above.

\[
\text{voterstep } s \text{ in } = \text{VoterStep } s (\text{serial\_from\_proc in})(\text{serial\_from\_voter in})
\]

The voter-component will have four output ports: to\_proc, cross1, cross2, and cross3. The "cross" outputs will all be the same:

\[
\text{cross\_out } <<\text{cs}, \text{array}, \text{maj}, \text{b}}>> = \text{pad } (\text{xng\_out cs array})
\]

\[
\text{pad } <<a, b>> = <<a, a, b, b>>
\]

The output "to\_proc" contains all the other output of the voter:

\[
\text{to\_proc } s = \text{drop\_cross } (\text{VoterOut } s)
\]

\[
\text{drop\_cross } <<\text{m1,m2,m3,status,cross,sndng,free}}>> =
<<\text{m1,m2,m3,status,sndng,free}}>>
\]

good\_array a =
\[
\begin{align*}
& \text{(good } (a 1 1)) & \& \text{(good } (a 1 2)) & \& \text{(good } (a 1 3)) \\
& \& \text{(good } (a 2 1)) & \& \text{(good } (a 2 2)) & \& \text{(good } (a 2 3)) \\
& \& \text{(good } (a 3 1)) & \& \text{(good } (a 3 2)) & \& \text{(good } (a 3 3))
\end{align*}
\]

good\_maj\_row <<\text{a,b,c}}>> = \text{good\_maj a } & \& \text{(good\_maj b)} & \& \text{(good\_maj c)}

good\_maj <<a,b}} = \text{good a } & \& \text{!b}

Here are some functions we need to specify the next level of abstraction.

\[
\text{control } <<\text{cs, array, maj, go}}>> = \text{cs}
\]

\[
\text{arrayof } <<\text{cs, array, maj, go}}>> = \text{array}
\]

\[
\text{maj\_of } <<\text{cs, array, maj, go}}>> = \text{maj}
\]

\[
\text{go\_of } <<\text{cs, array, maj, go}}>> = \text{go}
\]

\[
\text{row\_of } <<\text{cs, array, maj, go}}>> = <<\text{array 1 1, array 1 2, array 1 3}}>>
\]

Now we'll define a predicate that says how well defined the inputs to the voter need to be in order to result in a Proper\_voterstate.

\[
\text{good\_voter\_in } \text{cs in } = \text{!!(serial\_from\_voter in), xng\_cycle cs}
\]

\[
\text{!!(serial\_from\_proc in)}
\]

\[
\text{xng\_cycle XNG11 = True}
\]

\[
\text{xng\_cycle XNG12 = True}
\]

\[
\text{xng\_cycle XNG21 = True}
\]

\[
\text{xng\_cycle XNG22 = True}
\]

\[
\text{xng\_cycle XNG31 = True}
\]

\[
\text{xng\_cycle XNG32 = True}
\]

\[
\text{xng\_cycle cs = False}
\]

\[
\text{Proper\_voterstate\_lemma :=}
\]

\[
(\text{Proper\_voterstate } s' & \text{ 'good\_voter\_in (control s) in'='True')} => \text{Proper\_voterstate } 'voterstep s in'
\]

12
When the voter state is not LDP1 the the nextstate is a function of the current state only. We need to export this function:

\[
\text{next_voterstate } s = \text{nextstate } s \text{ bottom}
\]

4.3 Common Part

This section contains the definitions of the types and functions that are used in the abstract as well as the design specifications of FtCayuga.

