Hampton, Virginia 23681-0001
Abstract

The popular QR algorithm for solving all eigenvalues of an unsymmetric matrix is reviewed. Among the basic components in the QR algorithm, it has been concluded from this study, that the reduction of an unsymmetric matrix to a Hessenberg form (before applying the QR algorithm itself) can be done effectively by exploiting the vector speed and multiple processors offered by modern high-performance computers.

Numerical examples of several test cases have indicated that the proposed parallel-vector algorithm for converting a given unsymmetric matrix to a Hessenberg form offers computational advantages over the existing algorithm. The time saving obtained by the proposed method is increased as the problem size increased.

I. Introduction

The algorithms for symmetric matrices [1-3] are highly satisfactory in practice. By contrast, it is impossible to design equally satisfactory algorithms for the nonsymmetric cases, which is needed in Controls-Structures Interaction (CSI) applications [1,4]. There are two reasons for this. First, the eigenvalues of a nonsymmetric matrix can be very sensitive to small changes in the matrix elements. Second, the matrix itself can be defective, so that there is no complete set of eigenvectors.

There are several basic building blocks in the QR algorithm, which is generally regarded as the most effective algorithm, for solving all eigenvalues of a real, unsymmetric matrix. These basic components of the QR algorithm are reviewed in Section II. Basic techniques to exploit the vector speed and multiple processors offered by modern high-performance computers are explained in Section III. An analysis of the Hessenberg reduction component in the QR algorithm is given in Section IV where both vector and parallel techniques are incorporated into the Hessenberg reduction component. Numerical examples are provided in Section V to evaluate the performance of the proposed method over the existing one. Conclusions and recommendations are given in Section VI. Finally, a listing of the Hessenberg reduction algorithm (in the form of Fortran coding) is provided in the appendix.

II. Basic Components of the QR Algorithm [3,5]

2.1 Balancing:
The idea of balancing is to use similarity transformations to make corresponding rows and columns of the matrix have comparable norms, thus reducing the overall norm of the matrix while leaving the eigenvalues unchanged.

The time taken by the balanced procedure is insignificant as compared to the total time required to find the eigenvalues. For this reason, it is strongly recommended that a nonsymmetric matrix need to be balanced before even attempting to solve for eigen-solutions.

2.2 Reduction to Hessenberg form:

The strategy for finding the eigensolution of an unsymmetric matrix is similar to that of the symmetric case. First we reduce the matrix to a simpler Hessenberg form, and then we perform an iterative procedure on the Hessenberg matrix. An upper Hessenberg matrix has zeros everywhere below the diagonal except for the first subdiagonal. For example, in the 6 x 6 case, the nonzero elements are:

\[
\begin{bmatrix}
X & X & X & X & X & X \\
X & X & X & X & X & X \\
0 & X & X & X & X & X \\
0 & 0 & X & X & X & X \\
0 & 0 & 0 & X & X & X \\
0 & 0 & 0 & 0 & X & X \\
\end{bmatrix}
\]

Thus, a procedure analogous to Gaussian elimination can be used to convert a general unsymmetric matrix to an upper Hessenberg matrix. The detailed coding of the Hessenberg reduction procedure is listed in subroutine OELMHS of the appendix.

Once the unsymmetric matrix has already been converted into the Hessenberg form, the QR algorithm [3,5] itself can be applied on the Hessenberg matrix to find all the real and complex eigenvalues. For completeness, detailed coding of the QR algorithm on the Hessenberg matrix is listed in subroutine HQR of the appendix.

III. Basic Techniques For Vector and Parallel Speeds

In this section, a simple example of matrix times vector is used to explain some basic vector and parallel techniques which are useful for Hessenberg reduction algorithm.

