NASA's Office of Aeronautics and Space Technology (OAST) conducted a workshop on technology for space station evolution on 16-19 Jan. 1990. The purpose of this workshop was to collect and clarify Space Station Freedom technology requirements for evolution and to describe technologies that can potentially fill those requirements. These proceedings are organized into an Executive Summary and Overview and five volumes containing the Technology Discipline Presentations. Volume 4 consists of the technology discipline sections for Power, Propulsion, and Robotics. For each technology discipline, there is a Level 3 subsystem description, along with the papers. For individual titles, see N93-27804 through N93-27824.
Space Station *Freedom*, now under development, is a manned low Earth orbit facility which will become part of the space infrastructure. Starting in the mid 1990s, *Freedom* will support a wide range of activities, including scientific research, technology development, commercial ventures and, eventually, serve as a transportation node for space exploration. While the initial facility will not be capable of meeting all requirements, the space station will evolve over time as requirements and on-board activities mature and change. The space station design, therefore, allows for evolution to:

- expand capability,
- increase efficiency, and
- add new functions.

It is anticipated that many of the evolutionary changes will be accomplished through on-orbit replacement of systems, subsystems, and components as technology advances. Therefore, technology development is critical to ensure the continuing operation and expansion of the facility.

The Office of Aeronautics, Exploration and Technology (OAET) has sponsored development of many of the technologies that are now part of Space Station *Freedom*’s baseline design. Evolutionary and operational aspects of *Freedom* continue to be an important thrust of OAET’s Research and Technology (R&T) efforts.

This workshop has been an important step in our understanding of the space station’s baseline systems, the evolutionary scenarios including the station’s role in space exploration, and the technologies that will be necessary to meet evolutionary and growth requirements.

It is anticipated that application of the information acquired through the workshop will lead to further technology development efforts to benefit *Freedom* and will lead to continued collaboration between the Space Station *Freedom* Program and the technology development community.

Arnold D. Aldrich
Associate Administrator for Aeronautics, Exploration and Technology
CLARIFICATION

Since the workshop was conducted in January of 1990, there have been some organizational changes throughout the agency. The Office of Aeronautics and Space Technology (OAST) has been reorganized to include the former Office of Exploration and is now called the Office of Aeronautics, Exploration, and Technology (OAET). Also, the Human Exploration Initiative (HEI) has been expanded and renamed the Space Exploration Initiative (SEI). Some of the materials in these proceedings were prepared after the workshop, and, therefore, references to new organizational entities and new programs may be found in certain sections.

Computer Services AI Center
Space Teleoperations Technology for Space Station Evolution 463-18
- Gerald J. Reuter, JSC
Twenty Year Forecast of NASA Robotics Requirements for Space Exploration - Del Tesar, University of Texas, Austin 477-19
Telerobotics Capabilities for Space Station Operations - David Akin, MIT 479-19
FTS Evolution - David Provost, GSFC 481-19
INTRODUCTION

NASA's Office of Aeronautics and Space Technology (OAST) conducted a workshop on technology for space station evolution January 16-19, 1990, in Dallas, Texas. The purpose of this workshop was to collect and clarify Space Station Freedom technology requirements for evolution and to describe technologies that can potentially fill those requirements. OAST will use the output of the workshop as input for planning a technology program to serve the needs of space station evolution. The main product of the workshop is a set of program plans and descriptions for individual technology areas. These plans are the cumulative recommendations of the more than 300 participants, which included researchers, technologists, and managers from aerospace industries, universities, and government organizations.

The identification of the technology areas to be included, as well as the development of the program plans, was initiated by assigning NASA chairmen to the eleven technology disciplines under consideration. The disciplines are as follows:

- Attitude Control and Stabilization (ACS)
- Communications and Tracking (C&T)
- Data Management System (DMS)
- Environmental Control and Life Support Systems (ECLSS)
- Extravehicular Activity/Manned Systems (EVA/MANSYS)
- Fluid Management System (FMS)
- Power System (POWER)
- Propulsion (PROP)
- Robotics (ROBOTICS)
- Structures/Materials (STRUCT)
- Thermal Control System (THERM)

Each chairman worked with a panel of experts involved in research and development in the particular discipline. The chairmen, with the assistance of their panels, were responsible for selecting invited presentations, identifying and inviting Space Station Freedom Level III subsystem managers, and focusing the discussion of the participants. In each discipline session, presentations describing status of the current programs were made by the Level III subsystem managers and by OAST program managers. After invited presentations by leading industry, university, and NASA researchers, the sessions were devoted to identifying technology requirements and to planning programs for development of the identified technology areas. Particular attention was given to the potential requirements of the Human Exploration Initiative (HEI). The combined inputs of the participants in each session were incorporated into a package including an
overall discipline summary, recommendations and issues, and proposed development plans for specific technology areas within the discipline. These technology discipline summary packages were later supplemented by the chairmen and their panels to include the impact of varied funding levels on the maturity of the selected technologies. OAST will review the program plans and recommended funding levels based on available funding and overall NASA priorities and incorporate them into a new OAST initiative advocacy package for space station evolution technology.

These proceedings are organized into an Executive Summary and Overview and five volumes containing the Technology Discipline Presentations.

Volume IV consists of the technology discipline sections for Power, Propulsion, and Robotics. For each technology discipline in this volume, there is a Level 3 subsystem description, along with the invited papers for that discipline.

SPACE STATION FREEDOM

Electrical Power System

WP–04

Donald L. Nored
NASA – LeRC
January 16, 1990
Key EPS Technical Requirements

- **Performance**
  - 75 kW at AC (100 kW Peak)
  - 37.5 kW at PMC (50 kW Peak)
  - Growth to 175 kW (215 kW Peak)

- **Mass**
  - 94,586 lb (total launch mass)

- **Assembly sequence**
  - NSTS compatibility
  - MB-1, MB-6, MB-11 assembly sequence
  - Active station / evaluate passive options

- **Reliability**
  - Failure tolerance requirements
  - System availability requirements

- **Maintainability**
  - 30-yr. life through ORU replacement
  - EVA & IVA allocations (54 & 100 hr/yr)
  - Resupply mass allocation (TBD lb/yr)

- **Environment**
  - Low earth orbit (180–240 miles)
  - NSTS launch vehicle environment
Rephasing Impacts

- PMAD distribution changed from AC to DC
  + Lowest initial costs
  + Heavier system
  + Channelized system does not grow gracefully
  + Risk is probably about the same
  + Switchgear area of concern

- Polar platform hardware/software deleted

- Solar Dynamic “PGS” test eliminated
  + Hooks and scars plus key development tests retained
  + Viable program still in place
  + Growth here is inevitable
PHASE I EPS DELIVERABLES

Space Station (75 kW)

Power Management and Distribution (PMAD) System
- EPS End to End Architecture
- Power Conversion and Distribution Equipment
- Power System Control Hardware and Software
- Common switchgear for Secondary Distribution

Photovoltaic Power Module (4) (18.75 kW)
- Photovoltaic Power Generation
- Electrochemical Energy Storage
- Power Conversion and Control Equipment
- Beta Gimbals
- Thermal Control

Solar Dynamic Definition
- Preliminary Design for Hooks and Scarfs
- Supporting Development for Concentrator & Receiver

BLANKET CONTAINMENT BOX AND BOX POSITIONING SUBASSEMBLIES

- BLANKET COVER AND CONTAINER LATCHED TOGETHER FORMING CONTAINMENT BOX FOR RETRACTED BLANKET
- BOX STRUCTURALLY SUPPORTS BLANKET DURING LAUNCH
- FABRICATED FROM ALUMINUM AND ALUMINUM HONEYCOMB MATERIALS
- FOAM PADDING INTERFACES WITH FOLDED BLANKET STACK AT BASE AND COVER
- GUIDE WIRES RUN THROUGH GROMMETS ALONG BACK OF BLANKET PANELS
- CONTROL BLANKET POSITIONING DURING EXTENSION AND RETRACTION
- BLANKETS ARE RETRACTED FOR ORU REPLACEMENT
**SOLAR CELL**

- **SILICON CELL**
  - 200 µm (0.008 in.) THICK
  - 8 X 8 cm (3.15 X 3.15 in) SQUARE

- **COVER SLIDE**
  - 150 µm THICK
  - CERIA DOPED (CMX) GLASS

- **DOW CORNING DC93-500 ADHESIVE**

- **PANEL SUBSTRATE CIRCUIT WELDED TO CELL BACKSURFACE THROUGH OVERLAY PUNCHED HOLES**

- **AVERAGE CELL TEMPERATURE DURING OPERATION**
  - 50 DEGREES C FOR STATION

**EXPLoded VIEW OF ARRAY AND CELL SUBSTRATE**
BYPASS DIODE ASSEMBLY

THE BYPASS DIODE IS A CIRCUIT PROTECTION DEVICE THAT:
- MINIMIZES PERFORMANCE IMPACT OF FRACTURED OR OPEN CIRCUIT CELLS
- ELIMINATES POTENTIAL CELL DAMAGE DUE TO REVERSE BIAS HEATUP DURING SHADOWING

ONE DIODE IS ELECTRICALLY CONNECTED IN PARALLEL WITH EVERY EIGHT SOLAR CELL ASSEMBLIES

DIODES WILL CONSIST OF EITHER GERMANIUM, SILICON SHOTTKY, OR PLANAR SILICON DIES SANDWICHED IN A HOUSING THAT CONTAINS LOCATIONS FOR ATTACHMENT TO THE PRINTED CIRCUIT

LARGE AREA REQUIRED FOR HEAT DISSIPATION

THIN DIODE REQUIRED TO PREVENT EXCESSIVE STACK HEIGHT BUILDUP IN THE STOWED BLANKET

EXPANDED VIEW OF BYPASS DIODE (DIMENSIONS IN INCHES)

WEIGHT: 73.5 gm
KAPTON WITH ATOMIC OXYGEN RESISTANT COATING

DESCRIPTION

• 1 mil KAPTON H POLYAMIDE FILM
• 1300 Å RF SPUTTERED SiO$_x$ COATING ON BOTH SIDES

PROPERTIES COMPATIBLE WITH SOLAR ARRAY FLEXIBLE CIRCUIT DESIGN

• PROVIDES REQUIRED EMITTANCE AND ABSORPTANCE
• PROVIDES GOOD BONDING SURFACE FOR COPPER INTERCONNECTS
• RESISTS FLEXIBLE CIRCUIT FABRICATION PROCESSING
• PROVIDES SPACE VACUUM STABILITY
• RESISTS ATOMIC OXYGEN DEGRADATION
SOLAR ARRAY DESIGN BENEFITS

- Minimum weight (fewer STS launches)
- Transparent blanket yields higher array efficiency
- Deployment/retraction concept minimized IVA/EVA time and reduces cost
  - Demonstrated with OAST-1 flight experiment (STS 41-D)
- Large areas silicon cells minimize costs and increase reliability
  - Reduced number of cells and interconnects
  - Reduced array area/weight
**SEQUENTIAL SHUNT UNIT**

- Provides efficient method for
- Matching array power to load demand
- Regulating array output voltage
- One SSU per wing
- Mounted to array mast canister
- Large faces of box radiate SSU waste heat directly to space
- Box faces have required thermal mass to control Sun/eclipse temperature excursions
- Automatically maintains voltage below safe max of 200V
- Precludes cold-array overvoltage at eclipse emergence
- Can be commanded by PV controller (PVC) to shunt all array power for array maintenance

**SEQUENTIAL SHUNT UNIT (SSU)**

PMAD System Responsibilities

Design end-to-end Power System Architecture

Design, Develop, Produce PMAD Hardware for Station

- **Hardware responsibilities include:**
  - DC/DC Converters
  - PV Controller
  - Cabling/Connectors/Switchgear for Primary Distribution
  - Common RPC Modules for Secondary and Tertiary Distribution

- **Software responsibilities include:**
  - Condition Monitoring and Controls
  - Energy Management
  - Fault Tolerance and Redundancy Management
  - PMAD Modeling and Simulation

End-to-End PMAD System Verification and ORU/Component Verification

EPS Specifications and Standards

Deliver PMAD Hardware to Element Owners and Support Integration
Key Power Requirements - AC

- **Power:**

  - **User:** 75 kW-A/100 kW-P
  - **Habitat Module:** 25 kW peak
  - **Laboratory Module:** 25 kW peak
  - **Nodes:** 12.5 kW peak
  - **ESA:** 25 kW peak
  - **JEM:** 25 kW peak
  - **APAE & MSC:** (TBD) (10 kW)
  - **Pressurized Payload:** (TBD) (12 kW)
  - **Cables:** Sized and installed to deliver peak power
  - **Growth:** 175 kW-A/215 kW-P
  - **Grounding:** Single point (designed negative)
Key Features of PMC and AC Architecture

PMC Station:
- 37.5 kW average 50 kW peak
- PMAD is divided into four DC channels each producing 9.4 kW average
- DC channel size is limited by the ability of DC switches to break fault current
- 9.4 kW channels produce 300–400 A fault currents which can be broken with existing DC switch technology
- Small channel size limits user flexibility; loads must be timelined so total is less than 9.4 kW per channel

AC Station:
- 75 kW average/100 kW peak
- Four DC channels each producing 18.75 kW average
- Improved user flexibility
- Requires high power (600–800A) DC switch
POWER SYSTEM ARCHITECTURE
AC CONFIGURATION
DDCU & MBSU External Interface

Rocketdyne

- Electrical connectors for power & data
- 2 guide pins for mechanical attachment
- EVA & robotic installation & replacement
- Fin heat exchanger thermal interface
- Coldplate temperature ≤ 50°F

Host Element

Electrical Connectors
Attachment Pin
Thermal Interfacing Radiator Fins
Electrical Connectors
Attachment Pin
Coldplate Fins
Mounting Structure Coldplate (50°F)
Common RPC Modules for Secondary and Tertiary Distribution

RPC Module Features:
- An RPC is a remote controlled switch
- An RPC module is an ORU box containing one or more RPC's
- Four RPC module types have been identified:
  1 x 130 Amp
  2 x 50 Amp
  4 x 25 Amp
  8 x 10 Amp
- All modules have same outline and mounting
- All modules have same input connector
- All modules have same output connector shell; pin configuration unique to module type
**RPC Module**

- Wedge provides the necessary contact pressure between RPC base & coldplate to conduct heat away.
- J1 & J2 are electrical inputs. J3 is output.

**Four RPC Types:**
- 8-channel output, 10 A/channel
- 4-channel output, 25 A/channel
- 2-channel output, 50 A/channel
- 1-channel output, 130 A

**Same overall dimensions for each type RPC. Only connector pinout configuration would differ.**
Electric Power System Control Hierarchy (Rephase)

- **Power Management Controller**
  - DMS/PMAD interface, load management configuration control, system analysis

- **Photovoltaic Controller**
  - Array regulation, battery charge/discharge control, beta gimbal control, outboard power distribution control, PV thermal control

- **MBSU Controller**
  - Primary distribution monitoring and control, DC-DC converter control
PMAD Controls Implementation

- **Software Implemented**
  - Sensor validation (detection of soft faults)
  - Contingency readiness - reconfiguration/load shed preplanning model
  - Status data to DMS/OMS/crew/ground
  - Manual override - via DMS command
  - GN&C data from DMS
  - Fault detection isolation & recovery/Redundancy management (FDIR/RM)
  - Startup-shutdown
  - Pointing and tracking
  - Battery charge/discharge
  - PV module thermal control
PMAD Controls Implementation

- **Hardware Implemented**
  - Basic overload protection (RPC)
  - Hard fault (line) protection (RBI)
  - Voltage regulation
  - Array control
PMC Control Architecture Design

- Two PMCU's (1 SDP = 1 PMCU), one active, one in cold standby
- Two Bus Controllers / Monitor Interfaces (MIL-STD-1553B) in each SDP:
  - Meets fault tolerance requirements with reduced hardware
- Two Hot PVCUs on each PV IEA
  - Supports failure of 1 PVC with no loss of PV control
- PVCU to MBSU Communication
  - Required for two fault tolerance given only two SDPs and no Tier II peer-to-peer communication
## PMAD Systems Fault - Tolerant Features

Major Design Drivers

- Design requirements
  - Power output & quality
  - Environment (launch & on-orbit)
  - Thermal control
  - Loads & dynamics
  - Electrical isolation & grounding
  - Growth capability
  - Producibility & testability

- Integration requirements
  - System integration (architecture & interfaces)
  - NSTS Integration
  - Flight by flight partitioning (including mass)
  - On-orbit assembly
  - User accommodation
  - Commonality

- Operational requirements
  - Reliability, availability & failure tolerance
  - Maintainability
  - Safety
  - Operability
  - Supportability (including resupply mass & drag)
  - Automation & robotics

- Cost (Initial & life cycle)

BRIEFING AGENDA

• Prime Contract Activity

• Advanced Development
  - Heat receiver
  - Concentrator
25-kWe Net CBC Power Module Configuration

- Heat Rejection Assembly
  - 8 Pumped Coolant Radiant Panels
  - 26.4 ft x 7.5 ft Each
  - Radiant Area = 3168 ft²
  - Total Length = 70.2 ft
  - Total Width = 27.6 ft

- Constructible Concentrator Assembly
  - 19 Hex Truss Panels
  - Effective Diameter = 47.2 ft
  - Effective Aperture 1751 ft²

- PV Module Interface
- Cable Trays
- Integration Hardware Assembly (GFE)
- Transverse Boom Truss Bays
- Radiator Base Structure
- Beta Gimbal Assembly (PFE)
- Interface Structure Assembly
- Power Conversion Unit Assembly
  - Recuperated-Brayton-Cycle
  - Helium/Xenon Working Fluid

- Vernier Pointing Gimbal
- Receiver Assembly
  - LIF-CaF₂ Eutectic Salt
  - Thermal Storage
  - Direct Insulation
  - Integral He-Xe Heater
  - Length = 118 in.
  - Diameter = 85 in.