FROM CommonTheorySec IMPORT data, byte, addr, regaddr, sregaddr, opcode, opclass,
The abstract state consists of the memory state, the NXPC, the state of
the registers, the current instruction, and an input stream.

```
| The abstract state consists of the memory state, the NXPC, the state of |
| the registers, the current instruction, and an input stream. |
| type ABS_EXTSTATE = <<BOOL, [byte], [byte], [byte], [byte]>> |
| type ABS_STATE = <<addr->data, data, regaddr->data, data, |
| sregaddr->data,[EXTSTATE]>> |
|
mem <<m, p, r, i, sr,in>> = m |
xpc <<m, p, r, i, sr,in>> = p |
reg <<m, p, r, i, sr,in>> = r |
instrn <<m, p, r, i, sr,in>> = i |
ins <<m, p, r, i, sr,in>> = in |
sreg <<m, p, r, i, sr,in>> = sr |
```

```
Step s = <<newmem s, newxpc s , newreg s, newinstr s , newsreg s,newins s>>
```

```
newmem s = store_effect s , current_opclass s = SCLASS |
mem s |
newreg s = alu_effect s, current_opclass s = ACLASS |
load_effect s, current_opclass s = LCLASS |
reg s |
```

```
The new current instruction is usually fetched as follows: |
prefetch s = mem s (data_to_addr(nxpc s)) |
```

```
But when there is an interrupt the instruction isn't prefetched. |
Right now, there's only one interrupt, so the handler is at whatever |
is in memory at addr_0. |
handler s = newmem s addr_0 |
handler_fetch s = newmem s (data_to_addr(handler s)) |
```

```
newinstr s = handler_fetch s , interrupt s |
prefetch s |
```

```
The new next pc. |
newxpc s = inc_data(handler s), interrupt s |
jump_effect s, current_opclass s = JCLASS |
inc_data(nxpc s) |
```

```
We must define at the abstract level the function that tells us |
how many inputs to take from the input stream. |
load_or_store x = (x=LCLASS)xor(x=SCLASS) |
interruptof <<int,v1,v2,v3,st>> = int |
interrupt s { load_or_store (opcodeof (opcodeof (instrn s)))) |
= (interruptof(hd (ins s))interruptof(hd(tl (ins s)))) |
interrupt s = interruptof(hd (ins s)) |
```

```
um_cycles s { load_or_store (opcodeof (opcodeof (instrn s)))) |
= (interrupt s) ->#4;#2 |
um_cycles s = (interrupt s) ->#3;#1 |
```

46
newins s = remove (num_cycles s) (ins s)
remove Zero l = l
remove (Succ n) l = remove n (tl l)

|| The current instruction is decoded:
current_op s = opcodeof (instrn s)
current_opclass s = opclassof (current_op s)
current_ind s = indirect (instrn s)
current Src1 s = srclof (instrn s)
current Src2 s = src2of (instrn s)
current_dst s = data_to_regaddr (dstof (instrn s))
current_sdst s = data_to_sregaddr (dstof (instrn s))

|| Operand1 is the contents of register src1.
current_operand1 s = reg s (current_src1 s)

|| If the addressing mode is indirect then operand2 is the contents of
|| the register src2, otherwise it's src2 itself.
current_operand2 s = reg s (data_to_regaddr (current_src2 s)), current_ind s
current_src2 s

|| The alu operation is usually add:
current_aluop s = which_op (current_op s)
which_op CNE = cne_data
which_op x = add_data

|| The current result is computed by applying the current alu operation
|| to the current operands, unless the opcode is MOVE, in which case
|| it's the contents of special-register src1.
current_result s {current_op s = MOVE} =
sreg s (regaddr_to_sregaddr(current_src1 s))
current_result s = current_aluop s (current_operand1 s) (current_operand2 s)
alu_effect s = update (reg s) (current_dst s) (current_result s)

Some generic functions we need.

Iterate Zero f x = x
Iterate (Succ n) f x = Iterate n f (f x)

select Zero (a:x) = a
select (Succ n) (a:x) = select n x

The successor relation on the indices.

suc ONE = TWO
suc TWO = THREE
suc THREE = FOUR
suc FOUR = ONE

suc2 = suc.succ
suc3 = suc2.succ

Fault modelling

Everything is defined in terms of the parameter "faulty" which is a
predicate on the type INDEX which tells us which fault regions are faulty.
The possible faults are listed in the following enumerated type:

FAULT ::= Region !INDEX | NO_FAULT

To model the fact that we are assuming at most one fault, we can suppose
that there is a constant, "the_fault" of type FAULT, and then define the
predicate "faulty" in terms of that constant.

the_fault ::= FAULT
AXIOM '!the_fault'='True'
faulty index = (the_fault = (Region index))

This abstraction function lets us view the state of the ic-net
as a function from indicies to FTCayuga states, a function from indicies to voter states, and an input stream.

