Abstract

The dependencies between the different parameters of a leader in lightning theoretically are obtained. The physical mechanism of the instability leading to the formation of the streamer zone is supposed. The instability has the wave nature and is caused by the self-influence effects of the space charge. Using a stability condition of the leader propagation a dependence between the current across a leader head and the its velocity of moving is obtained. The dependence of the streamer zone length on the gap length is obtained. It is shown that the streamer zone length is saturated with the increasing of the gap length. A comparison of the obtained dependences with the experimental data is resulted.

1 Introduction

A consideration of leader discharge propagation is based on the investigation of charged particles moving in electric field. A particle moves in the potential created by all others charges. The calculation of self-consistent potential is a difficult mathematical problem. Therefore, it is important to construct an alternative approach for the analysis of such self-consistent problem. Particularly, an approach similar to the one used nonlinear wave theory for analysis of the self-influence effects in a nonlinear media turns out to be effective. At such approach leader process is described by the nonlinear wave equations of evolution type, which from the continuity equations for the particles and Poisson equation for the electric field may be obtained. Note, that the nonlinear wave equation being constructed for the complex wave function \( \Psi(x,y,z,t) \), determined from the condition \( \phi = |\psi|^2 \), where \( \phi \) is the charge density. Such approach allows to understand the physical picture of many effects in leader process, in particular, the mechanism of instability, leading to the streamer corona formation.

In this paper a qualitative consideration of physical processes in a leader discharge caused by the self-influence effects is suggested.

2 Streamer zone formation

Leader process begins from the formation of streamer corona, consisting of multitude individual streamers. It is known that the streamers formation is caused by the avalanche-streamer transition. However a series of peculiarities of streamer have not a physical explanation so far. In particular the physical picture of the keeping of streamer head radius along the all its trajectory is not known. It is necessary to solve the two-dimensional equations for explanation of this effect:

\[
\begin{align*}
\frac{\partial n}{\partial t} & = \frac{j}{e} + \alpha \nu n + \nu, \\
\frac{\partial \nu}{\partial t} & = \nu \eta n + \nu, \\
\frac{\partial \nu}{\partial t} & = \frac{\nu}{\eta} (p - n),
\end{align*}
\]

\( \frac{j}{e} = j_p + j_d + j_n \) is the current density, \( n \) and \( p \) are number density of electrons and positive ions, respectively, \( \alpha \) is the ionization coefficient, \( \nu \) is the drift velocity, \( D \) is the diffusion coefficient, \( \nu \) is the charges produced due to the gas photoionization per volume and time.
luted as follows:

\[ q = \frac{4\pi\varepsilon_0^3}{\varepsilon^2} \int \frac{E_x(x)}{\alpha^2} \, dx = \frac{4\pi\varepsilon_0^3}{\varepsilon^2} \int \frac{E_x(x)}{\alpha^2} \, dx = \frac{4\pi\varepsilon_0^3}{\varepsilon^2} \int \frac{E_x(x)}{\alpha^2} \, dx \]

At the \( \varepsilon = 24 \text{ kV/cm} \) and \( \alpha = 10^2 \text{ cm}^{-1} \) in air we obtain, that the \( p = 2.4 \times 10^{-12} \Omega \cdot \text{cm} \) or \( \mathcal{N}_e = \frac{1}{\alpha} \). In \( \mathcal{N}_e \) for the development of streamer the \( q \) is necessary.

Then the \( \alpha = 0.75 \times 10^{-10} \text{ cm} \) and the streamer charge is equal to \( q = 1.6 \times 10^{-12} \Omega \cdot \text{cm} \) or \( \mathcal{N}_e = \alpha \).

A process in the streamer channel influence on its development only up to distance \( \sim \frac{V_a}{V_0} \), where \( V_0 \) is the attachment coefficient (\( \sim 10^4 \text{ sec} \) in air). At further removing from the electrode a streamer head loses the conductive connection with it, but the necessary intensification of field on the head is ensured because of its polarization in the external electric field.

A such mechanism allows to explain the dependence of streamer velocity on the value of external electric field. So, from the system (1-3) may be obtained:

\[ v_{hc} = \frac{E_x}{3\sqrt{\varepsilon}} \approx v + \alpha \sqrt{\varepsilon} + \omega, \]

where \( \alpha(E) = \frac{A}{B(E)} \), \( E \) is the electric field, \( A \) and \( B \) are constant, \( v' = v_{hc} \sim \sqrt{\varepsilon} \), \( v_{hc} \sim \frac{E_{cr}}{E,} \)

From here one can see that the streamer velocity has the threshold character of dependence on the external electric field. This leads to the quickly stopping of streamer at the decrease of field lower the critical value \( E_{cr} \).