- Electrical Equipment Assembly (PFE)

SOLAR DYNAMICS PRIME CONTRACT ACTIVITY

• Solar Dynamic Power Module preliminary design
  • Prepare design to define hardware configuration (sizes and mass). Conduct trade studies (structural/dynamic analyses, materials selection, operational procedures). Develop top level drawings.
  • Provide credible knowledge of Solar Dynamic Power Module to perform "Hooks and Scars" activities

• "Hooks and Scars"
  • Define assembly, operational and physical/functional interfaces imposed by the SD module
  • Provide requirements to Non-SD elements/systems to ensure that SD power can be added

• Solar Dynamic Component Development Tests
  • Concentrator (coupons, full-size facets, face up/face down)
  • Receiver (canisters, single tube test, full-size element)
  • Radiator (Hypervelocity, AO, UV, etc)
  • Integration (FP & T and receiver/concentrator interface)
Key Solar Dynamic Power Module Requirements

- Provide minimum of 28-kWe NET to inboard PV Module throughout any orbit at any time of year within prescribed orbit altitude envelope (after distribution via PMAD, provides 25-kWe at user interface)
- Provide peaking power of 32.2-kWe NET to inboard PV Module for up to 7.5 minutes during both sun and shade portions of the orbit (maximum of 15 minutes total peaking per orbit)
- Be capable of automatic startup, shutdown, and continuous operation throughout load changes, peaking, turndown, and load shedding
- Shall not produce dynamic instabilities
- Maximize the use of common hardware, software, and standard interfaces
- Be capable of long term operation by means of ORU replacement

ADVANCED DEVELOPMENT

- Heat Receiver (NAS3-24669) - Boeing
- Concentrator (NAS3-24670) - Harris
SOLAR DYNAMIC HEAT RECEIVER TECHNOLOGY

- **Purpose**
  - Address Key Technical Issues Associated With Heat Receiver
  - Provide Database to Support Detail Design
  - Demonstration Testing

- **Background**
  - NAS3-24669 Awarded to Boeing in October 1985

- **Project Objectives**
  - Identify and Resolve Technical Issues Associated With 25 kWe CBC Heat Receiver
  - Develop and Validate Analytical Methods
  - Fabricate, Test and Evaluate 25 kWe CBC Heat Receiver

- **Key Design Considerations**
  - Material Selection
  - TES Performance in Micro-Gravity
  - TES Compatibility With Containment Materials
  - Thermal Expansion
  - Fabricability
  - Sea Level Test In Vacuum

- **Tasks**
  - Conceptual Designs and Trade Studies
  - Preliminary/Detail Design
  - Fabrication, Test and Delivery
1. Thermal conductivity enhancement
2. Void distribution control

SOLAR DYNAMIC HEAT RECEIVER TECHNOLOGY

KEY REQUIREMENTS/FEATURES

REQUIREMENTS

- Power 102 kwt (25 kwe CBC)
- Temperature 900°F Inlet; 1300°F Exit
- Inlet Pressure 92 psia
- Working Fluid - Helium - Xenon (MW 40)

FEATURES

- GEOMETRY - Diameter - 70 In.
  Length - 80 In.
  Aperture Dia. 13 In.

- TUBING - Fluid Tube - 2 In. OD + 0.06 In. Wall
  TES Tube - 3.94 In. OD, 3.60 In. ID, 0.01 In. Wall
  Convolution Pitch - 0.25 In.

- Materials - TES Salt - 21% LiF - 79% CaF
  Fluid Tube & TES Containment - Inconel 617
  Felt Metal - Nickel
  Other - CRES
SOLAR DYNAMIC HEAT RECEIVER TECHNOLOGY

SIGNIFICANT EVENTS

• Felt Metal Concept Demonstrated
  • Thermal Conductivity Enhancement
  • Symmetrical Salt Distribution
  • 2500 Hours Thermal Cycling
  • 5000 Hours Materials Compatibility - Inconel 617 & LiF-CaF₂
• TES Containment Closure Welds Validated
  • Laser Weld of Bellows to End-Cap
  • Electron-Beam Weld of PCM Fill Tube
• Full-Size, 6-Tube Molten Salt Fill Demonstrated
• Receiver Fabrication Complete May 1990
• Thermal Vacuum Testing Complete August 1990
SOLAR CONCENTRATOR ADVANCED DEVELOPMENT

- Purpose
  - Address Key Technical Issues Associated With Concentrator
  - Detail Design Support
  - Demonstration Testing

- Background
  - NAS3-24670 Awarded to Harris Corp. in November 1988

- Project Objectives
  - Select Design, Fabricate and Test a Viable Concentrator for SSF

- Key Design Considerations
  - Material Selection (Environmental Protection)
  - Aiming Errors
  - Facet Alignment
  - Fabricability
  - Reflectance
  - Structural Repeatability

- Tasks
  - Conceptual Design & Trade Studies
  - Preliminary/Detail Design
  - Fabrication, Test & Delivery

Rockwell International
Rocketsdyne Division
SOLAR CONCENTRATOR

KEY REQUIREMENTS/FEATURES

- **Requirements**
  - Deliver 188 kw of Thermal Energy to the Receiver
  - Pointing Accuracy: \( \pm 0.1^\circ \) (1 \( \sigma \))
  - Specular Reflectance: >0.88
  - Slope Error: \( \pm 2.25 \text{ mr (half cone angle)} \)
  - Design Lifetime: 15 years

- **Features**
  - 19 Hexagonal Panel (456 facets)
  - Toroidal Facet Curvature
  - Parabolic Mapping
  - \(<2\text{ lb. per facet}\)
  - SiO\textsubscript{2} Protected, Silver Reflective Surface on Graphite Epoxy with Al Honeycomb
SOLAR CONCENTRATOR ADVANCED DEVELOPMENT

SIGNIFICANT EVENTS

- Refined Design With Significant Commonality of Components
- Demonstrated Fabrication and Panel Structural Test Techniques
- Improved Box Beam Construction Technique
- Refined Facet Optical Specifications and Capabilities
- Demonstrated Seven Panel Assembly/Structural Repeatability
- Developed Fabrication Methods for Facets Having A Vapor Deposited Reflective Surface
- Delivered to NASA Three Vapor Deposited Reflective Surface Facets that had Measured Slope Errors Less Than 1.5 mrad
- Demonstrated Nineteen Panel Assembly/Structural Repeatability
Accomplishments In SD Development

- **Module Integration**
  - Initial release for Hooks and Scars document prepared
  - Fine pointing and tracking concept prepared for elevation axis
  - Four launch package options defined & prioritized
  - SD impact on GN&C in terms of aerodynamics, gyroscopic, & gravity gradient torques found to be minimal
  - Initial module assembly procedure defined

- **Concentrator**
  - Latch guide designed, reviewed, and placed in fabrication for LeRC NBF test (coordinated with JSC Crew & Thermal Sys. Div.)
  - NBF hardware fabrication
  - Silver-coated, high temperature facet samples produced and met requirements
  - Aluminum coated, high temperature full-size facets produced
  - Completed design, fabrication, and testing (optics and repeatability) of 19-Panel solar concentrator (SCAD)
Accomplishments In SD Development
(Continued)

- Receiver
  - Single canister and breadpan tests show no significant corrosion between Haynes 188 and Salt (> 14,000 Hrs)
  - Single-tube test has verified receiver heat transfer element performance

- Power Conversion Unit
  - Engine startup power requirement calculated
  - 15kW BRU refurbished and in test at LeRC

- Radiator Assembly
  - Hypervelocity test conducted at JSC
  - Hypervelocity test articles fabricated for future test at JSC
ADVANCED SOLAR DYNAMIC TECHNOLOGY PROGRAM

PRESENTATION FOR

"TECHNOLOGY FOR SPACE STATION EVOLUTION - A WORKSHOP"

JANUARY 16-19, 1990

BY

JAMES CALOGERAS
NASA LEWIS RESEARCH CENTER
SOLAR DYNAMICS AND THERMAL SYSTEMS BRANCH
ADVANCED SOLAR DYNAMIC TECHNOLOGY PROGRAM

• MISSIONS AND SYSTEMS ANALYSIS
  - DETERMINE SD POWER SYSTEMS REQUIREMENTS
  - CRITICAL TECHNOLOGIES WHERE ADVANCEMENT LEADS TO LARGE PAYOFF

• ADVANCED CONCENTRATORS
  - MORE EFFICIENT (HIGHER CONCENTRATOR RATIOS)
  - AUTO DEPLOYABLE (WITHOUT ASTRONAUT ASSISTANCE)
  - LONGER SERVICE LIFE

• ADVANCED CONCENTRATORS
  - LIGHTER WEIGHT
  - MORE EFFICIENT
  - SMALLER

• MICROGRAVITY EFFECTS
  THE LOW G FIELD ON ORBIT HAS A SIGNIFICANT EFFECT ON THE VOIDS THAT FORM IN THE HEAT STORAGE MATERIAL. RESEARCH IN LOW G ENVIRONMENTS IS BEING CONDUCTED TO LEARN HOW TO AVOID THE PROBLEMS WITH VOID FORMATION AND MIGRATION.
ADVANCED SOLAR DYNAMIC TECHNOLOGY PROGRAM

• SPACECRAFT ENVIRONMENT
  VARIOUS ORBITS HAVE ELEMENTS, SUCH AS AO, UV, CHARGED PARTICLES, ETC., THAT ATTACK VARIOUS MATERIALS, THEREBY SHORTENING THEIR SERVICE LIFE. AN ONGOING EFFORT IS BEING CONDUCTED TO IDENTIFY THOSE MATERIALS THAT ARE IMMUNE TO THE ENVIRONMENT OR METHODS TO PROTECT THOSE MATERIALS THAT ARE.

• POWER CONVERSION SUBSYSTEM
  TWO HEAT ENGINE CONCEPTS ARE THE PRIME CANDIDATES FOR CONVERTING THE FOCUSED SUNLIGHT INTO ELECTRICAL ENERGY:

  - STIRLING ENGINE (This engine is under development by another Branch within the Power Technology Division)

  - BRAYTON ENGINE (The technology of this engine is mature)

• RADIATORS
  ADVANCED RADIATORS FOR SPACE ARE BEING DEVELOPED FOR CSTI HIGH CAPACITY POWER.

ADVANCED SOLAR DYNAMIC TECHNOLOGY PROGRAM

GOALS

SPECIFIC POWER

The electric power output per unit mass of the total power system is an important figure of merit that impacts the launch weights and costs. To lower these, both the mass and efficiency of the SD system and the components of that system need to be reduced.

REDUCTION OF HEAT RECEIVER MASS

Since HR weight is the largest fraction of the overall SD system weight, its reduction is a prime goal of our activities.

REDUCTION OF CONCENTRATOR MASS

With present technology, the concentrator specific mass (including the supporting structure) is more than double the goal shown. Results to date suggest that this goal is achievable, even for auto deployable concentrators.

CONCENTRATOR RATIO

The overall SD system efficiency is in large part affected by the ability of the concentrator to reflect as much of the incoming sunlight as possible (high reflectivity) and focus it into the smallest possible diameter (concentrator ratio). To achieve a high concentrator efficiency, the dished surface must conform very closely to a perfect parabolic surface (to within a slope error less than 1.0 milliradian) and must have a very smooth surface (less than 50 to 100 angstroms) with a highly reflective layer (silver or aluminum).

REDUCTION OF RADIATOR MASS

The Stirling and Brayton engines operate more efficiently at high ratios of the inlet temperature to outlet temperature. The lower the outlet temperature, the larger is the radiator area required to reject heat. (The radiator area increases as the fourth power of the outlet temperature). Large efficient radiators will require the use of heat pipes and very light weight design.
ADVANCED SOLAR DYNAMIC TECHNOLOGY PROGRAM

GOALS

SPECIFIC POWER

20-25 W/kg

REDUCTION OF HEAT RECEIVER MASS TO

20-33 kg/kWe

REDUCTION OF CONCENTRATOR MASS TO

1-2 kg/M^2

CONCENTRATION RATIO

2000-5000

REDUCTION OF RADIATOR MASS TO

4-5 kg/M^2

(HEAT PIPE)
ADVANCED SOLAR DYNAMIC TECHNOLOGY PROGRAM

TECHNOLOGY APPROACH

ADVANCED CONCENTRATORS

TO MEET THE GOALS OF LIGHT WEIGHT, HIGH EFFICIENCY, LONG SERVICE LIFE, AND AUTO DEPLOY ABILITY, ACTIVITIES ARE UNDERWAY TO:

- DEVELOP METHODS FOR INCREASING THE SURFACE CONTOUR ACCURACY, THE SURFACE SMOOTHNESS AND REFLECTIVITY.

- DEVELOP THE FABRICATION TECHNIQUES REQUIRED FOR EFFICIENT CONCENTRATORS.

- IDENTIFY SPACE COMPATIBLE MATERIAL THAT WILL RESIST THE SPACE HAZARDS AND RETAIN THE DIMENSIONAL STABILITY NEEDED FOR HIGH EFFICIENCY AND LONG LIFE.

- IDENTIFY CONCENTRATOR CONCEPTS THAT CAN BE PACKAGED INTO A SMALL VOLUME FOR LAUNCHING AND THAT ARE AUTO DEPLOYABLE ON ORBIT.
ADVANCED SOLAR DYNAMIC TECHNOLOGY PROGRAM

- ADVANCED HEAT RECEIVERS
  - TES VOID-MICROGRAVITY. ITS UNDERSTANDING IS KEY TO THE SUCCESSFUL OPERATION OF A SALT TES SYSTEM (CURRENT STATE-OF-THE-ART). EFFORTS INCLUDE BOTH ANALYTICAL AND EXPERIMENTAL ACTIVITIES TOWARD A TECHNICAL UNDERSTANDING OF THE PHENOMENON OF VOID BEHAVIOR UNDER MICROGRAVITY.

- POWER CONVERSION SYSTEMS
  - A MAJOR EFFORT IS IN PROGRESS AT NASA-LEWIS TO DEVELOP LIGHT WEIGHT, HIGH EFFICIENCY STIRLING ENGINE FOR USE IN SD SYSTEMS. NO WORK IS BEING DONE INSIDE NASA TO IMPROVE THE BRAYTON ENGINE; HOWEVER, DOD IS SUPPORTING BRAYTON R & D.

- INCREASE CONFIDENCE - - - - - - -
  - TECHNOLOGY VERIFICATION GROUND EXPERIMENTS ARE PLANNED FOR THE MAJOR COMPONENTS OF AN SD POWER SYSTEM.
ADVANCED SOLAR DYNAMIC TECHNOLOGY PROGRAM

TECHNOLOGY APPROACH

- ADVANCED HEAT RECEIVERS

THE TECHNICAL APPROACH TO ADVANCED RECEIVERS IS THE INCORPORATION OF DESIGNS AND THE DEVELOPMENT OF MATERIALS DIRECTED AT SMALLER, LIGHT WEIGHT, AND MORE DURABLE RECEIVERS.

- BULK TES VOLUME (AS OPPOSED TO SMALL ELEMENTS) LESSENS THE NEED FOR STRUCTURAL SUPPORT STRUCTURE AND REDUCES RECEIVER MASS. EFFORTS ARE BEING DIRECTED TO INCREASE THIS VOLUME WITHOUT SACRIFICING ITS STORAGE PERFORMANCE OR IMPOSING STRUCTURAL STRESS.

- TES WITH HIGH THERMAL CONDUCTIVITY, HEAT OF FUSION AND DENSITY SHRINKS THE VOLUME OCCUPIED WITH THE STORAGE MATERIAL AND DECREASES THE TEMPERATURE DIFFERENCE WITHIN THE TES MATERIAL. TES MATERIALS ARE BEING INVESTIGATED THAT HAVE THESE PROPERTIES WITHOUT DETRIMENTAL EFFECTS SUCH AS CORROSION.

- CAVITY HEAT PIPE DESIGNS IN EFFECT Distribute THE INCOMING SOLAR FLUX THROUGHOUT THE INTERIOR RECEIVER SURFACE AT A CONSTANT TEMPERATURE. THIS FEATURE WOULD CONTRIBUTE TO EXTENDING LIFE OF THE RECEIVER STRUCTURE. THE EFFORT IS TO DESIGN SUCH HEAT PIPES WITHIN THE CONSTRAINTS OF RECEIVER DESIGNS AS DESCRIBED ABOVE.
ADVANCED SOLAR DYNAMIC TECHNOLOGY PROGRAM

TECHNOLOGY APPROACH

- ADVANCED CONCENTRATORS
  - HIGH EFFICIENCY/ACCURACY (.5-1.50 MRAD)
  - NEW FABRICATION TECHNIQUES
  - MATERIALS SPACE COMPATIBILITY
  - DEPLOYMENT TECHNIQUES

- ADVANCED HEAT RECEIVERS
  - BULK TES VOLUME (AS OPPOSED TO SMALL ELEMENTS)
  - TES WITH HIGH THERMAL CONDUCTIVITY & DENSITY
  - CAVALITY HEAT PIPE DESIGNS
  - TES VOID - MICROGRAVITY

- POWER CONVERSION SYSTEMS
  - INCREASED EFFICIENCY THROUGH TECHNOLOGY DEVELOPMENT

  1) STIRLING - MAJOR EFFORT CARRIED OUT BY LeRC STIRLING BRANCH
  2) BRAYTON - CARRIED OUT OUTSIDE OF NASA

- INCREASE CONFIDENCE IN RELIABILITY & PERFORMANCE OF CONCENTRATOR, RECEIVER, PCS, AND RADIATOR
  - TECHNOLOGY VERIFICATION/VALIDATION

  1) EXPERIMENTS & ANALYSIS
ADVANCED SPACE CONCENTRATOR DEVELOPMENT

TECHNOLOGY APPROACH

THE APPROACH TO CONCENTRATOR DEVELOPMENT CONSISTS OF TWO PARALLEL EFFORTS:

- IDENTIFYING SUITABLE CONCENTRATOR FOR CONCEPTS
- IDENTIFYING SUITABLE REFLECTOR CONCEPTS AND MATERIALS FOR THOSE REFLECTORS.

CONCENTRATOR CONCEPTS DEVELOPMENT

THERE ARE BASICALLY TWO TYPES OF CONCENTRATORS:

- THE REFLECTING PARABOLIC DISH TYPE
- THE PARABOLIC DOME SHAPE FRESNELL LENS TYPE.