We wouldn't need this step if the spectool supported indexed components.

\[ \text{IcNetABS} \ = \ \langle \langle \text{FTCStates} \ s, \ \text{VoterStates} \ s, \ \text{inlist}_\text{from} \ s \rangle \rangle \]

\[
\begin{align*}
\text{FTCStates} \ s \ \text{ONE} & = \ \text{get\_FTC1\_state} \ s \\
\text{FTCStates} \ s \ \text{TWO} & = \ \text{get\_FTC2\_state} \ s \\
\text{FTCStates} \ s \ \text{THREE} & = \ \text{get\_FTC3\_state} \ s \\
\text{FTCStates} \ s \ \text{FOUR} & = \ \text{get\_FTC4\_state} \ s \\
\end{align*}
\]

\[
\begin{align*}
\text{VoterStates} \ s \ \text{ONE} & = \ \text{get\_V1\_state} \ s \\
\text{VoterStates} \ s \ \text{TWO} & = \ \text{get\_V2\_state} \ s \\
\text{VoterStates} \ s \ \text{THREE} & = \ \text{get\_V3\_state} \ s \\
\text{VoterStates} \ s \ \text{FOUR} & = \ \text{get\_V4\_state} \ s \\
\end{align*}
\]

The abstract state change (behavior) of the voter-net.

What happens at each index depends on whether that index is faulty.

\[
\text{IcNetStep} \ \langle \langle \text{ftc, vtr, int:rest} \rangle \rangle \ = \ \langle \langle \text{newftc, newvtr, rest} \rangle \rangle \]

where

\[
\begin{align*}
\text{newftc} \ \text{index} & = \ \text{fault\_ftc\_step} \ \text{index} \ \text{ftc} \ (\text{ftcinput} \ \text{index}) \\
\text{newvtr} \ \text{index} & = \ \text{fault\_vtr\_step} \ \text{index} \ \text{vtr} \ (\text{vtrinput} \ \text{index}) \\
\text{ftcinput} \ \text{index} & = \ \text{make\_ftc\_in} \ (\text{select\_int} \ \text{index} \ \text{int}) \\
\text{vtrinput} \ \text{index} & = \ \text{Voterinput} \ \text{index} \ \text{ftc} \ \text{vtr} \\
\end{align*}
\]

\[
\begin{align*}
\text{fault\_ftc\_step} \ \text{index} \ \text{s in} & = \\
\text{FtCayugaStep} \ (\text{s index}) \ \text{in} , \ \neg \text{(faulty index)} \\
\text{byzCayugaStep} \ (\text{s index}) \ \text{in} \\
\text{fault\_vtr\_step} \ \text{index} \ \text{s} & = \ \text{voterstep} \ (\text{s index}) , \ \neg \text{(faulty index)} \\
\text{byzstep} \ (\text{s index}) \\
\end{align*}
\]

\[
\begin{align*}
\text{select\_int} \ \text{ONE} \ \langle \langle a, b, c, d \rangle \rangle & = a \\
\text{select\_int} \ \text{TWO} \ \langle \langle a, b, c, d \rangle \rangle & = b \\
\text{select\_int} \ \text{THREE} \ \langle \langle a, b, c, d \rangle \rangle & = c \\
\text{select\_int} \ \text{FOUR} \ \langle \langle a, b, c, d \rangle \rangle & = d \\
\text{fault\_to\_proc} \ \text{index} \ \text{ftc} \ \text{vtr} & = \\
\text{to\_proc} \ (\text{vtr index}) , \ \neg \text{(faulty index)} \\
\text{byz\_to\_proc} \ (\text{vtr index}) \\
\end{align*}
\]

\[
\begin{align*}
\text{Voterinput} \ \text{index} \ \text{ftc} \ \text{vtr} & = \\
\langle \text{fault\_from\_proc} \ \text{index} \ \text{ftc}, \\
\text{fault\_cross} \ \text{THREE} \ (\text{succ3 index}) \ \text{vtr}, \\
\text{fault\_cross} \ \text{TWO} \ (\text{succ2 index}) \ \text{vtr}, \\
\text{fault\_cross} \ \text{ONE} \ (\text{succ index}) \ \text{vtr} \rangle \\
\end{align*}
\]