In the nonuniform gaps the critical field is reached only near by electrode. However, in the long gaps only the numerous streamers are propagated, which form the streamer zone. Fluctuation of physical mechanism of instability leading to the formation of streamer zone is of interest. When the charge density reaches the critical value, the breaking into the threads (streamers) is occurring, i.e., the analogy with the breaking of light beam or acoustic wave in nonlinear media is exist.

Note, that the instability leading to the formation of streamer zone has the wave nature and is not connected with the temperature instability. The role of critical power in this case the critical charge density in the leader head plays, and besides the number of streamers is equal to \( \mathcal{N}_{mz} = q/\rho \) at the insulate into the gap of charge \( Q \).

3 Physical picture of leader propagation

Characteristic peculiarity of propagation both positive and negative leader is the essential influence of the space charge of the streamer zone. Formation of a new leader head and its moving is caused owing to the self-influence processes and the ability of streamers to propagate in the region of the weekly field.

3.1 Pinching effect in the leader front

As the mechanism of a pinch usually the low-temperature overheating instability is suggested \( \mathcal{I} \). However the time of pinching in this case is determined by the thermal processes. A next physical picture of the pinch not connected with the thermal processes may be suggested. Because of the nonuniform distribution of conductivity \( \sigma(x) \) in the leader front the distribution of charges created in this field turn out to be also nonuniform, i.e., the nonuniform distribution of conductivity \( \sigma(x) \) is formed. The axis region of the head has the greater conductivity, therefore the electric field is quoted from there toward quickly than from periphery regions. The quickest time of field is determined by the Maxwell relaxation time of charges \( \tau_r \sim \frac{1}{\sqrt{\varepsilon}} \). Thus the cross electric field is created pinching the charges into the axis region and leading to the pinching of the head. The pinching is determined by the degree of nonuniformity of conductivity and Maxwell relaxation time \( \tau_r \).

3.2 Plasma clots formation

It is known \( \mathcal{I} \) that at the front of the streamer zone of negative leader the plasma clots are formed, from which in the opposite direction the positive volume leader is propagated. A physical mechanism of the plasma clot formation is unclear. Lower the physical mechanism of plasma clot formation is suggested. It is known that the streamers starting out of the leader tip are connected with the leader head galvanically up to the distance approximately of few centimeters. A maximum length is determined by the disintegration time of the plasma in the gap parts of the streamer channel \( \mathcal{L}_{max} = \frac{1}{v_0} \), \( v_0 = \sqrt{\varepsilon} \) is the electron detachment frequency. This time in air is equal to \( t \sim 10^{-5} \text{ sec} \). Further propagation of the streamer is stopped at the absence of the galvanic connection with the leader tip. The losses of the energy are compensated at the expense of the external electric field energy. The plasma clot at the length of approximately 1 cm are polarized in the electric field. A force acting on the dipoles in the nonuniform electric field equal to

\[ \vec{F} = \rho \vec{E}, \]

where \( \rho \) is the dipole moment, \( \vec{E} \) is the electric field.

Hence it follows that the plasma dipoles draw in the strong field region, i.e., the focusing of dipoles take place. The formation of plasma clot not depends on the polarity of leader and take place also in a positive leader.

3.3 Stepped leader propagation mechanism

A continuous or stepped propagation of a leader to be take place in the dependence on the polarity and the humidity. A negative leader propagates only in the stepped form. A positive leader may to propagate both continuous and stepped forms.

Two forms of the stepped propagation of positive leader may be suggested. The first of these is connected with the feeding difficulties of the leader channel, and the second with the formation of plasma clot at the front of streamer zone. An analogically to the negative leader. In the first case the time pause between the steps or the flashing of the leader channel is not connected with the length of the streamer zone and the velocity of the leader and not has a periodic character. In the second case the pause time between the steps by the velocity of the leader and the length of streamer zone is determined. This it seems leads to the decrease of the time interval between the steps when the leader approaches to the ground. A schematic picture of stepped propagation of a leader is presented in fig.1.
It is seen from fig. 1 that the pause time between the steps depends on the velocities of the positive \( C_+ \) and negative \( C_- \) leaders and the streamer zone length \( \zeta_+ \). Effective velocity of the stepped leader propagation or the mean leader velocity is determined as the

\[
\text{eff} = \frac{H}{t} = \frac{N \cdot t}{t} = \frac{\ell_+}{t},
\]

(11)

where \( H \) is the gap length, \( t \) is the full time of leader propagation, \( N \) is the number of steps.