THE WORK ON ADVANCED AUTO DEPLOYABLE PARABOLIC DISH CONCENTRATORS IS CONTINUING.
ADVANCED SPACE CONCENTRATOR DEVELOPMENT

REFLECTOR CONCEPTS AND MATERIALS

A REFLECTOR CONSISTS OF FIVE DIFFERENT LAYERS:

1. A SUBSTRATE: IT IS THE PRIMARY MINOR STRUCTURE ONTO WHICH THE REFLECTING LAYER IS DEPOSITED. CANDIDATES ARE: HONEYCOMB SANDWICH PANELS, LIGHT WEIGHT FOAM SANDWICH PANELS, THIN METALLIC OR COMPOSITE MEMBRANES.

2. A LEVELING LAYER: USUALLY THE SUBSTRATE, FACE ONTO WHICH THE REFLECTING LAYER IS TO BE DEPOSITED IS NOT SMOOTH ENOUGH TO YIELD A HIGHLY SPECULAR REFLECTING SURFACE. HENCE, THE SUBSTRATE FACE MUST BE SMOOTHED BY POLISHING OR APPLYING A THIN (5 MICRONS TO 0.5mm) SMOOTHING LAYER. CANDIDATE MATERIALS ARE: VERY LOW VISCOSITY/HIGH SURFACE TENSION MONOMERS, POLYMERS, AND OTHER SIMILAR MATERIALS.

3. REFLECTING LAYER: SILVER AND ALUMINUM ARE THE MOST HIGHLY REFLECTIVE MATERIALS, SILVER BEING MORE REFLECTIVE THAN ALUMINUM. SILVER, ON THE OTHER HAND, IS EASILY CORRODED BY TERRESTRIAL CONTAINMENTS SUCH AS, MOISTURE, OXYGEN, AND OTHER GASES, AND BY AO IN LEO. ALUMINUM IS A MUCH MORE RESISTANT MATERIAL BECAUSE OF THE ALUMINUM OXIDE THAT FORMS ON THE SURFACE IN THE PRESENCE OF OXYGEN.

4. THERMAL-PROTECTIVE COATING: USUALLY A TRANSPARENT PROTECTIVE COATING OF SILICON DIOXIDE, ALUMINUM OXIDE, OR BOTH IS PUT ON THE REFLECTIVE LAYER TO PROTECT IT AGAINST DAMAGE BY HANDLING BY AIR BORN GASES AND VAPOERS, AND BY ATOMIC OXYGEN. A TRANSPARENT THERMAL CONTROL COATING MAY BE NEEDED TO ALLOW THE REFLECTOR TO ACHIEVE THE DESIRED OPERATING TEMPERATURE (PREFERABLY ABOVE THE CONDENSATION TEMPERATURE OF SPACE CONTAMINANTS.

5. THERMAL CONTROL COATING ON BACK FORCE: JUST LIKE THE FRONT FACE, THIS COATING IS ALSO USED TO MAINTAIN THE OPERATING RANGE IN THE DESIRED RANGE TO PROTECT THE SUBSTATE FROM ON ORBIT HAZARDS LIKE AO, UV, ETC.
ADVANCED SPACE CONCENTRATOR DEVELOPMENT

**DISHED ALL METAL HONEYCOMB SANDWICH PANELS**
*(FOR SPACE SOLAR CONCENTRATORS)*

These one foot square panels were developed by the Solar Kinetics Inc., Dallas, Texas under a Phase I SBIR contract. The Phase II effort is now in progress. These panels are slightly dished and have a focal length of 20 ft. As shown by the captions in the figure, each panel is a honeycomb sandwich substrate whose face sheet was polished but not over coated with a reflective layer of aluminum or silver.

This photo shows that:

1. The surface contour goal of 1 millirad was met. Note the absence of a warped reflection in any of the panels,

2. The weight goal of 1 to 2 kg/sq. meter is achievable with these substrate panels,

3. An adequately smooth surface may be achievable with the electropolishing polishing method.

**Other Noteworthy Features:**

1. Aluminum & titanium are immune to attack by the space environment,

2. The focal point diameter was about 2 inches diameter.

ADVANCED HEAT RECEIVER DEVELOPMENT

0 ADVANCED RECEIVER TECHNOLOGY VERIFICATION

Two advanced receiver designs are being investigated; one has application for the Stirling engine, the other for Brayton. They both incorporate many common features, e.g. bulk TES storage design, heat pipe operation, with its common concerns on TES containment and on heat pipe operation throughout the heating and cooling cycle. But there are important differences also:

-- The Stirling-Sanders Associates design has a closed receiver volume and the entire cavity surface is covered with wicking. Incoming solar heat is absorbed and transferred by the "dome" to the interior surfaces -- simultaneously to the Stirling engine head and to TES. During shade, the heat absorbed by the TES provides the source to continue heating the engine. The choice of the TES material LiF/CaF₂ was due to the temperature requirements of the Stirling cycle. The technical areas unique to the Stirling design that are to be addressed are the dome design and the wicking system.

-- In the Brayton-Sundstrand Corporation design the cavity is not enclosed by a "dome", but rather by an inner cylindrical receiver wall. The transfer medium is also sodium which transfers heat to the heater tubes. The TES material in this case is LiF which again has been determined by temperature requirements of the Brayton cycle for this application. The critical technical areas for Brayton are the TES container design to minimize the thermal conductivity effects and whether the design will accommodate the TES void when freezing.
o SUPPORTING TECHNOLOGY

-- Advanced TES Materials -- Ge and NiSi

These materials have the highly attractive properties of high density and high thermal conductivity. Virtually the only drawback is their corrosivity to most materials that could be used for containment. Both Oak Ridge and the University of South Florida are investigating candidate container materials.

-- TES/Containment Compatibility

Containment compatibility efforts of fluoride salts and their eutectics are being undertaken at NASA-Lewis in the Materials Division through long term exposure experiments.

-- Thermal Conductivity Enhancement

Another in-house effort, this under the Electro-Physics Branch, is investigating methods to increase TES thermal conductivity. Corrosion-resistant graphite fibers constitute one avenue of research.

-- Analytical Support

The University of South Florida and the Oak Ridge National Laboratory are both developing analytical codes to describe the effects of TES materials as they change phase. South Florida’s effort is directed toward evaluating those parameters affecting the temperature variation of the engine working fluid as the TES material changes phase. ORNL looks at the basic mechanisms governing void behavior under microgravity and is entitled "NASA Oak Ridge Void Experiment" or NORVEX.

-- Space Flight Experiment (TEST)

No extended flight data is available for materials undergoing melting and freezing in microgravity. The TES flight experiment will be the first attempt to obtain such data. Such data will include thermal data and visual information on the void and will provide a basis for verification of the NORVEX code.

Stirling Cavity Heat Pipe (CHP) Receiver

Sanders Associates, A Lockheed Company - Nashua, NH

The operation of the CHP receiver is such that incident solar flux impinges on the underside of the evaporator dome. Because the internal surface of the dome is wicked it serves as the heat pipe evaporator during the sun portion of the orbital cycle. Also, because of the internal wicking the solar flux is evenly distributed throughout the dome thus the occurrence of hot spots is greatly reduced.

The entire cavity is wicked and the heat pipe transport fluid is sodium. During the sun portion of the orbit the sodium is evaporated off of the dome and condenses on the outside surface of the thermal energy storage (TES) canisters (thus melting the TES material "LiF-CaF₂" and storing energy to be used during the shade portion of the orbit), and the Stirling engine heater head tubes.

The TES material LiF-CaF₂ has a heat of fusion of 735 kJ/kg and its melting point is 1039 K. During the shade portion of the orbital cycle, heat is extracted from the TES material, now making the containment canisters the heat pipe evaporator and providing uninterrupted heat input to the engine for the entire orbit.

This conceptual heat receiver design is currently in the critical technology evaluation phase. The critical technology issues identified for the receiver are:

- thermal ratcheting
- evaporator dome fabrication
- identification of a wick system
- heat pipe operation

Brayton Cavity Heat Receiver  
Sundstrand Corp.

With the cavity heat pipe heat receiver all of the solar energy from the concentrator falls on a cylinder that forms the inner liner of the cavity and acts as a heat pipe evaporator during the sun portion of the orbital cycle. The energy is transferred to the sodium heat pipe working fluid by evaporating the sodium. The energy is then given up as the sodium vapor condenses on the Brayton engine working gas tubes. Condensation also occurs on the thermal energy storage (TES) canisters, storing energy in the TES material for operation during the shade portion of the cycle.

During the shade portion of the orbital cycle, the TES canisters act as the heat pipe evaporator, transferring energy to the Brayton engine working gas tubes thus, providing uninterrupted power during the shade portion of the cycle. These processes take place at very nearly isothermal conditions.

The TES material is lithium fluoride (LiF) which was chosen because it has a melting point at which the Brayton cycle has high efficiency, 1122 K and it has a high heat of fusion, 1087 kJ/kg. However, the fluoride salts, such as LiF, have very low thermal conductivities, resulting in poor heat transfer through the TES, which in turn, results in high working gas temperature swings as the system goes from sun to shade and back to sun. Also, they expand when melting which must be addressed in the receiver design to prevent canister failure.

Critical technology experiments are underway to determine designs that minimize the thermal conductivity effects and that will accommodate the void formed by the decrease in TES material volume when freezing.

SODIUM “HEAT PIPE” CAVITY
OBJECTIVES

The two objectives of this project are to fill a need that has, to date, been lacking in understanding the effects of melting and freezing of TES materials under microgravity.

- Analyses prior to this present effort have been based on simplified, 2-dimensional work. NASA-Lewis contracted with ORNL to develop a code based on what was regarded as an essential element in receiver applications -- 3 dimensions, and which would integrate all of the different thermo-physical aspects involved with melting and freezing. The code development is to include the condition of microgravity.

- The flight program is intended to supply the first experimental data of TES operation under microgravity. No such information exists. The data then becomes the reference against which the NORVEX code is compared. Retrieval of the experiment after flight will provide visual information as well as thermal data.

ORNL has completed their first effort for both 1-g and microgravity and is in the process of validating the program (checks for internal consistency and for agreement with known results).
THERMAL ENERGY STORAGE TECHNOLOGY (TEST) PROJECT

OBJECTIVES

• ANALYSIS OF TES MATERIALS BEHAVIOR - NASA/OAK RIDGE VOID EXPERIMENT, NORVEX (FUNDED BY CODE RP):
  
  - DEVELOP A COMPUTER PROGRAM TO PREDICT TRANSIENT BEHAVIOR (CONTINUOUS AND REPETITIVE SOLIDIFICATION/LIQUIFICATION) OF TES MATERIALS, PARTICULARLY VOID SHAPE AND LOCATION, UNDER MICROGRAVITY.

• MICROGRAVITY EXPERIMENTS (FUNDED BY CODE RX):
  
  - VERIFY CAPABILITY OF DEVELOPED COMPUTER CODE TO PREDICT VOID LOCATION AND THERMAL HISTORY OF TES UNDERGOING PHASE CHANGE IN MICROGRAVITY.
IN-REACH THERMAL ENERGY STORAGE TECHNOLOGY ("TEST")

Thermal energy storage is conventionally associated as being an integral part of the solar receiver, located in the focal region of the concentrator. TES serves to store heat during the sun period and transfer that heat to the working fluid during the shade period of an orbit. Better understanding of the operation of TES is required to meet the advanced solar receiver objectives of lower mass and longer life. A better understanding involves two thrusts -- analysis that describes all of the thermo-physical phenomena of TES undergoing phase change under microgravity, and a flight experiment to verify the analysis.

The schematic is configuration for experiment #1 in which a TES salt, LiF, is contained in an annular container.
IN-REACH THERMAL ENERGY STORAGE TECHNOLOGY ("TEST")

OBJECTIVES

- DEVELOPMENT OF COMPUTER PROGRAM TO PREDICT TRANSIENT BEHAVIOR OF TES MATERIALS

- VERIFY CAPABILITY OF COMPUTER CODE TO ANALYZE TES IN A MICROGRAVITY EXPERIMENT
THERMAL ENERGY STORAGE PROJECT

This chart shows the milestone schedule for the TES flight project. Four experiments are proposed with the first two paired for a single flight and the second two likewise.

The project is presently in the Engineering Development phase. Flight date for experiments 1&2 is March 1993 on the Hitchhiker M. Experiments 3&4 follow a year later. The phases in between are steps which address technical problems about the experiment itself, then to the flight structure, and finally launch. Safety is a concern throughout. Reviews are an important part of the process. The Flight Experiment Review takes place when the Engineering Development phase has been completed. All questions about the experiment -- justification, feasibility, instrumentation -- must be answered satisfactorily before the project can proceed to the Flight Development phase. Three reviews -- Preliminary Design Review, Critical Design Review, and the Flight Readiness Review -- ensure that the entire support structure and equipment is sound and ready for flight.

** TRW's data
AF MANTECH PROGRAM
HIGH EFFICIENCY, RUGGED GaAs/Ge CELLS

OBJECTIVES:
- Develop manufacturing technology for high efficiency (> 18% AMO) lightweight (<0.05 gm/cm²), large area (>4 x 4 cm²), space qualified GaAs/Ge cells.

ACCOMPLISHMENTS
- Demonstrated MOCVD growth, cell thinning and processing capable of meeting all goals above
- 4 cm x 4 cm cells, <4 mils thick exceeded 19% and 6 cm x 6 cm exceeded 17%
- Major space qualification tests completed
- Demonstrating and testing welded or soldered panel technology on lightweight substrates
- Developing high temperature contact system
SOLAR CELL TECHNOLOGY TRENDS

- Development of large scale, reliable MOCVD reactors for growth of thin films
- Thin, rugged GaAs/Ge replaced GaAs/GaAs cells
- High efficiency ($\eta > 18\%$), thin GaAs/Ge cell will provide much improved specific power performance
- Manufacturing cost of GaAs/Ge cell will be further reduced as demand increases
- Tight process control, quality management and automation are needed for advanced production cells
- Solar cells will continue to be "tailor-made" to meet various environment and mission requirements
- BOL, 1 sun AM0, $28^\circ C$ efficiency in early 1990's
  - Silicon $\eta > 17\%$
  - Single junction GaAs $\eta > 20\%$
  - Two junction cascade $\eta > 24\%$
- For significantly improved manufacturing technology, must have sustained demand. For few large production runs, return on investment not assured

GROWING THE SPACE STATION'S ELECTRICAL POWER PLANT

GALE R. SUNDBERG
NASA LEWIS RESEARCH CENTER
CLEVELAND, OHIO 44135

SUMMARY

For over a decade NASA LeRC has been defining, demonstrating and evaluating power electronic components and multi-kilowatt, multiply redundant, electrical power systems as part of our OAST charter. Whether we consider aircraft (commercial transport/military), Space Station Freedom, Growth Station, launch vehicles, or the new Human Exploration Initiative our conclusions remain the same: high frequency AC power distribution and control is superior to all other approaches for achieving a FAST, SMART, SAFE, VERSATILE, and GROWABLE electrical power system that will meet a wide range of mission options.

To meet the cost and operability goals of future aerospace missions that require significantly higher electrical power and longer durations, we must learn to integrate multiple technologies in ways that enhance overall system synergisms. This paper will challenge the way NASA is doing business in space electric power and propose some approaches for evolving large space vehicles and platforms in well constructed steps to provide safe, ground testable, growable, smart systems that provide simple, replicative logic structures, which enable hardware and software verification, validation and implementation.

AUTONOMOUS POWER EXPERT (APEX) FOR SPACE STATION FREEDOM ELECTRICAL POWER SYSTEM TESTBED APPLICATION

GOAL:
DEVELOP REAL-TIME AI SOFTWARE FOR PMAD OPERATIONS & CONTROL

APPROACH:
* COOPERATIVE (OAST/OSS) PROGRAM
* INCREASINGLY SOPHISTICATED KNOWLEDGE-BASED DESIGNS
* PROOF-OF-CONCEPT ON EPS TESTBEDS

SIGNIFICANCE:
* ENHANCED CREW EFFICIENCY THROUGH FASTER POWER OPERATIONS DECISIONS
* IMPROVED ELECTRICAL ENERGY UTILIZATION WITH OPTIMIZED LOAD POWER SCHEDULING
* INCREASED SAFETY PROVIDED BY RAPID ELECTRICAL FAULT DIAGNOSIS/RECOVERY
FUNDAMENTAL SYSTEM REQUIREMENTS

• MUST MEET MISSION REQUIREMENTS
  - RATED POWER, GOOD AVAILABILITY
  - ACCOMMODATE VARYING LOAD PROFILES
  - USER FRIENDLY LOADS
  - CAPABLE OF GROWTH

• MUST BE SAFE
  - PROTECT WIRES AND EQUIPMENT
  - ELIMINATE FIRE HAZARD
  - CREW
  - SYSTEM STABILITY - STEADY STATE AND TRANSIENT
  - REDUNDANCY FOR LIFE CRITICAL LOADS

• ACCURATE REAL TIME STATUS
  - LOAD MANAGEMENT
  - DIAGNOSTIC AND CONTROL

• DESIGN QUALIFIED ON GROUND, ASSEMBLED IN SPACE
LARGE SPACE POWER PLANTS MUST BE

WHY MODULARITY

• VHSIC, Advanced VLSI chips driving the power supply function to become highly distributed

• Power cabling within the racks less complex and lower in mass

• Less mass and loss especially for 5V distribution for electronic components

• Modules can be designed using high internal switching frequencies; the result is lower mass and volume and higher reliability

• Modular design provides efficiency advantages at partial loads

• Modularity allows graceful degradation

• Extra redundancy can be added with small increase in mass

• Modularity will permit standardization and commonality; diversified power supply efforts would be too costly
OVERVIEW

• MODULARITY OPENS THE DOOR TO STANDARDIZATION OF POWER SUPPLIES, COMMONALITY, AND SUBSTANTIAL COST SAVINGS

• THE DEVELOPMENT OF STANDARDIZED SPACE QUALIFIED POWER SUPPLY BUILDING BLOCK MODULES CAN BENEFIT THE SPACE STATION PROGRAM, FUTURE SPACECRAFT, AND THE NEW MOON AND MARS INITIATIVES

• HYBRIDIZED, HIGH SWITCHING FREQUENCY MODULES CAN IMPROVE EFFICIENCY, SAVE MASS, INCREASE RELIABILITY AND REDUCE POWER SUPPLY COSTS SIGNIFICANTLY

• TWO SPECIFIC APPLICATIONS ARE DISCUSSED:
  A) USER END DC/DC POWER SUPPLIES
  B) BULK CONVERTERS
INTRODUCTION
TARGET APPLICATIONS
(DISCUSSION OF VIEWGRAPH 6)

Space Station Freedom cost models show that the life cycle cost of a kilowatt of power installed is on the order of twenty million dollars. At mature operations, the station will use hundreds of power supplies to feed house keeping and user loads. Proposed standard modular dc power supplies can provide significant cost, mass, and efficiency savings for the program.