Given a 3x3 Matrix \( A = \begin{bmatrix} 2 & -1 & 0 \\ -1 & 2 & -1 \\ 0 & -1 & 1 \end{bmatrix} \) and a vector \( x = \{1,0,0\}^T \)

Here, the dimension of the system is \( N=3 \). The objectives are to develop efficient parallel-vector matrix times vector subroutines.
3.1 Row-by-Row conventional approach:

\[
\begin{align*}
DO & \ 1 \ I=1,N \\
DO & \ 2 \ J=1,N \\
B(I) & = B(I) + A(I,J) \times x(J) \\
2 & \ Continue \\
1 & \ Continue
\end{align*}
\]

It should be emphasized here that in this approach, the value of B(I) corresponds to the final answer.

3.2 Column-by-Column conventional approach:

\[
\begin{align*}
DO & \ 1 \ J = 1,N \\
DO & \ 2 \ I = 1,N \\
B(I) & = B(I) + A(I,J) \times x(J) \\
2 & \ Continue \\
1 & \ Continue
\end{align*}
\]

It should be emphasized here that in this approach, the value of B(I) does NOT correspond to the final answer. B(I) only gives the partial (or incomplete) answer and it will give the final answer only if all values of J have been executed. It is also observed that x(J) is a constant (with respect to loop 2), thus the operations involved in loop 2 can be stated generally as: A new vector \( B = \) Old vector \( B + \) Constant * another vector \( A \).

3.3 Row-by-Row “vector unrolling” approach:

Assuming the dimension N of the system is large, say N = 600, then the algorithm in Section 3.1 can be modified to improve the vector speed as following:

\[
\begin{align*}
NUNROL & = 2 \\
DO & \ 1 \ I = 1,N, \ NUNROL \\
DO & \ 2 \ J = 1,N \\
B(I) & = B(I) + A(I,J) \times x(J) \\
B(I+1) & = B(I+1) + A(I+1,J) \times x(J) \\
2 & \ Continue \\
1 & \ Continue
\end{align*}
\]

The operations involved inside loop 2 is referred to as “dot product” operations.

3.4 Column-by-Column “loop-unrolling” approach

The algorithm in Section 3.2 can be modified to improve the vector speed performance
\[ \text{NUNROL} = 2 \]
\[ \text{DO 1 } J = 1, N, \text{ NUNROL} \]
\[ \text{DO 2 } I = 1, N \]
\[ B(I) = B(I) + A(I,J) \times x(J) \]
\[ \quad + A(I,J+1) \times x(J+1) \]
\[ 2 \text{ Continue} \]
\[ 1 \text{ Continue} \]

The operations involved inside loop 2 is referred to as "saxpy" operations.

3.5 Parallel-vector loop-unrolling approach:

For multiple processors, the algorithm in Section 3.4 can be modified to take advantage of parallel speed (in addition to vector speed)

\[ \text{NUNROL} = 2 \]
\[ \text{Parallel DO 1 } J = 1, N, \text{ NUNROL} \]
\[ \text{DO 2 } I = 1, N \]
\[ B(I) = B(I) + A(I,J) \times x(J) \]
\[ \quad + A(I,J+1) \times x(J+1) \]
\[ 2 \text{ Continue} \]
\[ 1 \text{ Continue} \]

In this algorithm, each value of the index J (of loop 1) is assigned to different processors for parallel computation.

IV. An Analysis of the Hessenberg Reduction Algorithm

A careful look into the Hessenberg reduction algorithm of Section 2.2 and subroutine OELMHS of the appendix will reveal that the most intensive computations of Subroutine OELMHS occur in loops 140 and 150 of the code. Furthermore, the Fortran statement inside loop 150 can be generally expressed as:

\[ A(J, M) = A(J,M) + Y \times A(J,I) \]

or

\[ \text{A new vector } A(J, -) = \text{old vector } A(J, -) + (a \text{ constant}) \times \text{another vector } A(J,*) \]

Thus, one can immediately see the similarity between loops 160 & 150 of Subroutine OELMHS and loops 1 & 2 of the matrix times vector algorithm presented in Section 3.2. From the experience we have had in section 3.5, we can therefore similarly apply the parallel computations in loop 160 and loop-unrolling (here NUNROL = 8 is used) for vector computations in loop 150 of subroutine OELMHS.

