TECHNICAL NOTE 3389

AXIALLY SYMMETRIC SHAPES WITH MINIMUM WAVE DRAG

By Max. A. Heaslet and Franklyn B. Fuller

Ames Aeronautical Laboratory
Moffett Field, Calif.

Washington
February 1955
SUMMARY

The external wave drag of bodies of revolution moving at supersonic speeds can be expressed either in terms of the geometry of the body, or in terms of the body-simulating axial source distribution. For purposes of deriving optimum bodies under various given conditions, it is found that the second of the methods mentioned is the more tractable. By use of a quasi-cylindrical theory, that is, the boundary conditions are applied on the surface of a cylinder rather than on the body itself, the variational problems of the optimum bodies having prescribed volume or caliber are solved. The streamwise variations of cross-sectional area and drags of the bodies are exhibited, and some numerical results are given. The solutions are found to depend upon a single parameter involving Mach number and the radius-length ratio of the given cylinder. Variation of this parameter from zero to infinity gives the spectrum of optimum bodies with the given condition from the slender-body result to the two-dimensional. The numerical results show that for increasing values of the parameter, the optimum shapes quickly approach the two-dimensional.

A reciprocity relation for axial flow is derived, and it is used in formulating the variational problems in terms of the drag formula involving geometry. Formulation of the minimum problems in terms of combined flow fields is found to lead to extremely simple relations that are satisfied by the flow fields induced by optimum bodies. The combined flow concepts are also useful, for example, in checking results found by other means.

INTRODUCTION

The design of minimum-drag configurations is one of the fundamental problems of aerodynamics. For many engineering purposes it is, furthermore, possible to make useful predictions and design calculations for steady flight by considering additively the drag attributable to the viscous nature of the air and the drag that occurs in an inviscid medium. Since efficient flight is closely associated with the use of aerodynamic shapes producing relatively small disturbances in the air, the analysis upon which the inviscid-fluid theory is based can, in many cases of practical interest, be further limited to first-order approximations involving small perturbations. For supersonic flight speeds such an analysis is
linear, the perturbation velocity potential of the flow field satisfies
the wave equation, and the pressure drag of nonlifting configurations
results from the accumulation of energy in the waves induced by the body
during its motion.

The purpose of the present paper is to show how most favorable body
shapes, under various given conditions, can be derived by using formulae
for drag prediction that are based upon the linearized theory. The type
of body to be treated is a nacelle- or duct-like configuration (nonlifting
and having axial symmetry) which induces perturbations that are specified
on the surface of a circular cylinder. The analysis might be termed quasi-
cylindrical, since boundary conditions are applied on the surface of a
cylinder rather than on the body itself. Only the external flow is con-
sidered.

There are two rather different methods available for the calculation
of drag of such bodies. The first, given by Ward in reference 1, expresses
the drag in terms of the geometry of the body and of a weighting function
first encountered by Lighthill (ref. 2) in connection with the drag of
fusiform bodies. The second result, published recently by Parker
(ref. 3), is a formula in which the drag is expressed in terms of the
strength of an axial source distribution that simulates the body shape.
Generally speaking, the formula giving drag directly in terms of geomet-
rical characteristics would be preferable, since the usual auxiliary con-
ditions in variation problems, such as given volume, given caliber, etc.,
are also expressed in geometrical terms. Unfortunately, however, the
variational problem in this case leads to an integral equation whose
kernel is the Lighthill function mentioned previously, and the properties
of this function are not at present well enough known to enable one to
solve the integral equation by other than numerical methods. On the
other hand, the expression for drag in terms of sources leads to a trac-
table integral equation, although the relations between source strength
and geometry are somewhat complex.

Problems of the sort to be treated here have been attacked by Ferrari
(refs. 4 and 5) and by Parker (ref. 3). The first-named author has
approached the problem of minimum drag with assorted isoperimetric con-
ditions by both the above-mentioned methods, but the main effort was made
in connection with the source-strength method applied in conjunction with
a control surface consisting of a frustum of a cone. A large number of
cases have been worked out, mostly by numerical methods. The other work,
reference 3, gives a solution to the problem of the minimum-drag body
with given caliber, making use of boundary conditions on the Stokes'
stream function, rather than the potential function.

In this paper we shall approach the problem by the use of both methods
outlined above. In an introductory section, the operational approach to
the wave equation is extended to bodies having peripheral as well as
longitudinal variations of surface shape. The analysis is then restricted
to the case of axial symmetry and the two drag formulae are given. Then
a reciprocity relation for axial flow is derived, and the notion of
combined flow fields is introduced. This device leads, through application of the reciprocity relation and the drag formula in terms of body geometry, to extremely simple physical characterizations of the flow fields associated with optimum bodies. Next, in order to derive explicit expressions for some optimum bodies we consider the source-function approach in combination with a cylindrical control surface on which boundary conditions are specified. The results obtained are discussed with the aid of numerical examples, and, finally, the reciprocity relations derived earlier are exhibited in terms of the explicit solutions found, and some uses of the reciprocity results are indicated.