The function "fault\_from\_proc" gives the input tuple of values coming from the processors to the voter whose index is "index".

\[
\begin{align*}
\text{fault\_from\_proc} \ \text{index} \ \text{ftc} & = \\
\langle \text{fault\_vstart} \ \text{index} \ \text{ftc}, \\
\text{fault\_prvt} \ (\text{whichprvt index} \ (\text{succ index})) \ (\text{succ index}) \ \text{ftc}, \\
\text{fault\_prvt} \ (\text{whichprvt index} \ (\text{succ2 index})) \ (\text{succ2 index}) \ \text{ftc}, \\
\text{fault\_prvt} \ (\text{whichprvt index} \ (\text{succ3 index})) \ (\text{succ3 index}) \ \text{ftc} \rangle \\
\end{align*}
\]

The expression "whichprvt i j" tells us which replica of the private value of processor j is connected to voter i. This is only used when processor j is faulty, and tells us which of byzpvt1, byzpvt2, and byzpvt3 was used.

\[
\begin{align*}
\text{whichprvt} \ \text{ONE} \ i & = 1 \\
\text{whichprvt} \ \text{TWO} \ \text{ONE} & = 1 \\
\text{whichprvt} \ \text{TWO} \ i & = 2 \\
\text{whichprvt} \ \text{THREE} \ \text{FOUR} & = 3 \\
\end{align*}
\]
whichprvt THREE i = 2
whichprvt FOUR i = 3

fault_vstart i ftc = vstartout (ftc i), (faulty i)
byzgo (ftc i)

fault_prvt i1 i2 s = prvtout (s i2), (faulty i2)
byz_pvt i1 (s i2)

fault_cross i1 i2 s = cross_out (s i2), (faulty i2)
byz_cross i1 (s i2)

byz_cross ONE = byz_cross1
byz_cross TWO = byz_cross2
byz_cross THREE = byz_cross3

byz_pvt 1 = byz_pvt1
byz_pvt 2 = byz_pvt2
byz_pvt 3 = byz_pvt3

IcNetStepLemma :=

"IcNetABS (Execute s)"="IcNetStep (IcNetABS s)", Proper_state 's"

|| What we have done with this abstraction step is to organize the
|| state of the ic-net as a function on indicies,
|| and to hide the cross connections.

|************* Here is the translation of the Proper_state predicate for the ic-net |
| to a predicate on abstract ic-net. |
| Proper_inlist 'i' := 'is_proper_ext (select n l)'='True', '!n'='True' |

7 The Main Lemmas Proved

MainTheorem defines the main correctness property that we proved. It expresses the 12-cycle interactive consistency property for the entire system, which was described in detail in sections 5.2 and 9.1 of Volume 1. In the following, we describe some of the main lemmas that we proved in constructing a proof of MainTheorem.

MainTheorem states the interactive consistency property for the actual value (defined by the function actualPVT) that the processor sends to the voter. Since the processor sends the value to the voter over two cycles, we define one half of this value based on the contents of the special register PVT in the cycle in which ICOP is executed and the other half based on the contents of PVT in the following cycle. To ensure that the IC computation is performed on a consistent value of PVT, the programmer must make sure that the content of PVT will not change before the processor sends it to the voter. One way a programmer can ensure this is by not having a SADD instruction, which is the only instruction that can change the special register PVT, immediately following ICOP. AnotherMainTheorem formally states this condition. We have not proved this theorem, which should follow from the MainTheorem.

To decompose the proof of MainTheorem into smaller proofs, we divided the 12-cycle IC computation into a sequence of six stages of smaller duration. For each of these stages, we proved a stage lemma that defines the expected behavior for that stage. The different stages we used and their corresponding lemmas are enumerated below.
1. **Load stage** represents the first three cycles of IC computation in which the contents of the private register is moved from the processor to the voter. The lemma corresponding to this stage is *Load_correct_lemma*.