For completeness, the entire parallel-vector version of the Hessenberg reduction, and the original QR algorithms are listed in the Appendix.
V. Numerical Examples

In order to evaluate the numerical accuracy and the performance of the new parallel-vector Hessenberg Reduction portion of the QR algorithm, the following numerical tests are performed.

Example 1:
Find all eigenvalues of the following 2 x 2 unsymmetric matrix

\[
A = \begin{bmatrix}
2 & -6 \\
8 & 1
\end{bmatrix}
\]

The analytical eigen-value solution for this problem is:

\[
\lambda_1 = 1.5 + 6.91 \hat{i}
\]

\[
\lambda_2 = 1.5 - 6.91 \hat{i}
\]

which also matches with the computer solution.

Example 2:
In this example, the unsymmetric matrix \([A]_{m \times n}\) is automatically generated for any dimension \(N\) of the matrix \([A]\) (please refer to the code given in the Appendix). The accuracy and the performance of the new parallel-vector Hessenberg reduction algorithm is compared to the original subroutine. Since the QR algorithm itself is highly sequential, no attempts to parallelize and vectorize the QR algorithm have been made. However, the total solution time of the complete unsymmetric eigensolution process (= Hessenberg Reduction Time and QR Time) are also presented in Tables 1 and 2.
Table 1: Vector Performance on the Alliant Using etime (t), fortran -DAS -O -alt -l -OM

VI. Conclusions and Recommendations:

The most popular and effective procedure to solve all eigenvalues of an unsymmetric matrix involved 2 major tasks, namely Hessenberg reduction form and QR algorithm on the Hessenberg matrix. In general, QR algorithm requires between 2 to 3 times more computational effort than the Hessenberg reduction algorithm.

In this study, the parallel and vector speeds of the Hessenberg reduction algorithm has been developed and implemented on the Alliant and Cray-YMP (Reynolds) computers. Numerical results have indicated that the proposed parallel-vector Hessenberg reduction algorithm does offer computational advantages (without losing its accuracy) as compared to the existing algorithm. The time saving is more significant as the problem size increased. Further research work is critically needed to improve the unsymmetric eigensolution procedure (using the QR, or another better, new parallel algorithm).

Acknowledgments:

This research work was supported by a NASA Task NAS 1-18584-122, and Mr. Joseph Walz was the NASA technical monitor.

APPENDIX

Parallel-Vector Hessenberg Reduction And Sequential QR Algorithm [5]
This is a working version of "unsymmetrical" eigen-solver on the sun386 work station. On the Cray-YMP (Reynold or Sabre), this "exact" same version should offer good vector & parallel speed (only for subroutine to perform Hessenberg reduction). For SMALL problems, the improvements due to parallel-vector Hessenberg is NOT MUCH. However, for LARGE problems, since the Hessenberg reduction timing becomes more important (as compared to the TOTAL eigen-solution time), the total time saving for the entire eigen-solution process is also very significant.

Since this version was developed specifically for CSI applications (according to Peiman's specifications/requirements), ALL EIGENVALUES (and NONE of the corresponding EIGENVECTORS) of an N by N squared unsymmetrical matrix are found.

"ARTIFICIAL" datas of various sizes (N = 2 ----> 800) with ALL REAL and MIXED REAL & COMPLEX eigenvalues have been verified (by comparing the results obtained by the original unsym. eigen-sol. taken from ORACLE and the modified version from the ODU team, and also by HAND)

SUBROUTINE BALANC(NM,N,A,LOW,IGH,SCALE)
C
INTEGER I,J,K,L,M,N,JJ,NM,IGH,LOW,EXC
REAL A(N,N),SCALE(N)
LOGICAL NOCONV
C
THIS SUBROUTINE IS A TRANSLATION OF THE ALGOL PROCEDURE BALANCE,
NUM. MATH. 13, 293-304(1969) BY PARLETT AND REINSCH.
THIS SUBROUTINE BALANCES A REAL MATRIX AND ISOLATES
EIGENVALUES WHENEVER POSSIBLE.
ON INPUT

NM MUST BE SET TO THE ROW DIMENSION OF TWO-DIMENSIONAL
ARRAY PARAMETERS AS DECLARED IN THE CALLING PROGRAM
DIMENSION STATEMENT.