The development of a small number of standard space qualified power supplies with the Space Station as an initial consumer may have a significant benefit to future spacecraft and the new Moon and Mars initiatives.

To the users of the Station, the new approach will permit the use of "distributed" power supply design with the user able to specify just what is needed and use it only where needed. The cost of user power supplies may be $70 to $80 million; R&D to reduce it may be worthwhile.

The modular design approach can also provide benefits to the bulk conversion application. The proposed design incorporates multiple modular converters in the primary/secondary bus interface that can provide significant cost, mass, efficiency, and reliability improvements for the program while meeting the design requirements.
POWER SUPPLIES FOR FREEDOM

- USER-END POWER SUPPLIES ON FREEDOM FOR HOUSEKEEPING AND PAYLOADS
  - APPROX. 2000 POWER SUPPLIES OF FLIGHT HARDWARE
  - ESTIMATE MORE THAN 5000 UNITS OF NON-FLIGHT HARDWARE FOR DEVELOPMENT WORK
  - ESTIMATED COST IN EXCESS $80 MILLION FOR FLIGHT AND DEVELOPMENT HARDWARE

FOCUS ON DC POWER SUPPLIES
- HALF OF ALL POWER SUPPLIES (APPROX. 1000) FEED DC LOADS
- 5, ±15, 28 VOLTS ARE TYPICAL OUTPUT VOLTAGES

- BULK CONVERTER UNITS (DC TO DC CONVERTER UNIT, DDCU)
  - 12.5 kW UNITS INTERFACE 160V POWER SUPPLY BUSES TO 120V DISTRIBUTION BUSES
  - 28 UNITS, 350 kW ONLINE CAPACITY AT ASSEMBLY COMPLETE
THE CONCEPT
AND CHARACTERISTICS
MODULARITY CONCEPT
(DISCUSSION OF VIEWGRAPHS 7, 8, AND 9)

Manufacturers of power supplies for space applications have used modular designs before to minimize the development costs of units of different size. Loral, for example, has built half, one, and two kilowatt units using 250 W modules. The European and Japanese partners of Space Station Freedom have been considering the use of two to four kW dc/dc converter modules to build larger converters interfacing the station power distribution. These units are based upon discrete electrical components.

Recently, developments in hybridized power supplies using high switching frequencies in the 100 kHz to 10 MHz range provide the basis for pushing this modular design approach much further with significant advantages.

Several 20 to 250 W dc/dc converters designs have been developed at MIT, CALTECH, VPI, AT&T and other places and some are now available via their industrial partners. These designs are very compact and have been hybridized. None are space qualified yet. If used as building blocks, they offer many advantages not feasible in the discrete component designs cited above.

None of these units have been space qualified; the proposed development effort, therefore, is necessary:
MODULARITY CONCEPT

• CONCEPT: BUILD DC POWER SUPPLIES USING SMALL, HIGH-SWITCHING-FREQUENCY HYBRIDIZED MODULES.

• TECHNICAL AND ECONOMIC FACTORS
  • EFFICIENCY
  • RELIABILITY
  • EMI
  • FLEXIBILITY
  • CONTROL

PROPOSED 100 W STATE-OF-THE-ART MODULE

JPL-NSCAT INSTRUMENT (1989)
120 W POWER SUPPLY DISCRETE COMPONENT
EFFICIENCY

(DISCUSSION OF VIEWGRAPHS 10, 11, AND 12)

Efficiency is perhaps the most important consideration. One kW of installed capacity of the Space Station amounts to approximately twenty million dollars of Life Cycle Costs (LCC). Thus, a one percent increase in the efficiency of the proposed 100 Watt converter costing about $10,000 may save twice that in LCC. In design, every effort should be made to increase the efficiency of the module as well as the whole converter.

Because the final rectification stage of a module results in a voltage drop, the efficiency of the module is a sensitive function of its output voltage. Viewgraph 11 shows the efficiency of state of the art modules as a function of the output voltage. The same viewgraph shows that if techniques such as synchronous rectification and design optimization are applied, higher efficiencies in the shaded band can be achieved. It is sufficient to see in this overview that a 2% to 4% improvement in efficiency may be feasible, assuming that about 37.5 kW of the station power goes to dc loads. This improvement in the efficiency is equivalent to 0.75 to 1.5 kW power savings or a life cycle cost benefit of 15 to 30 million dollars.

Another aspect of modular design is the improvement in the efficiency at partial loads. A typical efficiency curve for a power converter is shown in Viewgraph 12; the efficiencies at partial and "keep alive" levels of operation are quite low due to high parasitic light load losses. If a modular design is used in which a provision is made to turn off the unloaded modules, the synthesized efficiency-load characteristics would look like that shown in Viewgraph 12. Operation at partial load and at "keep warm" levels are quite common. Measureable savings can be made in the parasitic losses at lightly loaded conditions.
EFFICIENCY

- Increases in efficiency occur at two levels:
  - At the module level, 2% - 4% increase over current practice
  - At the bulk conversion level, 2% - 4% system efficiency increase due to improved efficiency at partial loads by switching off unloaded modules
Module Efficiency

State-of-the-art feasible range

Current practice

2%-4% increase in efficiency translates to 0.75 to 1.5 kW increase in power delivered.
EFFICIENCY: MODULAR vs. NONMODULAR UNITS

- Modular Power Supply with 10 Modules
- Nonmodular Power Supply
The reliability of a power conversion subsystem is dependent on the following elements of design:
1) Thermal stress; 2) Electrical stress; 3) Parts count and complexity; 4) Selection of parts (class of part).

Improved reliability is dependent on thermal stress. Operating temperature of a power conversion device is dependent on heat dissipation, mass radiating area, and cooling methods. Inherently, the smaller size of hybrids gives the designer the flexibility to optimize the size for cooling effectiveness. Hybridized power converter modules have a low profile making it easier to remove heat; cooler junction temperatures add significantly to the life of the circuit.

We have seen earlier that as the switching frequency increases, the sizes of the inductors and capacitors decreases. One benefit of smaller size is that it permits use of highly reliable ceramic capacitors instead of tantalum capacitors.

Although it remains to be shown, the improvements may be so substantial (up to 250,000 hrs MTBF) that from a reliability point of view, the hybrid circuit may be treated as a single part. If this is demonstrated, the reliability of the whole power distribution system can be improved significantly.

Larger power converters built by paralleling smaller modules have inherent fault tolerance capability. The failure of a module need not cause the failure of the whole unit. In space applications requiring redundancy, the modular approach provides some elegant low mass, high efficiency design options.
RELIABILITY

- CERAMIC FILTER CAPACITORS FOR HIGH FREQUENCY CONVERTERS ARE MORE RELIABLE THAN TYPICALLY USED TANTALUM CAPACITORS

- HYBRID CONSTRUCTION HIGHLY RELIABLE

- HIGHER EFFICIENCY AND LOW PROFILE CAN IMPROVE THERMAL CONTROL

- MODULARITY PROVIDES GRACEFUL DEGRADATION

- BUILT-IN SPARES CAN PROVIDE ADDITIONAL REDUNDANCY
The EMI standard (MIL-STD-461B) places absolute limits on powerline currents as a function of frequency irrespective of the power rating or voltage of the power converter. The permissible conducted current decreases by 30 dBs/decade to 2 MHz and then remains constant.

It is easier to design a low power module to meet the EMI specifications than a high power unit because of the lower bus current and resulting lower conducted EMI current. When multiple modules are placed in parallel, care must be taken to ensure that the currents do not exceed the EMI limits. Synchronizing the modules helps reduce the generated EMI currents. If all modules used in a large system like the Space Station are designed to use the same switching frequency, say, 100 kHz, or multiples thereof, synchronization can be easily implemented.

Numerous commercial hybrid power supply module vendors indicate compliance with various EMI specifications including MIL-STD-461B. Due to high switching frequencies, small EMI filters are required.
EMI CONTROL

- Prototype modules have already shown compliance with MIL-STD-461B

- Modules can be synchronized to enhance EMI control

- Small external filters can provide further improvements
MASS AND VOLUME REDUCTION
(DISCUSSION OF VIEWGRAPH 15)

Dr. Cúk of Cal Tech points out that a rough figure of merit for current switching rate capability of semiconductors is the product of power and switching frequency. For a given power level, progressively higher frequencies lead to smaller magnetics and overall mass. Although precise comparisons based upon the figure of merit cannot be made from available product data, because a modular design would not necessarily use individual casings for each module, and because frequency of operation would be higher, the mass of the modular design is expected to be less compared to a single unit design.

A higher figure of merit tends to represent a lower mass. Although the improvements do not continue with ever increasing frequency, the present state-of-the-art permits the use of frequencies up to 2 MHz, although some designs as high as 10 MHz have been prototyped.

Mass and volume improvements are possible because high switching frequencies require physically smaller filters.

Some of the mass reduction provided by the modular design approach can be used to further improve the efficiency. This can be accomplished by slightly larger magnetics which may reduce hysteresis losses, or by increasing redundancy by using an increased number of units in parallel. Also some mass and volume savings can be traded to get better heat removal and to add redundant units to increase reliability and fault tolerance.
MASS AND VOLUME

• HIGHER SWITCHING FREQUENCIES LEAD TO LOWER POWER SUPPLY MASS

• HIGHER SWITCHING FREQUENCY AND HYBRIDIZATION LEADS TO COMPACT SIZE

• ESTIMATES OF MASS SAVINGS WILL BE DISCUSSED FOR EACH APPLICATION
USER END POWER SUPPLIES
Advanced high density components (e.g., VHSIC) and interconnection technologies force the power conditioning function to become highly distributed throughout the entire electronics system.

Future systems will contain increased numbers of power conditioning modules, each of which processes smaller amounts of power and is located closer to the electronic load circuits that it powers. The Module output power will be as required.

The advantages of distributed power include: a) Reduction in the complexity of system wiring and associated shielded cables; b) Elimination of voltage drop associated with distribution from a central power converter, especially at lower input voltages; c) Improved reliability, reduced common mode noise; d) Elimination of resonances in cables and; e) Improved transient response due to high frequency converter switching.

A number of control and safety features can be easily built-in into the modules. This further enhances the usefulness of the power supplies to the end users.
The usage of 120 Vdc distribution inside the racks would result in a smaller cable mass. When parallel power supply modules are used, only the number of units required by the load will be turned on. This will result in higher efficiency and lower parasitic losses.

These modules can be controlled via an IEEE-1553B bus interface. They can operate over the broad input voltage range specified and provide the necessary isolation to the load. They can provide current limiting, soft start, and short circuit protection. These power supply modules can be used as a single power unit and in addition multiple units can be utilized for bulk converters interfacing primary and secondary distribution.
APPLICATION CHARACTERISTICS

- TAILOR POWER SYSTEM USING COMMON POWER SUPPLY COMPONENTS WHERE THEY ARE NEEDED

- DISTRIBUTED POWER SUPPLIES
  - BOARD LEVEL POWER SUPPLIES OPTIMIZE POWER DISTRIBUTION
  - LOWER MASS AND WIRING COMPLEXITY DUE TO 120V DISTRIBUTION IN THE RACKS
  - USE ONLY WHAT IS NEEDED

- SPECIAL FEATURES: MODULES CAN PROVIDE
  - IMPROVED PROTECTION CHARACTERISTICS
    - CURRENT LIMITING CAPABILITY
    - IMPROVED SHORT CIRCUIT PROTECTION
    - IMPROVED TRANSIENT RESPONSE

- SAFETY CHARACTERISTICS
  - ELECTRICAL ISOLATION
  - ABILITY TO HANDLE INPUT VOLTAGE VARIATION

- CONTROLLABILITY
  - DIGITAL CONTROL AND IEEE-1553 BUS INTERFACE

BULK CONVERTER APPLICATION
BULK CONVERTER APPLICATION

- MODULAR DESIGN

- ONE FOR ONE REPLACEMENT OF BULK CONVERTERS (DDCUs)

- A SWITCHING MATRIX IS USED WITH MODULAR CONVERTERS TO REDUCE BOX COUNT
PRESENT ARCHITECTURE [SPACE STATION FREEDOM (SSF) ELECTRICAL POWER SYSTEM (EPS)]  
(DISCUSSION OF VIEWGRAPH 19)

VG-19 shows the present concept of the SSF EPS architecture in-board of the alpha gimbal. The power rating of SSF is 37.5 kW generated by photovoltaic panels. The spacecraft is divided into two separate 18.75-kW distribution systems. Primary power is generated at 160 Vdc. In the present baseline, four main bus switching units (MBSUs), one in each quadrant of the EPS network, control the distribution of power to the elements of Space Station Freedom. The four MBSUs supply 160-Vdc power to 28 dc-to-dc Converter Units (DDCUs) that interface with the loads via dc Power Distribution Control Units and with other devices.

Twenty eight buses in the space station's utility tray provide the interface between the four MBSUs and the 28 DDCUs. The DDCUs are associated with the loads and mounted on or near them. A single dedicated dc bus feeds each DDCU.

The DDCUs convert 160-Vdc power to regulated 120 Vdc. Each is rated at 12.5 kW, and provides electrical isolation between the 160-Vdc bus and the 120-Vdc bus.
The proposed architecture is similar to the present one, except for the location and design approach to the utilization of the DDCUs.

VG-20 depicts the proposed EPS architecture. The DDCUs are shown adjacent to the MBSUs. This is a significant change, reflecting their proposed relocation on the central EPS PMAD pallet instead of on the surface of modules and nodes. By locating the DDCUs in a single envelope, see VG-21, flexibility is gained in sizing the units. Instead of each DDCU being dedicated to a single fixed module, node, or pallet, the DDCUs are available to be switched selectively to any combination of buses, as the need arises. The details of this design are provided below.

As in the present architecture, the proposed centralized DDCUs are internally modularized. Of these, approximately one-half are active at any given time; the others are "connected" spares (usually turned off).

Individual modules within the DDCU (DDC module) may be sized in the range of 250 W to 5 kW.
The approach, see VG-21, is to use multiple DC/DC converter modules instead of a single 12.5-kW interface DC/DC converter. By using switches, these modules can be switched to a desired secondary bus and provide the desired power requirements to a particular load. A failure of a single module does not impair power rating, as a replacement redundant module is switched into service. The result of this technique is to provide high levels of reliability without requiring the required installed kilowatt capacity of a single large interface DDCU. The reduction in installed DDCU capacity will result in a relatively proportional mass reduction. In line with the reduction in active DDCU capacity, the part load losses are expected to be proportionally reduced, resulting in improved EPS efficiency and reduced cost.

• OPTIMIZED, STANDARDIZED, AND SPACE QUALIFIED MODULES REDUCE DEVELOPMENT COSTS COMPARED TO NONSTANDARDIZED DESIGNS

• RELIABILITY INCREASES REQUIRE LESS LOGISTICS, ON-ORBIT STORAGE, AND MAINTENANCE COSTS
RECOMMENDATIONS
RECOMMENDATION TO OAST

- Fund joint development effort LeRC-JPL
  - JPL module development
  - LeRC: packaging development

- Develop space qualified 10W through 250W modules
  - 2 to 4% higher efficiency than existing units
  - State-of-the-art switching frequency
  - Compliant with requirements of space station

- Demonstrate parallel operation
  - Develop control logic
  - Develop breadboards and demonstrate parallel operation
  - Demonstrate performance over the full range of design loads

- Demonstrate bulk converter arrangement
  - Multiple-module, multi bus configuration
  - Electrical isolation
  - Fault tolerance
RECOMMENDATIONS TO THIS WORKSHOP

- PLACE HIGH PRIORITY ON THE PROPOSED MODULAR POWER SUPPLY DEVELOPMENT EFFORT

- EMPHASIZE BOTH END-APPLICATIONS

Power Beaming Options for the Space Station

Presented by
Dr. Peter E. Glaser
Vice President
Arthur D. Little, Inc.
Cambridge, MA

Presented to
NASA, OAST Workshop
January 16-19, 1990
Dallas, TX
Power plant locations need to be assessed

- Integrated with Space Station
- Tethered
- Free-flying (beamed power)
- Earth-based (beamed power)
Power is prerequisite for Space Station evolution

- Near-term: 25 kW (supplemental power)
- Mid-term: 100-500 kW (mission support)
- Long-term: > 500 kW (infrastructure element)
Beamed power has potential benefits

• Flexibility of power plant location
• Reduced drag on Space Station
• Orbital altitude optimized for space shuttle
• Growth path to power supply for exploration missions
There are two major beamed power options

- Lasers
  - Generation (demonstrated)
  - Transmission (demonstrated)
  - Reception (to be developed)

- Microwaves
  - 2.45 GHz (end-to-end system demonstrated)
  - 35 GHz (demonstrated in laboratory)
Power beaming requires in-space demonstration

- Recommended at planning conference for ISY
- Proposed by Center for Space Power (Texas A&M)
- Investigated by Institute of Space and Astronautical Science (Japan)
Space Power System Technology (ISAS)

Working groups

- System technology
  - Microwave power reception

  - Spacecraft environment
  - Interaction with space plasma
  - Communication system
  - Biological effect
Planned TSS experiment (enabling)

Deployed satellite

Satellite ready for deployment

Diagnostics of plasma environment with tether attached to 12 meter expandable boom
Microwave transmission experiment considered for space shuttle cargo bay
Possible power transmission configuration from space shuttle to free-flying platform
Power beaming is the enabler for future missions