2. **Exchange stage** represents the next six cycles of the computation in which the voters exchange values between each other. This stage is further divided into a sequence of three 2-cycle computations, with one lemma for each of them: *Xng1_correct_lemma*, *Xng2_correct_lemma* and *Xng3_correct_lemma*.

3. **Compute stage** represents the single cycle in which majority computation is performed. The lemma corresponding to this stage is *Compute_correct_lemma*.

4. **Output stage** represents the last two cycle of the computation in which the results are written into the processor. The lemma corresponding to this stage is *Output_correct_lemma*.

We "chained" the stage lemmas together, in order, to prove the *MainTheorem*. We proved another set of lemmas, called *connect* lemmas, to assist us in the chaining process. That is, we used the connect lemmas to prove that the antecedent of a stage lemma implies the consequent of a succeeding stage lemma in the chain. The list given below shows the order in which we used the lemmas for proving the *MainTheorem*. In the following, CL is an abbreviation for "*Connect_lemma*,” and → is used to indicate the chronological order in which two lemmas are proved when the lemmas appear within the same item in the list.

1. *Load_correct_lemma*
2. CL_1.4 → (CL_1.5, CL_1.3) → (CL_1.1, CL_1.2)
3. *Xng1_correct_lemma*
4. (CL_1.1, CL_1.2) → CL_3
5. *Xng2_correct_lemma*
6. (CL_1.1, CL_1.2) → CL_4
7. *Xng_correct_lemma*
8. (CL_1.1, CL_1.2) → CL_5
9. *Compute_correct_lemma*. 

63
Now we specify the multi-cycle behavior of the ic net.
We only expect it to perform correctly under certain assumptions.
First, at the beginning of the multi-cycle computation, all the
non-faulty voters should be syncronized in their LDP1 state,
and be waiting for the go-signal.
And all the non-faulty processors should about to give the go-signal.
And all the non-faulty processors should have their bytecounter at BYTE1.
Using the following predicates, we can assert this condition
on the voternet state, s, as: Sync 'LDPI' 's' & All_go 's'

Sync 'cs' '<<ftc, vtr, inlist>>' :=
(faulty ONE'='False' => 'control (vtr ONE)='cs')
& ('faulty TWO'='False' => 'control (vtr TWO)='cs')
& ('faulty THREE'='False' => 'control (vtr THREE)='cs')
& ('faulty FOUR'='False' => 'control (vtr FOUR)='cs')

vtr <<f,v,in>> = v
ftc <<f,v,in>> = f
inlist <<f,v,in>> = in
GO = <<True,True,True,True>>
go_signal <<ftc,vtr,int:rest>> index = vstartout (ftc index)

All_go 's' :=
(faulty ONE'='False' => ('go_of (vtr s ONE)='False'
& 'go_signal s ONE='GO' & 'bytecount (ftc s ONE)='BYTE1'))
& ('faulty TWO'='False' =>
('go_of (vtr s TWO)='False'
& 'go_signal s TWO='GO' & 'bytecount (ftc s TWO)='BYTE1'))
& ('faulty THREE'='False' =>
('go_of (vtr s THREE)='False'
& 'go_signal s THREE='GO' & 'bytecount (ftc s THREE)='BYTE1'))
& ('faulty FOUR'='False' =>
('go_of (vtr s FOUR)='False'
& 'go_signal s FOUR='GO' & 'bytecount (ftc s FOUR)='BYTE1'))

Bytecount_sync 'b' 's' :=
(faulty ONE'='False' => 'bytecount (ftc s ONE)='b')
& ('faulty TWO'='False' => 'bytecount (ftc s TWO)='b')
& ('faulty THREE'='False' => 'bytecount (ftc s THREE)='b')
& ('faulty FOUR'='False' => 'bytecount (ftc s FOUR)='b')

II So, the preconditions to the main correctness theorem are:

Preconditions 's' :=
Proper_icnet 's' & Sync 'LDPI' 's' & All_go 's'