N IS THE ORDER OF THE MATRIX.

A CONTAINS THE INPUT MATRIX TO BE BALANCED.

ON OUTPUT

A CONTAINS THE BALANCED MATRIX.

LOW AND IGH ARE TWO INTEGERS SUCH THAT A(I,J)
IS EQUAL TO ZERO IF
(1) I IS GREATER THAN J AND
(2) J = 1, ..., LOW-1 OR I = IGH+1, ..., N.

SCALE CONTAINS INFORMATION DETERMINING THE
PERMUTATIONS AND SCALING FACTORS USED.

SUPPOSE THAT THE PRINCIPAL SUBMATRIX IN ROWS LOW THROUGH IGH
HAS BEEN BALANCED, THAT P(J) DENOTES THE INDEX INTERCHANGED
WITH J DURING THE PERMUTATION STEP, AND THAT THE ELEMENTS
OF THE DIAGONAL MATRIX USED ARE DENOTED BY D(I,J). THEN
SCALE(J) = P(J), FOR J = 1, ..., LOW-1
= D(J,J), J = LOW, ..., IGH
= P(J) J = IGH+1, ..., N.

THE ORDER IN WHICH THE INTERCHANGES ARE MADE IS N TO IGH+1,
THEN 1 TO LOW-1.

NOTE THAT 1 IS RETURNED FOR IGH IF IGH IS ZERO FORMALLY.

THE ALGOL PROCEDURE EXC CONTAINED IN BALANCE APPEARS IN
BALANC IN LINE. (NOTE THAT THE ALGOL ROLES OF IDENTIFIERS
K,L HAVE BEEN REVERSED.)

QUESTIONS AND COMMENTS SHOULD BE DIRECTED TO BURTON S. GARBOW,
MATHEMATICS AND COMPUTER SCIENCE DIV, ARGONNE NATIONAL LABORATORY

THIS VERSION DATED AUGUST 1983.

SUBROUTINE HQR(NM,N,LOW, IGH,H,WR,WI,IERR)

INTEGER I,J,K,L,M,N,EN,LL,MM,NA,NM,IGH,ITN,ITS,LOW,MP2,ENM2,IERR
REAL H(N,N),WR(N),WI(N)
REAL P,Q,R,S,T,W,X,Y,ZZ,NORM,TST1,TST2
LOGICAL NOTLAS

THIS SUBROUTINE IS A TRANSLATION OF THE ALGOL PROCEDURE HQR,
NUM. MATH. 14, 219-231(1970) BY MARTIN, PETERS, AND WILKINSON.

THIS SUBROUTINE FINDS THE EIGENVALUES OF A REAL
UPPER HESSSENBERG MATRIX BY THE QR METHOD.
ON INPUT

NM MUST BE SET TO THE ROW DIMENSION OF TWO-DIMENSIONAL
ARRAY PARAMETERS AS DECLARED IN THE CALLING PROGRAM
DIMENSION STATEMENT.

N IS THE ORDER OF THE MATRIX.

LOW AND IGH ARE INTEGERS DETERMINED BY THE BALANCING
SUBROUTINE BALANC. IF BALANC HAS NOT BEEN USED,
SET LOW=1, IGH=N.

H CONTAINS THE UPPER HESSENBERG MATRIX. INFORMATION ABOUT
THE TRANSFORMATIONS USED IN THE REDUCTION TO HESSENBERG
FORM BY ELMHES OR ORTHES, IF PERFORMED, IS STORED
IN THE REMAINING TRIANGLE UNDER THE HESSENBERG MATRIX.