The Appendix is devoted to summarizing the results of the minimizations for the convenience of the reader.

**LIST OF IMPORTANT SYMBOLS**

- \( a_0 \) speed of sound in free stream
- \( A_0(x) \) strength of source distribution
- \( B(\sigma) \) function used in isoperimetric problems (See eqs. (60).)
- \( C_p \) pressure coefficient, \( \frac{P-P_0}{\frac{1}{2} \rho_0 U_0^2} \)
- \( D \) drag
- \( E \) complete elliptic integral of second kind of modulus \( k \)
- \( k \) modulus of elliptic integrals
- \( K \) complete elliptic integral of first kind of modulus \( k \)
- \( K_{m,lm} \) Bessel functions of order \( m \) (See ref. 8.)
- \( l \) length of body
- \( M_0 \) Mach number in the free stream, \( \frac{U_0}{a_0} \)
- \( n_1, n_2, n_3 \) direction cosines with respect to Cartesian axes of the inward normal to a surface
- \( P \) pressure
- \( P_0 \) pressure in the free stream
- \( P \) pressure in a combined flow field, \( P - \bar{P} \)
- \( q_0 \) dynamic pressure, \( \frac{1}{2} \rho_0 U_0^2 \)
r \quad \text{radial coordinate}, \sqrt{y^2 + z^2}

\Delta r(x) \quad \text{incremental radius on control cylinder due to source distribution along axis}

R \quad \text{radius of cylindrical control surface}

S(x) \quad \text{cross-sectional area of a body}

\Delta S(x) \quad S(x) - S(0)

x,y,z \quad \text{Cartesian coordinates}

u,v,w \quad \text{perturbation velocities in } x,y,z \text{ directions, respectively}

U_0 \quad \text{free-stream velocity}

v_r \quad \text{perturbation velocity in radial direction}

V \quad \text{volume of body}

V_e \quad \text{additional volume wrapped on cylindrical control surface}

W(z) \quad \text{function defined in equation (25)}

\alpha^2 \quad \text{parameter of elliptic integral of third kind}

\beta^2 \quad M_0^2 - 1

\eta \quad \text{dimensionless streamwise coordinate}, \frac{x}{l}

\theta \quad \text{angular coordinate}, \tan^{-1} \frac{z}{y}

\lambda, \mu \quad \text{Lagrange multipliers in isoperimetric problems}

\Pi(\alpha^2,k) \quad \text{complete elliptic integral of third kind of modulus } k \text{ and parameter } \alpha^2 \text{ (in notation of ref. 20)}

\rho_0 \quad \text{free-stream density}

\sigma \quad \frac{\beta R}{l}

\phi \quad \text{perturbation velocity potential}

\text{Suffixes}

' \quad \text{differentiation with respect to streamwise coordinate}

\sim \quad \text{quantity evaluated in reversed flow field}
Laplace transform

* dimensionless quantity as $V^* = \frac{V}{l^2}$, $S^* = \frac{S}{l^2}$, etc.

INTRODUCTORY ANALYSIS

The analysis to be given here is adapted to boundary conditions specified on a right circular cylinder so oriented that its axis is parallel to the free-stream velocity vector. Immediate application thus follows for quasi-cylindrical shapes that deviate slightly, both longitudinally and peripherally, from a cylindrical control surface although the expression for drag can be extended to include the domain of slender-body theory.

Consider a Cartesian coordinate system fixed relative to a supersonic free-stream velocity $U_0$ and Mach number $M_0 = U_0/a_0 > 1$ where $a_0$ is the velocity of sound in the free stream. The x axis is aligned with the direction of the flow and the lateral coordinates $y,z$ may also be expressed in polar coordinates $r, \theta$ where $r = \sqrt{y^2 + z^2}$, $\theta = \tan^{-1}z/y$. A cylindrical control surface of radius $r = R = \text{const.}$ is given with the range $0 \leq x \leq l$ and on this control surface the perturbation velocity components, together with their gradients, are small relative to $U_0$ and $U_0/l$. Under these conditions the field external to the cylinder of radius $R$ has for its governing equation the linear relation

$$\beta^2 \varphi_{xx} - \varphi_{yy} - \varphi_{zz} = 0$$

(1)

where the subscript notation denotes partial differentiation, $\varphi(x,y,z)$ is the perturbation velocity potential yielding the perturbation velocity components

$$u(x,y,z) = \varphi_x(x,y,z), \quad v(x,y,z) = \varphi_y(x,y,z), \quad w(x,y,z) = \varphi_z(x,y,z)$$

and $\beta^2 = M_0^2 - 1$. The boundary conditions on the body are to be taken in the form

$$\varphi_r(x,r,\theta) \big|_{r=R} = U_0 G(x,\theta), \quad 0 \leq x \leq l$$

(2)

where $G$ is a known function of $x$ and $\theta$. 
A General Solution of the Wave Equation in Cylindrical Coordinates