Some intermediate results.
Specification of the load cycles.
This function defines the actual private value used by ICOP
actualPVT s index =
half_and_half (newPVT2 (ftc s index) (first_interrupt s index))
 half_and_half (newPVT (ftc s index))

half_and_half hi lo = DATUM (Word (getbyte BYTE3 hi) (getbyte BYTE2 hi)
first_interrupt <<ftc,vtr,inlist>> index = select_int index (hd inlist)

load_correct 'before' 'after' 'index' :=

 => 'arrayof (vtr after index) 1 1'='actualPVT before (succ index)')
& ('faulty (succ2 index)='False'
 => 'arrayof (vtr after index) 1 2'='actualPVT before (succ2 index)')
& ('faulty (succ3 index)='False'
 => 'arrayof (vtr after index) 1 3'='actualPVT before (succ3 index)')

Load_correct 'before' 'after' :=
'faulty ONE'='False' => load_correct 'before' 'after' 'ONE'
& 'faulty TWO'='False' => load_correct 'before' 'after' 'TWO'
& 'faulty THREE'='False' => load_correct 'before' 'after' 'THREE'
& 'faulty FOUR'='False' => load_correct 'before' 'after' 'FOUR'

Load = Iterate (#3) IcNetStep

Load_correct_proper 's' :=
Load_correct 's' & Sync 'XNG1' 'Load s'
Load_correct_lemma :=
Preconditions 's' => Load_correct_proper 's'

********************************************************************* Specification of the exchange cycles.

xng1_correct 's' 'index' :=
('faulty (succ index)='False'
 => 'arrayof (vtr s index) 2 2'='arrayof (vtr s (succ index)) 1 1')
& ('faulty (succ2 index)='False'
 => 'arrayof (vtr s index) 3 3'='arrayof (vtr s (succ2 index)) 1 1')

xng2_correct 's' 'index' :=
('faulty (succ index)='False'
 => 'arrayof (vtr s index) 2 3'='arrayof (vtr s (succ index)) 1 2')
& ('faulty (succ3 index)='False'
 => 'arrayof (vtr s index) 3 2'='arrayof (vtr s (succ3 index)) 1 2')

xng3_correct 's' 'index' :=
('faulty (succ2 index)='False'
 => 'arrayof (vtr s index) 2 1'='arrayof (vtr s (succ2 index)) 1 3')
& ('faulty (succ3 index)='False'
 => 'arrayof (vtr s index) 3 2'='arrayof (vtr s (succ3 index)) 1 3')

Xng1_correct 's' :=
'faulty ONE'='False' => xng1_correct 's' 'ONE'
& 'faulty TWO'='False' => xng1_correct 's' 'TWO'
& 'faulty THREE'='False' => xng1_correct 's' 'THREE'
& 'faulty FOUR'='False' => xng1_correct 's' 'FOUR'

Xng2_correct 's' :=
'faulty ONE'='False' => xng2_correct 's' 'ONE'
& 'faulty TWO'='False' => xng2_correct 's' 'TWO'
& 'faulty THREE'='False' => xng2_correct 's' 'THREE'
& 'faulty FOUR'='False' => xng2_correct 's' 'FOUR'

Xng3_correct 's' :=
'faulty ONE'='False' => xng3_correct 's' 'ONE'
& 'faulty TWO'='False' => xng3_correct 's' 'TWO'
& 'faulty THREE'='False' => xng3_correct 's' 'THREE'
& 'faulty FOUR'='False' => xng3_correct 's' 'FOUR'

Xng = Iterate (#2) IcNetStep

Xng1_correct_lemma :=
Xng2_correct_lemma :=
(Proper_icnet 's' & Sync 'XNG2' 's') =>
(Xng2_correct 'Xng s' & Sync 'XNG3' 'Xng s' & Xng1_correct 'Xng s')

Xng3_correct_lemma :=
(Proper_icnet 's' & Sync 'XNG3' 's' & Xng1_correct 's' & Xng2_correct 's') =>
(Xng3_correct 'Xng s' & Sync 'CMPP' 'Xng s' & Xng1_correct 'Xng s' & Xng2_correct 'Xng s')

The compute and output cycles:
An array is a function of type :: INDEX->INDEX->data
so it represents a vector of four values, one for each index.
This representation makes it easy to rotate the vector, since the rotated vector is obtained by composing with the function "succ".
Now we can say that an array A is consistent if, for all non-faulty indices, i and j, the vectors A_i and A_j, are related by the appropriate rotation, e.g. if j = succ_2 i then (A_i).succ_2 equals (A_j).