- **Generic technology development**
- **Leo/Heo**
  - Supplemental power to Space Station and co-orbiting platforms
- **Moon & Cislunar Space**
  - Power to transportation systems and lunar bases
- **Planets**
  - Power for use on Earth
  - Power for use on Earth
- **Solar System**
  - Extraterrestrial energy and materials resources to benefit humanity

Timeframe:
- 1995
- 2000
- 2005
- 2010
- 2015
- 2020
Beamed power can be developed to support Space Station when:

• Experiments are undertaken in the near-term
• Environmental and societal factors are considered
• Cooperative programs with industry are developed
• Beamed power technologies support multiple space power system applications

SUMMARY

• In the shorter term the dedicated SPE Fuel Cell and SPE Elecrolysis approach meets many of NASA energy requirements including:
  - Low system mass
  - Long lifetimes
  - Stable voltage
  - Passive phase management

• In the longer term the unitized regenerative SPE Fuel Cell offers additional advantages:
  - Lower complexity
  - Higher reliability (lower number of parts/passive fluid and thermal management)
  - Lower mass
INTEGRATED POWER AND ATTITUDE CONTROL SYSTEM (IPACS) TECHNOLOGY DEVELOPMENTS

PRESENTED TO:
TECHNOLOGY FOR SPACE STATION EVOLUTION WORKSHOP

16-19 JANUARY 1990

CO-AUTHORS:
DAVID B. EISENHAURE, SATCON TECHNOLOGY CORPORATION
BOB BECHTEL, NASA MARSHALL SPACE FLIGHT CENTER
RICHARD HOCKNEY, SATCON TECHNOLOGY CORPORATION
RON OGLEVIE, CONSULTANT
MITCH OLSZEWSKI, OAK RIDGE NATIONAL LABORATORY
Integrated Power and Attitude Control System (IPACS) studies performed over a decade ago established the feasibility of storing electrical energy in flywheels and utilizing the resulting angular momentum for spacecraft attitude control. Such a system has been shown to have numerous attractive features relative to more contemporary technology, and is appropriate to many applications (including high-performance slewing actuators). Technology advances over the last two decades in composite rotors, motor/generator/electronics, and magnetic bearings are found to support the use of IPACS for increasingly sophisticated applications. It is concluded that the concept offers potential performance advantages as well as savings in mass and life-cycle cost.
OVERVIEW

- FEATURES & MISSION APPLICABILITY
- TECHNOLOGY ADVANCEMENTS SUPPORTING IPACS
  - ROTORS--MATERIALS & SHAPE
  - MOTORS/GENERATORS
  - BEARINGS
- SYSTEM-LEVEL TRADE COMPARISONS
- CONCLUSIONS & RECOMMENDATIONS
DISCUSSION VIEWGRAPH #2

The IPACS concept provides for the storage of electrical energy as kinetic energy in mechanical rotors. Energy storage wheels can generally be made to provide higher energy densities than most other long-life energy storage devices. When significant amounts of energy are stored in this fashion, appreciable amounts of angular momentum are produced. This angular momentum may be utilized for attitude control of the spacecraft.

To accomplish the dual function of energy storage and attitude control, the IPACS wheels are configured in such a way that they will satisfy simultaneous energy (power) and momentum (control Torque) demands, and to do so with negligible interaction between the two functions. Although this may seem to be an imposing requirement, it is easily accomplished with wheel configurations that are similar to the momentum wheel (MW) and control moment gyro (CMG) configurations appropriate to many applications. In most spacecraft applications the IPACS units replace the functions performed by batteries and momentum storage/transfer equipment. The obvious merits of IPACS are its potential for satisfying two functions with common hardware and long life. Similar components have demonstrated very long life in space missions.
INTEGRATED POWER AND ATTITUDE CONTROL SYSTEM (IPACS) CONCEPT
The energy storage wheel historical legacy is rich with focused and supporting technology developments that are applicable to the development of an advanced IPACS. This is particularly true for the advances in composite rotors, magnetic bearings, and motor/generator/circuitry technology that have occurred during the last 12 years. The three basic technology areas that are the fundamental components of an advances IPACS are listed on the left side of the viewgraph. Improvements in power processing circuitry, magnetic materials, and magnetic system design have increased the energy recovery efficiency (round-trip charge/discharge cycle efficiency) from approximately 60% to over 85%. In a spacecraft photovoltaic power system, this efficiency has a strong effect on the overall system sizing (including the solar array).

During the last decade, magnetic bearing technology has gone from an interesting laboratory curiosity to a proven technology with several flight applications having operated successfully in orbit, and many more applications proven in the laboratory. Notable among these are a Soviet flight experiment of a magnetically suspended reaction sphere, the flight of a rotating scanner with magnetic bearings by the Sperry Flight Systems Division, and the operational flight of European reaction wheels with magnetic bearings. Also, the use of magnetic suspension for vibration isolation and high-accuracy pointing have been thoroughly studied and proven in the laboratory. The merits of very low friction losses, maintenance-free long life, and freedom from vibration disturbances, for example, are very attractive. These suggest "leap-frogging" past the use of ball bearings with the attendant problems of lifetime, vibration, maintenance, and the long-duration testing needed to validate bearing design.

The composite rotor technology is the key to achieving higher energy densities. The recent Department of Energy composite energy storage wheel development and testing programs have provided a valuable legacy that was not available a decade ago. Considerable data have been provided on various materials, rotor shapes, composite rotor fabrication, and testing techniques. In addition, advantages in basic composite materials technology are continuing to be made at a high rate.

The advances in the three technology areas described above suggest that an advanced IPACS employing a composite structure rotor, magnetic bearings, and advanced motor/generator/electronics is a feasible and cost-effective replacement for the systems used in the contemporary spacecraft of today.
CONCLUSIONS: • CHARGE/DISCHARGE EFFICIENCY MUCH IMPROVED — FROM 60% TO 85%
• LAB VERIFICATION ACCOMPLISHED IN THREE BASIC TECHNOLOGY AREAS
DISCUSSION VIEWGRAPH #4

The historical development of the three key technology areas is shown in the viewgraph.

ENERGY CONVERSION - The advent of the samarium cobalt magnets permitted IPACS energy conversion efficiencies to first become competitive with batteries. Significant improvements in magnetic materials have been made subsequently. The advent of improved circuitry, such as metal oxide field effect transistors (MOSFETS) has greatly reduced the switching and conduction losses. The combined result is an improvement in roundtrip conversion efficiencies from approximately 60% in the early 1970's to an estimated 85% today. Further improvements in circuitry are projected to push the efficiency into the 90% range by the early 1990's.

ROTOR DESIGN - Early IPACS's employing non-isotropic rotor materials (such as steel or titanium) achieved a deliverable system energy density of approximately 11 WH/KG (including the mass of the rotor, energy conversion, bearings, gimbals, and vacuum housing equipment). The most efficient rotor shape appeared to be the constant stress (or exponential) shape. Subsequent development of the non-isotropic (composite) materials and the composite rotor design studies sponsored by the U.S. Department of Energy (DOE) in the late 1970's and early 1980's produced a legacy of valuable design data. Annular (or hoop) type rotor shapes were found to utilize the non-isotropic properties of composites most advantageously and produce the highest energy densities. An advanced IPACS concept designed in 1984 had an expected deliverable system energy density of 22 WH/KG. This included all mass items chargeable to energy storage and attitude control actuators, and had very conservative derating factors included for a 20 year fatigue life and structural factors for safety. Newer composite materials and less conservative safety factors will now permit the achievement of about 60 WH/KG. It is safe to project that system energy densities of 100 WH/KG will be achievable by the early 1990's.

BEARING/SUSPENSION - Ball bearing systems employing thin-film lubrication have proven to be highly reliable and have modest friction losses. Magnetic suspensions offer the advantages of lower losses, very long life, and improved freedom from vibration disturbances. Laboratory testing of the NASA/LaRC Annular momentum control device (AMCD), and the U. S. Air Force Materials Laboratory (AFML) magnetically suspended reaction wheel have established their feasibility. Subsequent flights of a magnetically suspended scanner, reaction wheels with magnetic bearing on the European Spot spacecraft, and a Russian reaction sphere experiment have demonstrated operational feasibility. Large angle magnetic suspensions have been developed which combine the dual functions of a magnetic spin bearing and a rotor gimbal system.
Technology advances support IPACS
DISCUSSION VIEWGRAPH #5

The viewgraph shows an early IPACS design this concept was developed by Rockwell International under contact to NASA. This concept utilized a titanium constant stress rotor, ball bearings, and a permanent magnet motor. This system demonstrated a deliverable system energy density of approximately 11 WH/KG (including the mass of the rotor, energy conversion, bearings, gimbals, and vacuum housing equipment).
INTEGRATED POWER AND ATTITUDE CONTROL SYSTEM (IPACS) DESIGN CONCEPT
EXISTING TECHNOLOGY (1970)
A novel advanced IPACS system employing a large angle gimbaling magnetic bearing is shown in the viewgraph. This system provides a suspension which serves the dual functions of a magnetic spin bearing and a rotor gimbal system. The concept includes spherically shaped armature and stator surfaces. It permits tilting the rotor through angles up to approximately 20 degrees with only a small penalty in bearing mass (approximately 3% of the rotating mass). This additional bearing mass to obtain the gimbaling function is quite small when compared to more conventional gimbal ring structures and six axis torquers which have masses approximately equal to the gimbaled mass. For space station type applications, IPACS rotors have an excess of angular momentum and can satisfy the attitude control requirements within this gimbal angle constraint.

DISCUSSION VIEWGRAPH #7

Viewgraph depicts an artist conception of the system described in the prior viewgraph.
DISCUSSION VIEWGRAPH #8

Some of the advantages of magnetic bearings for spinning rotor applications are summarized in the viewgraph. The suspension is actively controlled in three degrees of translational freedom and two of the rotational degrees of freedom. For this reason, the suspension can also be employed as both a translational and rotational structural vibration damping actuator. The actively controlled magnetic suspension can be used for the compensation of the rotor dynamic resonances. The control schemes provide for gain scheduling as a function of rotor speed so as to minimize rotor deflections and interaction with rotor dynamic resonances.
MAGNETIC BEARING ADVANTAGES

LOW LOSSES
- FRICTION/POWER LOSSES SMALL RELATIVE TO BALL BEARINGS

ROTOR VIBRATION SUPPRESSION
- LOW-BANDWIDTH SUSPENSION ISOLATES ROTOR VIBRATION SOURCES
  - ROTOR BALANCE REQUIREMENTS EASED
  - ACTIVE SUSPENSION FACILITATES ACTIVE CONTROL OF ROTOR DYNAMIC RESONANCES

DISCUSSION VIEWGRAPH #10

Over the last ten years, the government has funded the design and development of a large number of composite flywheel rotors. This research, which received early support from NSF-RAND, has recently been funded almost exclusively by DOE and its predecessor, ERDA. As indicated on the viewgraph, this program has resulted in the development and test of ten composite rotor systems.

In addition to the DOE-developed systems, a number of promising composite systems exist that DOE ruled out for consideration based on either high cost or unavailability. These systems include metal matrices, such as boron/aluminum or silicon carbide/aluminum, and more conventional composites, such as boron/epoxy. Usable energy densities of approximately 200 Wh/kg have been demonstrated with advanced graphite rotors.

DISCUSSION VIEWGRAPH #11

Recently significant new research was conducted at Oak Ridge National Laboratory (Martin Marietta). On October 17, 1985, an experimental energy storage demonstration was conducted in Oak Ridge. A small flywheel rim denoted as Demo 1A was constructed of carbon composites and dynamically tested in a spin test chamber at the Oak Ridge Gaseous Diffusion Plant. One low speed run was conducted to permit trim balancing, and then the unit was accelerated to a speed of 1055 m/s. The construction of this demonstration unit is similar to the planned construction for the outer portion for larger flywheel rims. The success of this early demonstration unit provides a confirmation of the ability to fabricate, assemble, and test thick-walled composite sections.

Both the specific energy (89 Wh/kg) and the total energy (7.687 MJ) of the flywheel (rim and hub) tested exceeds any reported performance of the DOE flywheel development program. Especially impressive is the fact that the rim specific energy of 500 wh/kg is an operational value not an ultimate (at failure) figure.

Since this early test, a number of additional rims have been fabricated and tested. As indicated by these results, failure of the rim occurred at a peripheral velocity of 1405 m/s. At this speed, the rim specific energy was 878 kJ/kg. Based on this failure point, it appears reasonable that an operating speed of 1220 m/s can be used with confidence. At this speed, the rim specific energy is 663 kJ/kg. The performance of these flywheels represents a significant advance over previous rotors.

For comparison nickel nitrogen batteries used in the Hubbel space telescope has a system energy density of less than 20 watt hours per kg at a 50% depth of discharge.
OAK RIDGE FLYWHEELS DEMONSTRATED IMPRESSIVE GAINS

SPECIFIC ENERGY (kJ/kg)

KINETIC ENERGY AT FAILURE (MJ)
DISCUSSION VIEWGRAPH #12

The viewgraph presents the system mass density of the various candidates, and illustrates the need for trading energy storage candidates on a system level basis. The advantage of IPACS is attributable primarily to its higher energy conversion efficiency and the elimination of the need for control moment gyros.
COMPARISON OF SYSTEM MASS (IOC)

LEGEND:
- THERMAL CONTROL
- CONTROL MOMENT GYROS
- ENERGY STORAGE
- POWER GENERATION, PROCESSING, AND CABLES
DISCUSSION VIEWGRAPH #13

Life-cycle cost data for the three system was also developed and is given in the viewgraph. The data is normalized to the IPACS cost at IOC and presumes that additional equipment is added to the system over the first five years to double its power capacity. The data also includes operational and servicing costs. It can be seen that the IPACS approach results in considerable cost savings, both for initial development and operations.

CUMULATIVE TOTAL COST (NORMALIZED TO IPACS AT IOC)

TIME FROM IOC (YEARS)

IOC GROWTH CONFIGURATION
DISCUSSION VIEWGRAPH #14

Key features of the approach are outlined in the viewgraph.
PRINCIPAL FEATURES OF IPACS

- PROVIDES ENERGY STORAGE & MOMENTUM TRANSFER (ATTITUDE CONTROL)

- VERY LONG LIFE (MANY CYCLES)

- SUPPORTS HIGH PEAK POWER

- PERFORMANCE
  - HIGH CHARGE/DISCHARGE CYCLE EFFICIENCY: > 85%
  - HIGH ENERGY DENSITY: > 22 Wh/kg (CONSERVATIVE)

- EASILY ADAPTED TO LARGE ATTITUDE MANEUVER REQUIREMENTS

- ADAPTABLE TO MANY MISSIONS AND APPLICATIONS--COST/WEIGHT ADVANTAGES FOR MOST OF THEM
Based on the key features of the IPACS design some general guidelines for the applicability of the concept to various space missions have been derived and are summarized in the viewgraph. Missions include a Space Station, various low earth orbital spacecraft, and a geosynchronous orbit spacecraft (Tracking and data relay satellite). The IPACS was found to be quite viable for all these applications.

More recently, greater emphasis has been placed on the rapid attitude slewing maneuvers required by some surveillance spacecraft and the Strategic Defense Initiative (SDI) applications. In some of these applications, not only is a great deal of transferable momentum needed, but the kinetic energy of the slewing body is also quite large. The energy transfer required is so large that it imposes very large peaking torquing power requirements (many horsepower). The IPACS capability to store and deliver high peak power, and regeneratively brake rapid slewing maneuvers, is ideally suited to these applications.
IPACS MISSION APPLICABILITY

MOST APPROPRIATE FOR MISSIONS/APPLICATIONS REQUIRING:

• BOTH ENERGY STORAGE & MOMENTUM TRANSFER ATTITUDE CONTROL

• MODERATE TO LARGE CONTROL REQUIREMENTS (SUCH AS RAPID SLEWING MANEUVERS, OR MOMENTUM STORAGE REQUIREMENTS)

• HIGH CHARGE/DISCHARGE CYCLE LIFE

OR

MISSIONS THAT MIGHT OTHERWISE EMPLOY PHOTOVOTAIC/BATTERY SYSTEMS & MOMENTUM TRANSFER EQUIPMENT
The IPACS concept is found to be attractive for many space missions and offers savings in performance, system mass, and cost. In addition to the more traditional applications, it is emerging as a high-performance slewing actuator candidate for surveillance and SDI missions, which require large peak slewing power transfer as well as momentum transfer.

The fundamental IPACS technologies in the three basic areas of rotor design, energy conversion, and magnetic bearings are now mature and will support the development of advanced IPACS applications. It remains to integrate these three fundamental technologies into flight type units and validate their performance in the laboratory. It is recommended that such a technology program be implemented to support future applications.
CONCLUSIONS AND RECOMMENDATIONS

- IPACS CONCEPT FEATURES ATTRACTIVE FOR MANY SPACE MISSIONS/APPROACHES

- TECHNOLOGY ADVANCES IN 3 BASIC AREAS NOW MATURE
  - COMPOSITE ROTORS
  - MAGNETIC BEARINGS
  - MOTOR/GENERATORS

- WILL SUPPORT ADVANCED IPACS DEVELOPMENT

- OFFERS PERFORMANCE ADVANTAGES, AND SAVINGS IN COST AND MASS

- RECOMMEND IPACS TECHNOLOGY DEVELOPMENT

Automation of Space Station Module Power Management and Distribution System

Prepared by
Robert Bechtel, Dave Weeks
and Bryan Walls
for the
Technology for Space
Station Evolution Workshop
This vugraph describes the primary reasons for needing automation of the electrical power system within the habitation and laboratory modules of Space Station Freedom. As the systems become more complex and are required to distribute power to a larger number of loads, these factors will become increasingly more important. Future needs in the automation area will necessitate the development of advanced techniques both in terms of software and hardware.
The Case for Power System Automation

- Reduce ground support personnel
- Alleviate downlink communications requirements
- Provide greater crew availability for mission support
- Effectively utilize resources for larger, more complex load configurations
- Reduced response times for reconfiguration after faults
Circuit breakers are very effective at quickly safing a power system. They represent the only technology available which can react in time and also be remotely controlled and monitored. Though conceivably a very fast computer could read sensors, recognize high current, and order a switch open before damage could occur, it is unlikely with today's technology, less reliable than circuit breakers, and offers no advantage over a remotely switchable circuit breaker.