As it follows from (11) at \( \ell = \text{const} \), the effective velocity \( n \) of stepped leader grows with the increasing of leader head radius.

4 Optimal parameters of leader
A stability propagation of a leader is possible at the establishment of balance between the processes in the channel, leader head and streamer zone (fig. 2). In particular, a full current flowing in each these regions must be the same. In a channel the current is determined in the main by the conduction current

\[
e_i = C \cdot E, \quad \ell_+, \ell_-, \quad (12)
\]

where \( C \) is the channel radius, \( E \) is the conductivity.

In a streamer zone the displacement current caused by the moving of charges flows

\[
\zeta_i = \zeta_0 \cdot \zeta_2, \quad (13)
\]

and in the leader velocity.

Finally, at the front of streamer zone the "clean" displacement current, not connected with the charges moving takes place

\[
\zeta_2 = \frac{E \cdot S}{\varepsilon}. \quad (14)
\]

where \( S \) is the area of streamer zone front. Note that \( \ell = \ell_+ + \ell_+ \) and \( E = E_+ \), where \( E_+ \) is the electric field in the streamer zone, \( \ell_2 \) is the streamer zone length. Hence it follows the correlation

\[
\zeta_1 \sim \zeta_2 \sim \ell_+ \zeta_2 \sim \ell_+ \cdot \ell_+ \sim \ell_+ \cdot \ell_+ \sim \ell_+ \cdot \ell_+, \quad (15)
\]

where \( \zeta_2 \) is the derivative of electric field along the propagation direction of leader at the streamer zone front, \( \zeta_+ \) is the current density in the leader head, \( \zeta_2 \) is the radius of leader head.

Note that the electric field in the streamer zone is kept along the all its length \( \ell_2 \).

A pinch of leader head takes place at the reaching of critical power \( \omega_1 = \omega_2 + \omega_3 \) where \( \omega_1 \sim \omega_2 \sim \omega_3 \). Then from (15) we obtain the correlation

\[
\zeta_2 \sim \ell_+ \cdot \ell_+ \cdot \ell_+ \cdot \ell_+.
\]

4.1 The velocity of leader

The velocity of leader analogically to the velocity of streamers is determined by the effective ionization coefficient \( \alpha_{eff} \) before the head:

\[
\zeta_2 \sim \ell_+ \cdot \ell_+ \cdot \ell_+ \cdot \ell_+, \quad (16)
\]

It is seen from (16), that at the \( \ell_+ \) the velocity of leader is constant. Therefore

\[
\zeta_2 \sim \ell_+ \cdot \ell_+ \cdot \ell_+ \cdot \ell_+, \quad (17)
\]

and the velocity

\[
\zeta_2 \sim \ell_+ \cdot \ell_+ \cdot \ell_+ \cdot \ell_+.
\]

The velocity dependence on the current flowing across the leader head is presented in fig. 3.

4.2 The streamer zone length

From (15) the equation for the determining of the dependence of streamer zone length on the gap \( H \) may be obtained:

\[
\zeta_2 = \frac{\varepsilon \cdot \ell_+}{\varepsilon_+ \cdot \ell_+} \cdot \ell_+ \cdot \ell_+ \cdot \ell_+ \cdot \ell_+ \cdot \ell_+ \cdot \ell_+, \quad (18)
\]

It is known that the electric field intensity is determined by the equation

\[
E = \text{grad } \mathcal{A},
\]

where \( \mathcal{A} \) is the sum of the potential created by the electrode and the potential \( \mathcal{A}_e \) created by the space charge of the streamer zone. The potential \( \mathcal{A}_e \) is the solution of Poisson equation \( \Delta \mathcal{A} = 4 \pi \rho \) and may be obtained from the integral equation

\[
\mathcal{A} = \int \frac{\varepsilon_+ \cdot \ell_+}{\varepsilon_+ \cdot \ell_+} \cdot \ell_+ \cdot \ell_+ \cdot \ell_+ \cdot \ell_+ \cdot \ell_+ \cdot \ell_+, \quad (19)
\]

where \( \varepsilon_+ \cdot \ell_+ \) is the radius of electrode, \( \ell_+ \) is the surface charge density, \( \mathcal{A}_e \) is the electric field on the electrode surface, \( \ell_+ \) is the distance between the element of charge and the point of observing, \( \ell_+ \) is the angle of integration. The distribution of the charge density along the radius of streamer zone may be determined on the known electric field from the equation

\[
\text{div } \mathcal{A} = 4 \pi \rho, \quad (20)
\]

Since the electric field intensity in the streamer zone is not changed along the all...
where \( \mathbf{E} = \mathbf{E}(x, y, z) \) is the electric field near the leader head.Integrals (19) may be calculated analytically.Calculating the derivative \( \frac{\partial \mathbf{E}}{\partial z} \) and substituting it to the equation (18) the equation for determination of the dependence \( \xi_{th} = \xi(h) \) may be obtained.Fig.4 shows the calculated value of streamer zone length \( \xi_{th} \) as a function of gap length \( H \).