Consistent 'array' 'index' :=
('faulty (succ index)'='False'=>'(array index).succ='array (succ index)')
& ('faulty (succ2 index)'='False'=>'(array index).succ2='array (succ2 index)')
& ('faulty (succ3 index)'='False'=>'(array index).succ3='array (succ3 index)')

Consistent 'array' :=
'faulty ONE'='False'=> IndexConsistent 'array' 'ONE'
& 'faulty TWO'='False'=> IndexConsistent 'array' 'TWO'
& 'faulty THREE'='False'=> IndexConsistent 'array' 'THREE'
& 'faulty FOUR'='False'=> IndexConsistent 'array' 'FOUR'

maj_val i <<ftc,vtr,in>> index = get_maj_val i (maj_of (vtr index))
Compute = Iterate (#1) IcNetStep
Compute_correct_lemma :=
(Proper_icnet 's' & Sync 'CMPP' 's'
 & Proper_icnet 'before' & Load_correct 'before' 's'
 & Xng1_correct 's' & Xng2_correct 's' =>
 => (Consistent 'a_icvec before' (Compute s))
 & Sync 'OUT1' 'Compute s')

We want the final correctness condition to refer only to the states of the processors, not the voters. So the icvec that we state the condition on is:

icvec init final index ONE = actualPVT init index
icvec init final index TWO = maj_val 1 final index
icvec init final index THREE = maj_val 2 final index
icvec init final index FOUR = maj_val 3 final index

maj_val i <<ftc,vtr,inlist>> index = get_special_registerVT i (maj_of (vtr index))
Compute = Iterate (#1) IcNetStep
Compute_correct_lemma :=
(Proper_icnet 's' & Sync 'CMPP' 's'
 & Proper_icnet 'before' & Load_correct 'before' 's'
 & Xng1_correct 's' & Xng2_correct 's' & Xng3_correct 's')
 => (Consistent 'a_icvec before' (Compute s))
 & Sync 'OUT1' 'Compute s')

We want the final correctness condition to refer only to the states of the processors, not the voters. So the icvec that we state the condition on is:
icvec init final index ONE = actualPVT init index
icvec init final index TWO = get_special_register VT1 final index
icvec init final index THREE = get_special_register VT2 final index
icvec init final index FOUR = get_special_register VT3 final index
get_special_register saddr <<ftc,vtr,inlist>> index = sregof (ftc index) saddr
So to finish of the proof of correctness we need only show that for non-faulty index, 'icvec init (Output s) index'='a_icvec init s index'
Output = Iterate (#2) IcNetStep

output_correct 's' 'index' :=
'icvec init (Output s) index'='a_icvec init s index'

Output_correct 's' :=
('faulty ONE'='False' => output_correct 's' 'ONE')
& ('faulty TWO'='False' => output_correct 's' 'TWO')
& ('faulty THREE'='False' => output_correct 's' 'THREE')
& ('faulty FOUR'='False' => output_correct 's' 'FOUR')

Output_correct_lemma :=
(Proper_icnet 's' & Sync 'OUT1' 's' & Bytecount_sync 'BYTE1' 's')
=> Output_correct 's'

Twelve_cycle = Output.Compute.Xng.Xng.Xng.Load
MainTheorem := Preconditions 's' => Consistent 'icvec s (Twelve_cycle s)'

To chain these lemmas together we need:

Connect_lemma_1_1 :=
(Proper_icnet 's' & Sync 'cs' 's' & 'cs=LDPl'='False')
=> Proper_icnet 'IcNetStep s'