Knowledge of the actual state of a system is necessary for effective control. Determining sensor locations and designing them into the system, instead of adding them on later, reduces the cost and increasing the reliability of the system as a whole.

A problem with numerous sensors is the flood of data they produce. What does one do with it? The answer proposed here is to sort it out locally, and only pass up summaries unless more is needed. Often "situation nominal" is much more relevant than a stream of data, no matter how accurate.

The central controllers act as an interface for human users, put system in an acceptable state if a problem occurs, assist users in identifying and correcting problems, record and allow modification of the system configuration, and provide the lowest level processors the data they need for normal operation.
SSM/PMAD Approach to Automation

- Use fast, simple, dependable hardware at the lowest level as the "first line of defense".
- Provide adequate sensors to understand the system state.
- Distribute processors through the system to control low level hardware, gather sensor data, and communicate with higher level control.
- Coordinate system-wide activity through intelligent controllers.
The Space Station Module Power Management and Distribution (SSM/PMAD) test bed has been established at MSFC through the space station advanced development funding starting in 1985. Subsequent automation upgrades and improvements have been realized through space station evolutionary funding and OAST participation. The test bed is currently supporting advanced automation activities as well as prime space station development testing.
SSM/PMAD Test Bed

- Test bed emulating the hab/lab Power Distribution and Control architecture
- Started under Advanced Development -- 1985 -- Hardware and Automation contracts to Martin Marietta Aerospace
- Presently funded by Codes SS, ST, and RC
- Original configuration for 20kHz with ring bus primary distribution modified for 120V DC and radial distribution
The topology of the SSM/PMAD is the same as for the present space station baseline design. The primary power distribution assembly (PDCU) redistributes 120 VDC power to each of up to six rack load center locations through 3kw remote power controllers (RPC). The power is then fed to the loads through 1 or 3 kw RPCs within the rack. Each rack load center and PDCU is controlled by a dedicated lowest level processor (LLP). The overall test bed control is done by the Symbolics 3620 D and the Unix workstations. The space station module topology identifies the PDCU as a secondary power distribution assembly and the rack load center as a tertiary power distribution assembly, but the functions these elements perform are identical. The control architecture of the test bed is similar to that baseline for the space station. This similarities will be discussed later.
As part of the automation development approach to the SSM/PMAD, a function partitioning of the module PMAD was conducted. This was conducted in four steps: (1) list and define potential types of controlling entities for functions; (2) develop rules and guidelines to partition functions; (3) define PMAD to sufficient level of functional detail to allow partitioning of single controlling entity to each function; and (4) partition controlling entities/definitions of (1) to each function defined in (3) using rules and guidelines of step (2).

Controlling entities are hardware (settable but not programmable in the usual sense), algorithmic software (conventional software), expert system (incorporating knowledge, experience, and problem solving approach of human experts), crew partition (controlled by onboard and/or ground support personnel), and expert-aided crew (same as crew except the person(s) are aided by expert system or by outside expert person).

The partitioning rules pertain to function types categorized as simple (well understood functions/processes such as simple mathematics/logic with predictable inputs and outputs), complex (technically understood functions using knowledge from accepted text books/procedures, but requiring advanced scientific skills or training to implement), and expert (functions usually understood only by recognized experts and requiring their knowledge and judgment to implement).

Definition of the SSM/PMAD task was accomplished by mapping a functional breakdown of the PMAD task. Power Management & Distribution was broken down into power conditioning, power distribution, and power network control. Each of these in turn was broken down into three or four divisions. The power network control divisions were broken down into two deeper layers.

The Power Network Control functions, provisionally assumed to require software development were then evaluated. Determination of which subfunctions could be controlled entirely by a single type of controlling entity were followed by an estimation of the necessary capability or complexity of each subfunction. This was followed by first order estimates of the difficulty of developing the software necessary to control the subfunctions.

Finally, the actual partitioning of the entire SSM/PMAD task was performed. Tables were developed to follow the functional breakdown partitioning rules and software development estimates.
Functional Partitioning

FUNCTION PARTITIONING

- DEVELOPED 26 RULES FOR FUNCTION PARTITIONING OF SSM/PMAD

Marshall Space Flight Center
This viewgraph shows the control logic flow of the SSM/PMAD. Control operations which must be performed as quickly as possible to prevent damage to the power system (immediate) are done in the hardware, i.e., various abnormal operating modes as discussed in the following RPC description. Functions requiring response times in the seconds or tens of seconds, or which are not time critical can be performed at appropriately higher levels. However, it is still desirable to perform power system control at as low a level as possible to minimize dependency on global type communication networks.

Marshall Space Flight Center
Rack Level Autonomy -- Switches, Sensors, LLPs, and CAC

The RPCs designed for this breadboard actually consist of two parts: a power stage, which is a switch with resetable over-current protection and a current sensor, and a Generic Card (GC). The GC uses a state machine to offer protection against various abnormal conditions, and to communicate with the Switch Interface Card (SIC) and the power stage. Individual sensors are attached to an A-to-D converter which is also attached to the SIC. Each Lowest Level Processor (LLP) communicates with up to two SICs in a Load Center -- one for each bus.

The LLP turns RPCs on or off according to a schedule downloaded to it. It also monitors all the sensors and RPCs. If an RPC trips, the LLP notifies FRAMES of the kind of trip as part of a full status update. The LLP performs in the same way if an RPC is using more power than it is scheduled for, even if the level wouldn't trip the RPC. The LLP orders that RPC off and reports the fault. If the schedule marks an RPC as redundant, the LLP will attempt to turn on a load's redundant RPC if the primary one trips or is shed. Finally, the LLP stores a priority list for it's loads so, in the event of a reduction in system power, lower priority loads will be shed first.

The Communications and Algorithmic Controller (CAC) acts as the communications interface between the LLPs and the higher level controllers. It is the central control point in manual mode operation.
Rack Level Autonomy

- Remote Power Controllers (RPCs) provide immediate protection.
- RPCs are grouped into Load Centers. Load Centers are controlled by Lowest Level Processors (LLPs).
- LLPs execute a schedule which is downloaded to them.
- LLPs shed loads which use more than scheduled power.
- LLPs can switch loads to the secondary bus when necessary.
- LLPs communicate with higher level controllers through the CAC.
Testing in the SSM/PMAD has shown that current limiting capability at the load center level can in fact help in preventing the propagation of faults to other loads within the rack or to the distribution bus. Including protection against as many abnormal operational circumstances as possible can facilitate isolation of faults and hence increase power system reliability for other loads. Pre-reduction of data at the switch level can alleviate processor communication delays. A "smart", current limiting RPC with the characteristics shown on the vugraph and capable of protecting against several fault modes has been developed for the SSM/PMAD. A similar version was also developed for use in the 20kHz version of the SSM/PMAD.

Fault Recovery and Management Expert System (FRAMES)

FRAMES is one of the three AI systems in the SSM/PMAD breadboard. Each LLP notifies FRAMES any time it recognizes an anomaly, such as tripped breakers or shed loads. Messages giving sensor readings are also sent to FRAMES. FRAMES uses the information which comes to it to characterize the system state. If a failure is diagnosed, it notifies the user via its user interface, and sends a message to Maestro, the system scheduler. Components are marked failed if it is believed they are broken, or out-of-service if they are not usable (e.g. a circuit-breaker above is failed). This information is passed on to Maestro for use in rescheduling.

The FRAMES user interface shows the whole system state. Every switch and sensor in the system is displayed, and shows whether or not it is powered, failed, or out-of-service. Switches also show whether they are opened, closed, or tripped. Components are mousable for further information, including sensor values and values of various flags.
Frames

- Monitors breadboard, reporting anomalies to user and to Maestro.
- Evaluates anomalies to determine if failure has occurred, and diagnoses failure based on reported symptoms.
- Notifies user and other expert systems of conclusions, including any switches considered out of service.
- User interface allows examination of breadboard sensor reading and switch statuses.
- Uses rules developed through work with Power Engineers.
- Coordinate system-wide activity through intelligent controllers.

Maestro

Maestro is a resource scheduler which can schedule numerous activities using multiple constraints. In the SSM/PMAD breadboard the constraints currently used include number of crew members required, equipment resources, and power resources. Power is allocated not just by how much is available to the whole system, but also by the ability of intervening components to supply the power.

Maestro's interface converts the schedule into a list at the component level. Information includes start and stop times and upper and lower power levels at each component.

Dynamic rescheduling may be done in the event of a fault. Maestro has access to Activity, Schedule, and Equipment Libraries, and uses encoded knowledge gained from expert schedulers to schedule within constraints.

Load Priority List Management System (LPLMS)

The third of the AI systems, the Load Priority List Maintenance System (LPLMS) uses information from the event list and the activity library, along with its own rules, to dynamically assign relative priority to each active load in the system. A new list is sent down to the LLPs at least every 15 minutes (less than 15 if a contingency occurs). The load priority list can be used to shed loads in case of a reduction in power.
Planning/Scheduling

MAESTRO

- Schedules all SSM/PMAD load for crew period (and longer) based on need/availability of resources
- Resources include available power, distribution system capacity, crew members needed, equipment, etc.
- Enables operation during contingencies until new baseline schedule is generated
- Tracks and accommodates PMAD configuration changes
- Reduced response times for reconfiguration after faults

Loads Priority List Management System (LPLMS)

- Handles dynamic priorities of up to 500 loads
- Generates global load shedding list every 15 minutes

This chart compares the control of the SSM/PMAD (as described previously) with the Space Station Freedom baseline. The basic levels of control are essentially the same for the SSM/PMAD and Space Station Freedom baseline. One major goal of the advanced automation task is to transfer FDIR (fault detection, isolation, and recovery) to a module level controller, thereby eliminating need for significant involvement of crew and/or ground personnel. In addition, control, contingency, and reconfigurations functions are migrated to lower levels as part of the advanced automation tasks. Advanced automation will also permit a much larger portion of scheduling the onboard short term plan (OSTP) to actually be done onboard. The cost of these advances is increased processing capability. At present, the Space Station Freedom lab module baseline provides only 15 controller MDMs to control approximately 29 active rack locations (although this number will be increased to one controller MDM in each rack at assembly complete).

Planned Modifications to SSM/PMAD

By the middle of 1990, some fairly major changes to the automation portion of the SSM/PMAD should be in place. These include a new unix-based computer to host both the FRAMES and CAC functions, 80386 computers with Ethernet to replace the current LLP processors, and some major changes in the structure of FRAMES, with it rehosted in a powerful Knowledge Base Management System environment. The user interface will be significantly upgraded, also.

Under OAST funding, research is under way in how to improve cooperation among the three expert systems, and in adding intermediate modes of autonomy. In the current system, the user has the choice of autonomous operation, or of taking over the whole system. The intermediate modes will provide choices between these two extremes, so a user can have the help of an intelligent assistant.

As the system matures and stabilizes, portions will be transferred into the Ada language, running on general purpose processors. Stricter validation and verification will be observed than is desirable in the present prototypical phase. At the close of this phase, the system should be mature enough to be moved into the mainstream of the Space Station Freedom Program.
SSM/PMAD

Ongoing Enhancement to SSM/PMAD

- Upgrade of communications (Ethernet)
- Expansion of Intermediate Levels of Autonomy
- Consolidated, improved user interface
- Upgrade FRAMES Knowledge Base Management System
- Operation with LeRC Automation Test Bed
Proposed MSFC/LeRC Communications

A communications link is now available between MSFC’s AMPSLAB facility, which includes the SSM/PMAD breadboard, and the Lewis Research Center Power Technology Division laboratory, with their Autonomous Power Expert System (APEX). Two virtual links are envisioned between the two PMAD systems.

The first link will involve the schedulers for the two systems. Initially interaction will be limited to a request for some level of power from SSM/PMAD for each of the two power buses. APEX would then assign levels, possibly different from those requested, for the buses. As the systems mature, the negotiation will become more sophisticated; SSM/PMAD will provide justification for its request, and APEX will be expected to compare SSM/PMAD’s request with those from its other loads to provide an overall "fair" schedule according to balanced priorities.

The second proposed link will be between one of the loads on the APEX brassboard and one of the dc sources on the SSM/PMAD system. The power drawn by the load will be varied to reflect the power being used in the SSM/PMAD breadboard, thus emulating a single end-to-end power system.

The actual communications link between the centers is via TCP/IP using the PSCN-1 service. Both virtual links will be built on this connection, though the second connection may initially be done manually, with communication by telephone.
MSFC/LeRC Communications

- A virtual link between the intelligent controllers allows negotiation for power resources.
- A second virtual link between one of the LeRC load and a MSFC source allows emulation of a single breadboard.
- Each breadboard can still be operated independently.
- The actual communications link is available using TCP/IP on the PSCN-I.
The primary technology drivers which need to be addressed to allow progress towards full automation of the module electrical power system are summarized.
Future Technology Needs for Power System Automation

- Develop cooperating expert systems
- Automation techniques for:
  - Larger, more complex systems
  - Handle Incipient Failures
  - Perform FDIR for multiple, independent failures
- Improve user-oriented explanation/ interface facilities
- Refinement of Algorithms & Rules
- Improved Sensors/Switches:
  - Accuracy/Reliability
  - Data Reduction
  - Fault Analysis
- Increase DMS capability:
  - Reduce Power
  - Permit More Processing Capability
  - Reduce Latency

SPACE STATION PROPULSION SYSTEM REQUIREMENTS

There are several requirements that the Space Station Propulsion System has to meet. The Propulsion System for the Station is no different from most other propulsion systems in that it is required to provide thrust for attitude control torques and translation maneuvers. Since primary attitude control is done via Control Moment Gyro’s (CMG’s), the Propulsion System will only be used for damping disturbances which exceed the CMG’s capability, for desaturation of the CMG’s and for CMG back-up. The translation requirements are for compensation of atmospheric drag (reboost), orbit altitude adjustment which might be necessary, and collision avoidance. By far the biggest propulsion requirement is for reboost, which will consume, on average, approximately 2.8 million lbf-sec of impulse per year, which represents over 95% of the propellant required.

Other propulsion requirements are to utilize waste fluids to produce useful impulse and to maintain sufficient propellant reserves, such that if a resupply is missed, the Station can still perform nominal operations.
SPACE STATION PROPULSION SYSTEM

SPACE STATION PROPULSION SYSTEM REQUIREMENTS

- PROVIDE THRUST FOR:
  - ATTITUDE CONTROL
    - LARGE DISTURBANCE DAMPING
    - CMG DESATURATION
    - CMG BACK-UP
  - TRANSLATION
    - ATMOSPHERIC DRAG MAKE-UP (REBOOST)
    - ORBIT ALTITUDE ADJUSTMENTS
    - COLLISION AVOIDANCE

- UTILIZE WASTE FLUIDS TO PRODUCE USEFUL REBOOST IMPULSE

- MAINTAIN SUFFICIENT PROPELLANT RESERVES IN THE EVENT OF A MISSED RESUPPLY
SPACE STATION PROPULSION CONFIGURATION

The Propulsion System modules are located above and below the transverse boom at each end. At each location, there are two module interfaces, such that two modules can be sitting side by side. This is done so that one of the modules can be completely depleted prior to being removed from the Station, and the remaining module can be activated, so that there is no loss of propulsion capability.

PORT LOWER PROPULSION MODULE

FRONT VIEW
SPACE STATION PROPULSION SYSTEM DESIGN

During the "Scrub '89" exercise, the Space Station Propulsion System design was changed from a Water Electrolysis/Oxygen-Hydrogen system to a modular hydrazine system. The change was made to reduce the risk to the program and to reduce the up-front development costs. A blowdown hydrazine system was baselined because of the simplicity of the system and the maturity of the system hardware. Hundreds of satellites have been constructed and flown with blowdown hydrazine systems. GN&C is concerned about the variation of thrust between modules and the complexity of the software to control and target the Station.

The Propulsion System concept is as follows: At each end of the transverse boom are two propulsion locations, one each above and below the boom. At each of the propulsion locations, there are two module interfaces, such that two modules can be collocated next to each other. When one of the modules is depleted of propellant, it is returned to the ground and the adjacent module is utilized. The modules are propulsion systems, containing everything that is required to produce thrust: propellant tanks, isolation valves, thrusters, heaters, instrumentation and avionics. The only interface with the truss is with power, data and structural interfaces. There are no fluid connections which can be mated on-orbit. In this way concerns over propellant spillage and leakage is minimized. All maintenance on the system is done only on the ground. Because of the Station Critical requirement for performing reboost, each module is dual fault tolerant.

Preliminary Propulsion Module Configuration

The Propulsion Module consists of all of the hardware required to meet the Station requirements: propellant tanks, isolation valves, attitude control thrusters, reboost thrusters, avionics, thermal control, etc. It is designed to fit in the Orbiter Payload Bay.
(8) 36.0 DIAMETER STD LENGTH MK II TANK CONFIGURATION
SPACE STATION PROPULSION SYSTEM DRIVERS

The Propulsion System design is driven by many external factors. Here is a short list of the most important parameters:

1) The Space Station is not going to be maintained at a fixed altitude, but rather will be allowed to vary in altitude such that the Orbiter Logistics can be optimized, while maintaining adequate Station Orbit life-time. This orbit altitude is a function of Station Configuration (Mass and Frontal area) and also the atmospheric density, which varies with the eleven year solar cycle. Because of these considerations, the Propulsion System impulse requirement is a function of the Orbiter capability, overall Station configuration and the atmospheric density.

2) The Propulsion System thrusters were sized to 25 lbf each back when the Station was staying at 270 nmi constant altitude, which meant that the reboost impulse was much less than it is today. When the altitude strategy was changed to the variable altitude strategy, the burn times for performing reboots increased significantly. An average reboost with four 25 lbf thrusters takes about 2 hours to perform. The maximum reboost takes over four hours to perform. With a modular blowdown hydrazine system, thrusters are not available 'off-the-shelf' for these burn times, and the reboots will only be done with two of the modules for propellant utilization purposes. This means that the thrust size for the reboost thrusters should be increased. There are structural concerns which are being worked. The attitude control thrusters would remain at 25 lbf.