ON OUTPUT

H HAS BEEN DESTROYED. THEREFORE, IT MUST BE SAVED
BEFORE CALLING HQR IF SUBSEQUENT CALCULATION AND
BACK TRANSFORMATION OF EIGENVECTORS IS TO BE PERFORMED.

WR AND WI CONTAIN THE REAL AND IMAGINARY PARTS,
RESPECTIVELY, OF THE EIGENVALUES. THE EIGENVALUES
ARE UNORDERED EXCEPT THAT COMPLEX CONJUGATE PAIRS
OF VALUES APPEAR CONSECUTIVELY WITH THE EIGENVALUE
HAVING THE POSITIVE IMAGINARY PART FIRST. IF AN
ERROR EXIT IS MADE, THE EIGENVALUES SHOULD BE CORRECT
FOR INDICES IERR+1,...,N.

IERR IS SET TO
ZERO FOR NORMAL RETURN,
J IF THE LIMIT OF 30*N ITERATIONS IS EXHAUSTED
WHILE THE J-TH EIGENVALUE IS BEING SOUGHT.

QUESTIONS AND COMMENTS SHOULD BE DIRECTED TO BURTON S. GARBOW,
MATHEMATICS AND COMPUTER SCIENCE DIV, ARGONNE NATIONAL LABORATORY

THIS SUBROUTINE IS A TRANSLATION OF THE ALGOL PROCEDURE ELMHES, NUM. MATH. 12, 349-368(1968) BY MARTIN AND WILKINSON.

GIVEN A REAL GENERAL MATRIX, THIS SUBROUTINE REDUCES A SUBMATRIX SITUATED IN ROWS AND COLUMNS LOW THROUGH IGH TO UPPER HESSENBERG FORM BY STABILIZED ELEMENTARY SIMILARITY TRANSFORMATIONS.

ON INPUT

NM MUST BE SET TO THE ROW DIMENSION OF TWO-DIMENSIONAL ARRAY PARAMETERS AS DECLARED IN THE CALLING PROGRAM DIMENSION STATEMENT.

N IS THE ORDER OF THE MATRIX.

LOW AND IGH ARE INTEGERS DETERMINED BY THE BALANCING SUBROUTINE BALANC. IF BALANC HAS NOT BEEN USED, SET LOW=1, IGH=N.

A CONTAINS THE INPUT MATRIX.

ON OUTPUT

A CONTAINS THE HESSENBERG MATRIX. THE MULTIPLIERS WHICH WERE USED IN THE REDUCTION ARE STORED IN THE REMAINING TRIANGLE UNDER THE HESSENBERG MATRIX.

RINDEX CONTAINS INFORMATION ON THE ROWS AND COLUMNS INTERCHANGED IN THE REDUCTION.
ONLY ELEMENTS LOW THROUGH IGH ARE USED.

QUESTIONS AND COMMENTS SHOULD BE DIRECTED TO BURTON S. GARROW, MATHEMATICS AND COMPUTER SCIENCE DIV, ARGONNE NATIONAL LABORATORY

13. ABSTRACT (Maximum 200 words)
The popular QR algorithm for solving all eigenvalues of an unsymmetric matrix is reviewed. Among the basic components in the QR algorithm, it has been concluded from this study, that the reduction of an unsymmetric matrix to a Hessenberg form (before applying the QR algorithm itself) can be done effectively by exploiting the vector speed and multiple processors offered by modern high-performance computers.

Numerical examples of several test cases have indicated that the proposed parallel-vector algorithm for converting a given unsymmetric matrix to a Hessenberg form offers computational advantages over the existing algorithm. The time saving obtained by the proposed methods is increased as the problem size increased.

NASA Contractor Report 191417
Parallel-Vector Unsymmetric Eigen-Solver on High Performance Computers
Duc T. Nguyen and Qin Jiangning
February 1993

The word "Unsymmetric" in the title on the cover should be "Unsymmetric." Task 122 has been added to the contract number on the cover.

A corrected cover is attached.