Connect_lemma_1_2 :=
(Proper_icnet 's' & Sync 'cs' 's' & 'cs=LDPl'='False')
=> Sync 'next_voterstate cs' 'IcNetStep s'

('faulty ONE'='False' => 'go_of (vtr s ONE)'='True')
& ('faulty TWO'='False' => 'go_of (vtr s TWO)'='True')
& ('faulty THREE'='False' => 'go_of (vtr s THREE)'='True')
& ('faulty FOUR'='False' => 'go_of (vtr s FOUR)'='True')
& Sync 'LDPl' 's'

Connect_lemma_1_4 :=
Preconditions 's' => (Proper_icnet 'IcNetStep s' & Ready 'IcNetStep s')

Connect_lemma_1_5 :=
(Proper_icnet 's' & Ready 's')=> Proper_icnet 'IcNetStep s'

Connect_lemma1 :=
Connect_lemma_1_1 & Connect_lemma_1_2 & Connect_lemma_1_3 & Connect_lemma_1_4

Connect_lemma3 :=
(Proper_icnet 's' & Sync 'XNG11' 's' & Load_correct 'before' 's') =>
Load_correct 'before' 'Xng s'

Connect_lemma4 :=
(Proper_icnet 's' & Sync 'XNG21' 's' & Load_correct 'before' 's') =>
Load_correct 'before' 'Xng s'

Connect_lemma5 :=
(Proper_icnet 's' & Sync 'XNG31' 's' & Load_correct 'before' 's') =>
Load_correct 'before' 'Xng s'

Connect_lemma6 := Preconditions 's' =>
Bytecount_sync 'BYTE1' 'Compute(Xng(Xng(Xng(Load s))))'

**********************************************************************
| Here's another theorem that expresses a property useful from the point of |
| view of a programmer using ICOP. It ensures that the system performs IC  |
| computation on the contents of SREG[PVT] in the cycle in which ICOP was  |
| executed, provided the instruction immediately following ICOP is not    |
| SADD. The following theorem, which has not been proved yet, can be proved |
| using the above MainTheorem as a lemma.                              |
|**********************************************************************
| After 12 cycles, each non-faulty processor should have a vector       |
| of four values: the initial value of its PVT special register         |
and the final values in the special register VT1, VT2, and VT3.
Among the non-faulty processors, these vectors should be related
by a rotation.

anothericvec init final index ONE = get_special_register PVT init index
anothericvec init final index TWO = get_special_register VT1 final index
anothericvec init final index THREE = get_special_register VT2 final index
anothericvec init final index FOUR = get_special_register VT3 final index

Note that the expression "icvec init final index" is actually
a function on the type INDEX, and represents the vector of four values.

ResultConsistent 's' := Consistent 'anothericvec s (Iterate #12 IcNetStep s)'

AnotherMainTheorem :=
    Preconditions 's' & Next_instrn_isnot_SADD 's' => ResultConsistent 's'
Array s = arrayof.(vtr s)

Verification of the FtCayuga Fault-Tolerant Microprocessor System

Volume 2: Formal Specification and Correctness Theorems

Mark Bickford and Mandayam Srivas

ORA Corporation
301A Harris B. Dates Drive
Ithaca, NY 14850-1313

Technical Monitor: Ricky W. Butler, Langley Research Center
Task 1 Final Report
Volume 1 published as NASA CR-4381.

This is the second volume of a two-volume report that presents a formal specification and verification of a property of a quadruplicately redundant fault-tolerant microprocessor system design. This volume gives a complete listing of the formal specification of the system and the correctness theorems that were proved. The system performs the task of attaining interactive consistency among the processors using a special instruction on the processors. The design is based on an algorithm proposed by Pease, Shostak and Lamport. The microprocessor used in the system is called FtCayuga, which was designed by extending another formally verified microprocessor MiniCayuga. The property verified ensures that an execution of the special instruction by the processors correctly accomplishes interactive consistency, provided certain preconditions hold, using a computer-aided hardware design verification tool, Spectool, and the theorem prover, Clio, both of which were developed at ORA. A major contribution of the work is the demonstration of a significant fault-tolerant hardware design that is mechanically verified by a theorem prover.