3) Because the Station is operating lower in the atmosphere, the Propulsion System is required to keep the Station from re-entering. At times, the margin against re-entry is as little as 90 days. This means that the Propulsion System must be dual fault tolerant for station survival (i.e. reboost).

4) The requirement for propellant resupply introduces a set of requirements on the Propulsion System. The first is to optimize the package in the payload bay, both the mass and the volume. Since the capability of the Orbiter is fixed, the challenge is to design the module such that the most propellant is brought up in the lightest and smallest package. Since there will be other items being brought up to the Station at the same time as the Propulsion system is being resupplied, compatibility with those other elements (unpressurized logistics module, pressurized logistics module, etc.) is a design driver. Finally, since the modules will be flying routinely in the Orbiter Payload Bay, the safety requirements that are imposed on any other payload must be met by the Propulsion Modules.

HYDRAZINE TECHNOLOGY DEVELOPMENT

In order to minimize the number of thrusters required for each module, the capability of being able to deplete the entire module through a single reboost thruster is desirable. The current demonstrated through-put of hydrazine thrusters in the 100 lbf range is approximately 1 Million lb-secs (4300 lbm of propellant). If the modules contain 4500 lbm of hydrazine, then every time a module is reserviced, a thruster would have to be replaced. If the modules are bigger than this, then there would have to be additional thrusters or the life of the thrusters must be improved.

Because of the costs associated with installing additional thrusters, extending the life of hydrazine thrusters is being pursued. A supporting development program is progressing to modify existing designs and demonstrate additional thruster lifetime, with the goal of at least doubling the life of the thrusters. An RFP will be distributed soon with delivery of thrusters expected in the fall of 1990. These will then be tested at our test facility at JSC.

Other technology development programs may be necessary, depending on the final propulsion system configuration. Configurations which are being examined include systems with metering valves to provide a constant inlet pressure to the thruster from a blowdown system, a system with a pump and accumulator to provide a constant inlet pressure to the thrusters, or an electronic regulator for providing constant tank pressure. These configurations may be required due to concerns by GN&G over the potential thrust mismatch between propulsion modules.

WASTE FLUID DISPOSAL SYSTEM

The Waste Fluid Disposal System was the resistojet. However, during SCRUB '89, the power requirements for the resistojet were questioned. With this in mind, a trade study was initiated at the WP-02 contractor to determine the 'best' method of waste fluid disposal. The options are as follows:

1) Resistojet: Much advanced development has occurred on the resistojet, including work by in the late '60s-'early 70's by Marquardt and much more recent work by LeRC. The problem with the resistojet is that, depending on the flowrate and the temperature desired, up to 500 W are consumed per resistojet. With all six resistojets firing, the resistojet module would be consuming 3 KW of power, approximately 4% of the entire Station generating capability.

2) Waste gas disposal using Hydrazine thrusters: Work was done on this concept by Rocket Research during Phase B. The concept was demonstrated, however, additional work needs to be done to characterize the performance of the thruster when an oxidizing gas is introduced to the combustion chamber. It also has the disadvantage in that a consumable which must be re-supplied from the ground is consumed to heat the waste gases.

3) Thermal Energy Storage: This concept involves slowly heating a phase change material using low power heaters, and then passing the waste fluids through a heat exchanger to heat the gases. This concept would not have the instantaneous power consumption of the resistojets, but would probably consume more energy (low power for long periods of time) due to thermal losses. This concept also does not have a consumable which must be re-supplied.

The MDSSC trade study is expected to be completed in mid-February, 1990.

INTEGRATED SCHEDULE - PROPULSION SYSTEM

The Propulsion System Integrated Schedule shows the classical DDT&E approach to flight hardware: Preliminary Design, Detailed Design, Development Testing, Final Design, and Qualification Testing. Due to cost reasons, the Propulsion System Development and Qualification Testing will be done at the NASA-JSC White Sands Test Facility (WSTF).

The Supporting Development Schedule reflects the remaining work from the Water Electrolysis/Oxygen-Hydrogen System, the preparation of the WSTF facility for Development and Qualification testing, and the Long Life Hydrazine thruster effort.

SPACE STATION PROPULSION SYSTEM EVOLUTION

The choice of hydrazine for the long term Station means that the program will be paying a large life cycle cost for propellant resupply because of hydrazine's low specific impulse. Because of this, the WP-82 contractor has been tasked with performing a trade study to determine what Propulsion System should be used for the long term. Options include the present modular hydrazine system, a distributed hydrazine system, several bipropellant systems, and the old baseline, a distributed Water Electrolysis/Oxygen-Hydrogen system. All of the propellant combinations for the bipropellant system utilize Nitrogen Tetroxide (NTO) as the oxidizer. The fuels being considered are Monomethyl Hydrazine (MMH), Hydrazine, and a blend of 50% Unsymmetrical Di-Methyl Hydrazine (UDMH) and 50% hydrazine called A-50.

In addition to these propellant combinations, combinations of systems were included for study. Since the program is developing the modular hydrazine system, this system could be used for attitude control and contingency purposes, and a dedicated, high performance reboost system could be used for atmospheric drag compensation.

The trade study is expected to be completed by the end of January, 1990.

O VALVES

O THRUSTERS

O HIGH PRESSURE/LIGHT WEIGHT STORAGE VESSELS

O ELECTRONIC PRESSURE REGULATION

O SYSTEM LEVEL TESTING
This is a suggested technology plan that would be pursued if the Water Electrolysis/Oxygen - Hydrogen system is selected by the WP-02 contractor as the system of choice for the long term Station. This schedule includes electrolysis unit development, electrolysis component development, electronic regulator development, thruster testing and improvements, Graphite/Epoxy tank testing, and finally System level breadboard testing.

TECHNOLOGY NEEDS FOR BIPROPellant SYSTEMS

Even though bipropellant systems are "state of the art", additional development for on-orbit servicing of the system is required. Obviously, if the systems are going to be serviced on-orbit, the first component that needs to be developed is the automatic couplings for the transfer of hazardous fluids. Other technologies that require development are the capability to vent off the pressurant gas from the system (if the system is a pressure regulated system) without expelling liquid propellant. This could be accomplished by new zero-g liquid separation techniques or by the development of Oxidizer compatible diaphragms. Also, to make the refueling system as light at possible, transfer pumps could be developed.

The hydrazine/HTO system is attractive from the lack of carbon and carbon compounds in the thruster exhaust. If this is the system chosen, then considerable work still needs to be done on thrusters using this propellant combination.

One of the problems with HTO is the formation of iron nitrate. This problem can be eliminated by constructing the system only of titanium. One of the problems is that there are no titanium bellows for valves. This means that components being constructed using titanium contain bimetallic joints where materials containing iron are utilized. The development of titanium bellows is required for building a true all titanium system.

Finally, leakage of regulators over long periods of time has historically been a problem with space craft. This is why most systems flown are blowdown systems. In order to utilize a pressure regulated system for the bipropellants, regulator designs which can better handle contaminates and reaction products from the propellants need to be developed. The area of electronic pressure regulators means that high response and high seal loading can both be attained.
0 TECHNOLOGY NEEDS FOR BIPROPELLANT SYSTEMS

0 IF ON-ORBIT PROPULSION SYSTEMS SERVICING REQUIRED:

0 FLUID TRANSFER COUPLINGS
0 OXIDIZER DIAPHRAGMS
0 ZERO-G VENT CAPABILITY (LIQUID/VAPOR SEPARATION)
0 TRANSFER PUMPS (POTENTIAL)

0 HYDRAZINE/NTO THRUSTERS IF THAT PROPELLANT COMBINATION SELECTED

0 ALL-TITANIUM OXIDIZER SYSTEMS

0 TITANIUM BELLOWS

SPACE STATION PROPULSION INTEGRATED PROPULSION TEST ARTICLE
INTEGRATED PROPULSION TEST ARTICLE

At the end of Phase B, the baseline Propulsion System on the Space Station was a Water Electrolysis/Oxygen-Hydrogen (WEOH) system. The idea was to utilize the excess water from the Orbiter Fuel cells as the propellant. Add the fact that Oxygen/Hydrogen has a high specific impulse and the resupply quantities for the Station are greatly reduced. However, with the newer altitude strategies, and the overall water balance on the Station, it appears that a considerable amount of water would have to be resupplied.

Because of the lack of advanced development on the WEOH system, JSC embarked on a test program called the Integrated Propulsion Test Article (IPTA). Started in 1987, this system consisted of a 3000 psi electrolysis unit, high pressure (3000 psi) gas storage, electronic pressure regulation and available thrusters. Phase I testing began in 1988 and consisted of end-to-end system operation demonstration, proving the feasibility of the WEOH concept.

Phase II testing will utilize much of the Phase I test hardware, but will be configured to better simulate the envisioned Space Station distributed system. Testing is to begin in April, 1990.

In addition to the system demonstration, contracts are on-going in the area of high pressure electrolysis units.
SPACE STATION BASELINE WAS A WATER ELECTROLYSIS/OXYGEN–HYDROGEN SYSTEM

- UTILIZE 'WASTE' WATER FROM THE ORBITER FUEL CELLS
- HIGH SPECIFIC IMPULSE PROPELLANT COMBINATION

INTEGRATED PROPULSION TEST ARTICLE FIRST TESTED IN 1988

- INTEGRATED BREADBOARD SYSTEM USING AVAILABLE HARDWARE
  - HIGH PRESSURE ELECTROLYSIS UNIT (3000 PSI)
  - ELECTRONIC PRESSURE REGULATION
  - ROCKETDYNE AND BELL THRUSTERS

PHASE I DEMONSTRATED END-TO-END SYSTEM OPERATION

- WATER IN - THRUST OUT

PHASE II TO DEMONSTRATE OPERATION WITH SYSTEM MORE CLOSELY RESEMBLING THE PROPOSED SPACE STATION CONFIGURATION

- PHASE II TESTING TO BEGIN IN APRIL, 1990

ELECTROLYSIS UNIT DEVELOPMENT
PHASE I CONFIGURATION DESCRIPTION

The Phase I IPTA consisted of a high pressure electrolysis unit, high pressure gas storage tanks, electronic pressure regulation, and available thrusters. The electrolysis unit was a unit borrowed from the Navy called the Oxygen Generation Plant (OGP). This unit was a development test article which has accumulated many hours of run time. It is used to generate Oxygen at high pressure (3000 psi). With very little modification, it successfully generated both hydrogen and oxygen for storage in high pressure tanks, and subsequent usage in the thrusters.

Electronic regulators were procured from Marotta for control of the gas flow rates. This is required due to potential temperature differences between the oxygen and hydrogen. They can also be used to vary the thrust and also to maintain or vary the O/F ratio being delivered to the thruster.

Available thrusters were used for Phase I testing. Two thrusters were tested: a Bell thruster which was originally built for a LeRC contract, and an IRAD thruster from Rocketdyne.
## PHASE I CONFIGURATION DESCRIPTION

### ELECTROLYSIS UNIT

- NAVY OXYGEN GENERATION PLANT (OGP)
  - 3000 PSI OPERATION
  - DEVELOPMENT UNIT

### ELECTRONIC REGULATORS

- Capable of varying inlet pressure to thrusters to compensate for:
  - Temperature variations
  - Thrust selection
  - Desired O/F ratio

### THRUSTERS EVALUATED

- BELL – LEWIS CONTRACTED THRUSTER
- ROCKETDYNE – IRAD THRUSTER ON LOAN TO JSC
Phase II testing will demonstrate the envisioned Space Station configuration. Long distribution lines between the high pressure gas storage and thrusters are being installed. The capability to fire multiple thrusters is being built into the test article so that system dynamics can be studied. Thermal conditioning of the propellants to simulate long thruster firings and determine the effect of varying the thruster inlet temperature and pressure will be an additional capability.

The propellant storage capacity will also be increased so that longer thruster firings can be performed. Electronic pressure regulation will be installed upstream of the distribution lines to simulate the planned Station configuration. Finally, as the new breadboard electrolysis units become available, they will be installed in the IPTA to determine system compatibility and concerns.

When testing resumes, we will have the capability of operating a WEOH breadboard system which closely simulates the envisioned Space Station configuration over a wide range of operating conditions.
0 PHASE II TESTING

0 RECONFIGURE TEST ARTICLE

0 LONG DISTRIBUTION LINES

0 MULTIPLE THRUSTERS

0 THERMAL CONDITIONING OF PROPELLANT

0 LARGER PROPELLANT CAPACITY

0 ELECTRONIC REGULATION TO CONTROL DISTRIBUTION PRESSURE IN ADDITION TO THRUSTER INLET PRESSURE

0 BREADBOARD ELECTROLYSIS UNIT AS IT BECOMES AVAILABLE

0 TESTING TO DEMONSTRATE OPERATION OF A SYSTEM CLOSER RESEMBLING THE STATION CONFIGURATION OVER A LARGE OPERATING RANGE
Contract were let in 1988 to two electrolysis unit manufacturers to develop breadboard high pressure electrolysis units. The two manufacturers are developing two different technologies, Hamilton Standard is modifying their OCP technology for space applications (lower weight, smaller packaging, etc) which utilizes a Solid Polymer Electrolyte, and Life Systems, Inc is developing an Static Vapor Feed unit. The delivery of the first unit is expected in March, 1990.

The delivered unit will consist of the cell stack and all necessary hardware to operate the unit at 3000 psi. Extensive testing is planned for the units at JSC following delivery. Stand-alone testing will demonstrate the operational characteristics of the particular device. And then the unit will be installed in the IPTA to demonstrate system operation.
ELECTROLYSIS UNIT DEVELOPMENT CONTRACTS AWARDED IN 1988

PARALLEL DEVELOPMENT OF TWO HIGH PRESSURE ELECTROLYSIS TECHNOLOGIES

- ACID CELL/SOLID POLYMER ELECTROLITE - HAMILTON STANDARD
- ALKALINE CELL/STATIC VAPOR FEED - LIFE SYSTEMS, INC.

DELIVERY OF THE FIRST BREADBOARD UNIT IS EXPECTED BY MID-MARCH

HARDWARE WILL CONSIST OF CELL STACK AND ALL NECESSARY HARDWARE TO OPERATE THE UNIT

EXTENSIVE TESTING PLANNED AT JSC FOLLOWING HARDWARE DELIVERY

- STAND-ALONE TESTING
  - DEMONSTRATE OPERATIONAL CHARACTERISTICS
- IPTA TESTING
  - DEMONSTRATE SYSTEM OPERATION

SPE FUEL CELL/ELECTROLYZER FEATURES

• No free corrosive liquid - sole electrolyte is solid sheet of sulfonated fluoropolymer similar to teflon
  - Normality is fixed - cannot change with operating conditions or life - cannot be diluted by product or process water
  - Location & volume of electrolyte are fixed - cannot leak, creep, leach out or be expelled by acceleration forces or pressure differentials
  - Membrane forms rugged barrier separating reactants - tested to 5000 psid without blow-through

• >10 year life demonstrated with stable performance
  - >100,000 load hrs completed on electrolysis cells, >60,000 hr on fuel cell stack
  - < 1 μv/hr degradation
  - Fuel cell operates on commercial grade reactants
  - No carbonate formation

• Excellent load following - similar to a battery
SPE FUEL CELL/ ELECTROLYZER FEATURES (Cont'd)

- Simplified cell construction
  - Low cost
  - High yield with consistent performance
  - High reliability

- Mature technology with extensive hardware experience
  - Two successful space power applications
  - SPE electrolyzers in production for military and commercial applications
  - 30 years of development, manufacturing and operational experience
  - Technology status results from cumulative development funding from many programs

MSS Data Distribution and Interfaces
Functional Requirements for SPDM

Perform Dextrous Tasks for Assembly & Maintenance of:

- Mobile Servicing Centre, including Mobile Transporter
- External Space Station Systems
  - Power System
  - Alpha & Beta Gimbals
  - C&T System
  - GN&C System
  - DMS System
  - RCS
  - SIA and PIA (for attached payloads)

Perform Dextrous Tasks for

- Handling Small Payloads (external)
- EVA-Support
- Safe Haven Support
Functional Requirements for SPDM (cont’d)

Dextrous Tasks for Assembly and Maintenance include

- Exchange ORU’S
- Attach / Detach ORU Interfaces
- Connect / Disconnect Utilities
- Mate / Demate Connectors
- Remove / Install Thermal Covers & Blankets
- Clean Surfaces
- Inspect and Monitor with Vision System
- Provide Lighting to Support EVA
- Position Tools & Materials to Support EVA
- Provide TV Views to Monitor EVA Activities

- MT - Mobile Transporter
- PMC - Permanently Manned Configuration
- SPDM - Special Purpose Dextrous Manipulator
- SS - Space Station
Objective of Advanced Technology Development

- Minimize crew workload
  - Automate all routine operations and mundane tasks
  - Develop a hierarchical command structure; evolutionary shifting of control functions from operator to machine
  - Automate monitoring of operations; crew intervention only when alarms occur
  - Improve Human–Machine interfaces

- Increase autonomy and minimize ground support of MSS operations
  - Improved on–orbit access to design data, maintenance procedures, test procedures and archived operational data.
  - Tools for on–orbit planning of MSS operations.

- Increase the operational effectiveness of the MSS.
Basic Requirements for Advanced Technology

- Focused effort in selected areas
  - Application specific
  - Probable success
- Modular and add-on type concepts
- At the completion of proof-of-principle demonstration (POPD) concepts proceed along the MSS Program life-cycle
- Compatibility between MSS and Space Station A&R concepts
  - Commonality
  - Effective utilization of station resources
- Evolutionary approach
- Future growth
- Technology transparency
- Progressive evolution from teleoperation towards autonomous operation
Automation and Robotics Technologies
MSS Baseline

Target-Based Vision
- position, orientation, rate determination

Collision Avoidance
- collision warning

Force/Moment Accommodation
- limiting of applied forces and torques
Automation and Robotics Technologies
MSS Baseline (cont.)