![Graph showing \( \xi_{th} \) as a function of \( H \).](image)

It is found that when the influence of electrode is not take into accounted the streamer zone length grows linearly to the gap length (curve 1). The streamer zone length is saturated when the influence of electrode is take into accounted (curve 2).

5 Fractal nature of lightning

It is known that even at the identical external conditions (gap geometry, atmosphere conditions, applied voltage) the characteristics of discharge behave accidentally.In particular the trajectory of lightning represents something crooked line changing from case to case.However it may be showed that the channel dynamics is described by the determinic equations,i.e., the chance picture of trajectory is determined by the internal properties of leader, but not the external chance influences.A series of quantitative characteristics may be introduced which allow to differ the one picture of discharge from other. These are fractal dimensions.So, the channel length of lightning \( L \) measured by the put on the sections with the length \( \xi \) depend on the minimal length \( L_{min} \) by the degree manner

\[
L(\xi) = \xi \left( \frac{L_{min}}{\xi} \right)^{D},
\]

where \( D \) in the fractal dimension, changing in the interval \( 1 < D < 2 \). Fractal dimension \( D \) changes at the changing of characteristic length of straight sections of channel and its orientation angle. In one's t urn this characteristic length is connected with the streamer zone length that determines the parameters of the electromagnetic radiation of lightning. Therefore the amplitude-frequency characteristics of lightning radiation also possess by the fractal nature. This property may be used for the re-establishment of the channel parameters on the characteristics of the electromagnetic radiation.

A growth of streamer zone of leader may be described also on the basis of the growth law of branching physical system, possessing by the fractal nature. The fractal dimension \( D \) of the streamer zone may be determined by means of calculation the number of streamers branches (or the streamers heads), keeping in the sphere with radius \( R \) at different \( R \):

\[
\rho(R) = \int \rho(t) t^{D-1} dt \sim R^{D},
\]

where \( \rho(t) \) is the density distribution of streamers heads \( \mathbf{H} \) in the space dimension. Hence it follows that the charge density distribution satisfies the law

\[
\rho(R) \sim R^{D-1},
\]

It is known that the electric field intensity in the streamer zone \( \xi_{th} \) is a function of gap length \( H \). From the Poisson equation \( \nabla^2 \phi = \rho \) we obtain, that this take place at the \( \rho(\xi) \xi^{D-1} \), i.e., at the \( D = 2 \) in three-dimensional space. Therefore the streamer zone represent the fractal structure with the dimension \( D = 2 \).

6 Discussion and conclusion

The dependences obtained above may be used at the calculating of leader parameters in lightning. Using the relations (17) we can evaluate the streamer zone length \( \xi_{th} \) or the leader head potential \( \phi \) of lightning. It is known [9] that the streamer zone length is equal to \( \xi_{th} = 1 \) m and \( \phi = 500 \) kV in the laboratory gaps at the leader current \( i_{c} = 1 \) A. A characteristic current of leader in lightning is equal to \( i_{c} \approx 100 \) A [6]. Hence we obtain that the characteristic streamer zone length is equal to \( \xi_{th} = 20 \) m and the potential of leader \( \phi = 10 MV \), that agrees with the experimental observations.

In table 1 some values of current in leader \( i_{c} \), radius of leader \( R \), potential of leader head \( \phi \), velocity of leader \( v_{c} \), and streamer zone length \( \xi_{th} \) for different gap length \( H \) are presented. At the current in leader \( i_{c} = 1 \) A the values of parameters are presented from the laboratory experiments in long air gap.

It is seen from table that the calculated values agree with the experimental data obtained for lightning. Added relations between the parameters are related to the leader stage of discharge. However these determine also the characteristics of discharge in the return stroke stage. So, streamer zone length determines a duration of return stroke current, connected with the neutralization of space charge around the channel. As was shown above, streamer zone length is saturated at the growth of gap length. This explains the slow change of the duration of return stroke current from case to case.

Note that streamer zone length also determines the amplitude value of return stroke current. The obtained correlations may be used at the determining of such parameters of lightning as the potential of cloud current and space charge neutralized by return stroke on the characteristics its electromagnetic radiation.