Coordinated Control
- two manipulators
- SSRMS/SPDM

Command Language
- hierarchical
- object-oriented
- extensible

Achievable Level of Automation
- auto-trajectories
- automated tracking and grappling
Automation and Robotics Technologies
Planned for Incorporation

Enhanced Vision System
- depth recovery
- shape recognition
- object recognition

Collision Avoidance
- machine assisted trajectory planning
- on-line trajectory management
Automation and Robotics Technologies

AGENT-INDEPENDENT PLANNING

Presenter: Bill Davis

Organization: Boeing Computer Services
Artificial Intelligence Center
P.O. Box 240002, MS JA-74
Huntsville, AL 35824-6402
(205) 461-2348
email: bill@huntsai.boeing.com

Session: Robotics

Technology for
Space Station Evolution
Workshop
Section: Introduction
Title: Definitions

1. Defining "Agent-Independent Planning"

"Agent-Independent Planning" is a method of automated planning that allows the generation of task plans from a set of goals, without having to be concerned with constraints imposed by the agent that will execute the plan. In the domain of Space Station Freedom (SSF), these plans can be considered a sequence of tasks for intra-vehicular and extra-vehicular operations activity. Plans, or operations procedures, are developed by considering general constraints on the planning environment and task sequences. For execution of these procedures, the plans are translated into the specific operations language of a particular agent. This methodology allows plans and their environment to be modeled in a fashion that separates different classes of constraints into independent sets.

2. Defining "Agent"

An "agent" is any entity that will perform the plan. Again, in the domain of Space Station Freedom, an agent might be a crewmember, robot, or some automated system. Each of these agents has a unique set of instructions which it understands, whether English sentences, robotic programming commands, or software instructions. Each agent also has its own set of capabilities and constraints when executing a plan. These constraints are modeled and used independently from general planning constraints. The key benefit from this methodology in that these operations procedures may be developed virtually independently from robotic/automated systems or crew skills necessary to execute them. This allows systems to be developed without changes in one component adversely impacting another.
Definitions

**Question:** What is agent-independent planning?

**Answer:** Constructing plans to satisfy a set of goals, regardless of the agent that will perform them.

**Question:** What is an agent?

**Answer:** Any entity that effects action on the environment. Includes:

- Robots
- Crewmembers
- Automated Systems (software & hardware)

**Key Benefit:** Development of procedures is *independent* from development of robotics / automation / crew skills to perform them.
Section: Motivation

Title: Space Station Freedom Robotics Environment

1. Different Kinds of Robotic System Implies Redundant Programming

The number of ways to automate a single task through robotics is proportional to the number of robotic systems. That is, to direct different robots to do the same task would likely require a different software program for each robot. Suppose an robot on board of SSF had been programmed to remove certain types of pumps from a rack. If that robot were replaced with a new robot of increased capability, this new robot would likely require fresh programming to perform the same pump removal tasks. While this problem of redundant programming is not unique to the domain of Space Station Freedom, it is intensified under the new challenges associated with its long life cycle (30 years).

2. New Challenges Created By SSF Life Cycle

The long period of planned station operation poses significant challenges to integrating advanced technology. The primary concern is the evolution of technology over this extended life cycle. This evolution will realize a continuous set of upgrades in robotic capabilities, including greater precision of robotic movement, increased dexterity of robotic manipulators, and advanced capabilities in vision, force, range, and other sensors. Similarly, operations procedures will evolve through continuous additions and modifications, increasing the range of workload for the crew. However, crew time for intra-vehicular and extra-vehicular activity will certainly remain a resource of great expense. These conditions will enhance the potential to offset some of this expanding workload from crewmembers to robots, particular as the advent of increased robotic capabilities allows them to perform more advanced operations. Hence, we are faced with a changing set of operations procedures, a changing set of robots to perform them, and the challenge of maintaining their integration.
Space Station Freedom long life cycle creates new challenges:

- Evolving technology
- Continuous set of upgrades in robotics
  - greater precision
  - increased dexterity
  - advanced sensor abilities
- Continuous additions to SSF operations
- Extremely high cost of intra- and extra-vehicular activity

As technology advances, great potential exists to transfer expanding workload from crew to new robotic/automated systems.
Section: Motivation

Title: Transition from Crewmember to Robots

1. Maintaining Integration Between Crew, Robots, and Procedures

The transfer of workload from crewmembers to robots must be performed in a safe, consistent, and robust manner. Certainly robots (and their programming) must be verified as capable of safely performing the transferred work. Also, it must be verified that exactly the same operations are accomplished, whether performed by crew or robot. With advancing technology producing upgraded robotic capabilities, it is reasonable to predict the transfer of workload not only from crew to robots, but also from robots to robots. This transfer must maintain a robust integration with crew and procedures, such that problem of redundant programming does not impact system development.

2. Transition Table

Certain transition needs imply specific aspects of an approach to satisfy the requirements of a safe, consistent and robust system. Activities which require skills only possessed by humans may be transferred to robots as their capabilities increase. To maintain consistent and robust development of operations procedures, these activities must be modeled in a representation which can be applied to both crew and robots. Similarly, plans that are developed for execution by robots of one set of capabilities should remain applicable to robots possessing advanced capabilities. In order to apply these plans across robotic platforms, procedures must be represented separately from constraints imposed by capabilities of particular robotic systems. Given a system that can construct plans for robots with varying capabilities, it follows that this system should also be able to apply plans to crewmembers with varying skills.

In general, modeling operations procedures and their environment separately from robotic or crew agents allows the development of operations plans free from impact by changing robotic capabilities or crew skills. Agent-Independent Planning provides a facility for this robust development of both agents and operations plans. The approach used by this methodology allows plans to be generated and later validated for execution by any agent that is modeled in the system.
Need to maintain the transition from crewmembers to robotics systems in a manner that is **safe, consistent, and robust**.

Agent-Independent Planning can model and generate an operations plan and validate its execution for an array of robotic, human, or software agents.
Section: Approach
Title: Agent-Independent Planning System Flow

1. Generation

Plans for operations procedures are modeled and stored in a task library. Operations' tasks are represented through hierarchical abstraction, with each task decomposing into a network of lower-level tasks. Temporal logic operators connect the nodes of this network and represent the time relationships among the tasks. Temporal and nonlinear planning techniques combine tasks from the task library with objects in the planning environment to formulate a viable sequence of procedures to satisfy the operations goals. This plan considers only the constraints associated with objects and the temporal relationships among tasks.

2. Validation

An agent-independent plan is transformed into an agent-dependent plan by matching the constraints already present among tasks and object in the plan with those of a given agent. An agent's physical constraints are validated with respect to the physical constraints of the objects it must manipulate. An agent's functional constraints are validated with respect to the tasks and their temporal constraints. In essence, this validation declares whether the agent is capable of performing the given plan.

3. Translation

Once a plan has been tailored for a particular agent, the tasks of this plan can be broken down to the primitive-level tasks; that is, those with no further decomposition. Using the model from the agent knowledge base, these primitive level tasks are translated into specific instructions for the agent. For crewmembers, these instructions are English sentences composing crew activity plans. For robots, these instructions are the programming language of the robot controller, or robot system software commands. For an automated software system, such as a graphic simulator, these instructions correlate to a set of software commands to drive the automation. It is these primitive tasks, however, that provide a layer of independence between agent-independent plan and agent-specific instructions.

Title: Independence Between Plans and Agents

1. Motion Primitives and Modeling

The non-decomposable tasks, or primitive tasks, provide the common interface between agents and the planning environment. For our work in robotic applications, a small set of these primitives has been established that describe physical motion (move, push, pull, grasp, release, rotate etc.). Models of the planning environment (whether agents, object, or tasks) all relate to this set of primitives. The agents' and objects' physical and functional constraints are represented in terms of pre-conditions and effects on these primitive tasks. Object-oriented models of agent and object properties allows descriptions of agents and objects to be combined through inheritance.

For each primitive task, an agent model contains an appropriate set of instructions for the execution of that task. Primitive tasks are hierarchically abstracted into more natural concepts, allowing plans to be developed to an appropriate level for crewmembers, but remain decomposable into robotic instructions. The preconditions and effects associated with the primitive tasks are also abstracted to provide constraints for nonlinear planning techniques. Temporal logic operators which form networks among the abstractions are used in temporal planning to generate all viable "sequences" (whether parallel or sequential activity) for plan execution.
Independence is achieved by establishing a common interface between agents and their environment. In terms of robotics, this interface is action (physical motion).

**Motion Primitives**

Section: Status
Title: Current Testbed

1. Intelligent Planner

A system has been developed in Common Lisp on a Texas Instruments Explorer workstation which models, generates, validates, and translates plans for maintenance and repair operations to be performed in a rack-like environment by crewmembers, robots, and a graphic robotic simulator. Separate knowledge bases describe agents, objects, and the plan (task) library. Agents and objects are modeled according to classes of their capabilities. For example, a class of objects which require power to be disabled before manipulation by an agent can universally impose a power constraint on all its members. Such class representation allows inheritance of groups of constraints by merely having membership in the appropriate class. A more detailed discussion of this work can be found in:

2. Agents

A PUMA 560 robot possessing vision, force/torque, and tactile sensors receives plans in a language mostly consisting of VAL II controller commands. The sensors are used for safety in plan execution by detecting force thresholds on sensitive objects and potential object collisions in the planning environment. A graphical robotic simulator models the racks and their objects along with various robotic agents. This simulator maintains the inverse kinematics for the given agent and simulates its behavior of issued commands. It currently models both one- and two-armed PUMA robots to verify the dynamic translation capabilities of the planner. The planner generates sequential instructions for the one-armed agent, whereas parallel instructions are produced for the two-armed agent. The planner also generates sets of English sentences describing operations activities. These plans are issued to a crewmember using a DecTalk speech synthesis system, with the crewmember providing feedback to the planner through a Verbex voice recognizer.
Existing Testbed

**Intelligent Planner**

- Models, Generates, Validates and Translates Plans
- Maintains Models of Plans, Agents, And Objects
- Uses Techniques of Temporal Logic, Nonlinear Planning, and Hierarchical Abstraction

**Agents**

- Puma 560 Possessing Vision, Force/Torque, and Tactile Sensors
- Graphical Robotic Simulator Modeling One and Two Armed Robots
- Human Interaction via Voice Recognition and Synthesis Systems
Section: Status

Title: Benefits of Approach

1. Generation

The temporal logic representation allows the planner to generate plans which incorporate all possible orderings of execution by an agent. This is significant in providing plans which can be applied to agents possessing differing capabilities in sequential/parallel execution. The techniques of hierarchical abstraction allow operations procedures to be built up to a level which is natural for operations engineers. Hence, these procedures can be modeled by non-robotic developers, but still be translated for a specific robotic agent. Such a benefit will make robotic automation accessible to a broader group of developers.

2. Validation

The ability to determine whether an agent is capable of plan execution is central to the robust theme of compatibility. New robotic designs can be modeled and verified against operation procedures already in existence. Similarly, modifications to operations procedures can be validated to ensure compatibility with any existing robotic hardware. By validating procedures for both crewmembers and robots, areas of future robotic development can be targeted to bridge any gaps in human and robotic capabilities.

3. Translation

A plan be generated only once for it to be translated as often as needed for whatever agents are needed. Translation separates the development of operations procedures from the specific execution details, thus establishing consistency in procedure development. By incorporating developed plans into the plan library, they can be re-used for future robotic applications. Since development of procedures is independent from development of robotics, a change in the robotic execution can still use a previously generated plan.
Benefits of Approach

**Generation:** *autonomously creates plans from existing task library*
- temporal logic allows reasoning about all possible methods for execution
- non-robotic developers can model activities

**Validation:** *determines whether an agent is capable of plan execution*
- new robotic designs can be verified against existing procedures, and vice versa
- areas for future robotic development can be discovered and analyzed

**Translation:** *convert same plan into instructions for different agents*
- procedure consistency
- re-usable software for robotic applications

Abstraction Prevents Plan Obsolescence From Future Sophistications In Robotics
Section: Status
Title: Directions for Future Research

1. Planning Investigations

Adding nonmonotonic properties to the temporal logic will vastly improve the computational complexity of current temporal logic algorithms. It will provide the ability to efficiently re-tract assertions made in the planning models. Such a capability will be significant in generating plans from abstract, or time-variable data. This nonmonotonicity will also be incorporated into replanning strategies to reformulate the temporal networks of the plan models. Explanation facilities will be incorporated into the planner to extract rationale from temporal and functional constraints and explain the planner's decision to crewmembers.

2. Robotic Agent Investigations

Models for representing agents will be refined for better inheritance of agent characteristics. Methodologies for inheriting agent-specific instructions will be examined. These representations are targeted toward a stronger model of an agent's sensing capabilities. As a testbed for these models, we will incorporate a three-fingered end-effector for dexterous manipulation of objects. Issues in active and passive compliance with the environment will be studied, with the eventual goal of active compliance with a crewmember, and the receipt of cooperative plans.

3. Human Interface Investigations

Models for crew skills will be developed to allow the planner to generate English sentences with varying amounts of detail. Different classes of crew skills will be incorporated into the agent knowledge base to help guide the explanation of planner rationale to

PATHS FOR FTS EVOLUTION

FULL TELEPRESENCE

STATE-OF-THE-ART

TRUE ROBOT
IDENTIFICATION OF HIGH PAYOFF TECHNOLOGY

- FTS mission utilization team scripted representative tasks
- Task scripts analyzed for commonality
- Generic task definitions developed
- Scripted tasks mapped into generic task definitions
FREQUENTLY PERFORMED ACTIONS

- Orient torso
- Move arms to vicinity of work
- Attach
- Detach
PRIMARY TASK STATES

- Path Planning
- Non-contact alignment
- Contact Planning and Control
TASK STATES

- movement through large volumes
- primarily translation
- free space motion

- movement through small volumes
- primarily orientation
- free space motion

- movement through small volumes
- contact with environment
- compliance strategies required
EPS RADIATOR PANEL INSTALLATION

1. Unstow FTS from shelter
2. Unstow PDGFs from shelter and store in payload bay
3. Move to IEA bay
4. Install PDGFs
5. Detach diagonal truss member
6. Position FTS for radiator panel installation
7. Unstow magazine from payload bay
8. Position magazine for radiator panel installation
9. Attach radiator panel guide
10. Install panels
11. Stow magazine in payload bay
12. Detach FTS from PDGF
13. Attach diagonal truss
14. Detach PDGFs from nodes and store in bay
15. Position orbiter to shelter
16. Stow PDGFs
17. Stow FTS
GENERIC TASK DEFINITIONS

RETRIEVE ROBOT
Transport work system (e.g. RMS, OMV, MSC) active FTS action is positive release of the grapple fixture

TEST ROBOT
FTS is active system

DELIVER ROBOT WORK SYSTEM
Transport work system (e.g. RMS, OMV, MSC) active FTS action is a positive "grab" of grapple fixture

ORIENT TORSO
FTS positioning system is active system
Requires: Observe, designate, and plan path, utilization of FTS positioning system to approach zone of manipulation

MOVE ARMS TO VICINITY OF WORK
FTS manipulator arms are active systems
Requires: Observe, designate, and plan path, move end effectors to vicinity of work
ATTACH
FTS end effector and arms are active systems
Requires: Iterate until seating verified: Observe/sense, designate, and plan path, align (may use vision force feedback, guides, etc.), move

DO WORK
FTS is active system
Requires: Observe, designate activities for completion of task and plan path required to complete task
Will include one or more of the following: move, insert, drive, push, pull, twist, turn, engage, disengage, count turns, follow, deploy, lock, align

DETACH
FTS manipulator arms and end effectors are active systems
Requires: Observe, designate, and plan retract path, align/null store energy, disengage end effector, retract

MOVE ARMS TO SAFE POSITION
FTS manipulator arms are active systems
Requires: Observe, designate, and plan path, move

</table>
APPROACH TO DEFINING EVOLUTION ALTERNATIVES

- Use "decision tree" process flow diagrams
- Identify technological dichotomies
  - environmental structuring
  - sensor processing capabilities
  - control algorithms
  - human interaction
- Choose a path through tree
NON-CONTACT ALIGNMENT

(assumes motion will be within a small volume and primarily in orientation)

(primary source of data is a camera image and a low level vision system exists)

(initial condition is that target is in field of view and sufficiently large for processing)
CONTACT PLANNING AND CONTROL
(assumes that a non-contact alignment has been performed)

GOAL STATE
(e.g., nut runner mated to nut)

PASSIVE COMPLIANCE
(e.g., active compliance)

GATHER SENSOR DATA

AUTOMATICALLY CALCULATE ERROR TO GOAL
(i.e., forces in all axes meet predefined spec)

REACHED GOAL STATE

DONE (SUCCESS)

DONE (ERROR)

MOVE IN DESIRED DIRECTION

OTHER SENSORS AVAILABLE

SENSOR WITHIN LIMITS

DONE (SUCCESS)
NON-CONTACT ALIGNMENT

(assumes motion will be within a small volume and primarily in orientation)

(primary source of data is a camera image and a low level vision system exists)

(initial condition is that target is in field of view and sufficiently large for processing)
CONTACT PLANNING AND CONTROL

(assumes that a non-contact alignment has been performed)

- Passive Compliance
  - Yes (e.g. remote center compliance device)
  - No (e.g. active compliance)

- Goal State
  - Yes (e.g. nut runner mated to nut)
  - No

- Gather Sensor Data
  - Yes
  - No

- Automatically Calculate Error To Goal
  - Yes (forces in all axes meet predefined spec)
  - No

- Reached Goal State
  - Yes
  - No

- Done (SUCCESS)
- Done (ERROR)

- Teleop

- Move In Desired Direction
  - Yes
  - No

- Other Sensors Available
  - Yes
  - No

- Sensor Within Limits
  - Yes
  - No

- Done (SUCCESS)
HUMAN OPERATOR INTERFACE

Operator Command Level

TASK STEPS

1. Orient Torso
2. Arms to Vicinity of Task
3. Attach Bolt Runner
4. Drive Bolt Out
5. Orient Torso
6. Attach
7. Align PDGF
CONCLUSIONS

- Described methodology for determining high payoff automation tasks
- Described tradeoffs between autonomy and human assistance for:
  - non contact alignment
  - path planning
  - contact alignment and control