If equation (1) is rewritten in the form

$$\beta^2 \varphi_{xx} - \varphi_{rr} - (1/r) \varphi_r - (1/r^2) \varphi_{\theta \theta} = 0$$  \hspace{1cm} (3)

it is possible, through separation of variables, to derive a general solution representing a rectilinear distribution of source and multipole singularities. This general solution can be found by use of the Laplace transformation. By definition, the Laplace transform (see ref. 6) of a function $F(x,r,\theta)$ is $\mathcal{F}(s;r,\theta)$ where

$$\mathcal{F}(s;r,\theta) = \int_0^\infty e^{-sx} F(x,r,\theta) dx$$  \hspace{1cm} (4)

If one employs this transformation and applies initial conditions consistent with supersonic flow theory (ref. 7), equation (3) becomes

$$\beta^2 s^2 \varphi - \varphi_{rr} - (1/r) \varphi_r - (1/r^2) \varphi_{\theta \theta} = 0$$  \hspace{1cm} (5)

The transform of the perturbation velocity potential is assumed separable in the form

$$\bar{\varphi}(s;r,\theta) = \zeta(r,s) \cos m\theta$$

and it follows directly that $\zeta(r,s)$ must satisfy the ordinary differential equation

$$\frac{d^2 \zeta}{d(\beta rs)^2} + \frac{1}{\beta rs} \frac{d \zeta}{d(\beta rs)} - \left[ 1 + \frac{m^2}{(\beta rs)^2} \right] \zeta = 0$$

Thus, the solution can be written

$$\bar{\varphi}(s;r,\theta) = -\frac{1}{2\pi} \sum_0^\infty \cos m\theta \left[ \mathcal{A}_m(s) K_m(\beta rs) + \mathcal{B}_m(s) I_m(\beta rs) \right]$$

---

1It will be assumed through the present section that the origin lies upstream of all disturbance points in the flow field. Subsequently, the origin will be shifted so as to lie at the upstream face of the control surface or body.
where $K_m$ and $I_m$ are modified Bessel functions in the notation of reference 8. The asymptotic expansions for the Bessel functions show that $I_m$ yields incoming waves suitable for the analysis of flow inside a tube or cylindrical control surface; $K_m$ yields outgoing waves that are suited to the calculation of the field external to a tube. It follows that one has, in the latter case,

$$\overline{\varphi}(s;r,\theta) = -\frac{1}{2\pi} \sum_{0}^{\infty} A_m(s)K_m(\beta rs)\cos m\theta$$  \hspace{1cm} (6)

The inversion of equation (6) can be achieved in two ways. First, from reference 9, page 277, and the convolution integral, one gets

$$\varphi(x,r,\theta) = -\frac{1}{2\pi} \left[ \int_{0}^{x}\frac{A_0(x_1)dx_1}{\sqrt{(x - x_1)^2 - \beta^2 r^2}} + \sum_{1}^{\infty} \cos m\theta \int_{0}^{x}\frac{A_m(x_1)\cosh(m\cosh^{-1}\frac{x - x_1}{\beta r})dx_1}{\sqrt{(x - x_1)^2 - \beta^2 r^2}} \right]$$ \hspace{1cm} (7)

Second (see, e.g., ref. 8, p. 79), one has

$$K_m(\beta rs) = (-1)^m \frac{r^m}{\beta^m m!} \left(\frac{d}{dr}\right)^m K_0(\beta rs)$$

Thus equation (6) can be rewritten as

$$\overline{\varphi}(s;r,\theta) = -\frac{1}{2\pi} \left[ A_0(s)K_0(\beta rs) + \sum_{1}^{\infty} \left(\frac{r}{\beta}\right)^m \cos m\theta \left(\frac{d}{dr}\right)^m \frac{A_m(s)}{s^m} K_0(\beta rs) \right]$$

and the inversion is

$$\varphi(x,r,\theta) = -\frac{1}{2\pi} \left[ \int_{0}^{x}\frac{A_0(x_1)dx_1}{\sqrt{(x - x_1)^2 - \beta^2 r^2}} + \sum_{1}^{\infty} \left(\frac{r}{\beta}\right)^m \cos m\theta \left(\frac{d}{dr}\right)^m \int_{0}^{x}\frac{C_m(x_1)dx_1}{\sqrt{(x - x_1)^2 - \beta^2 r^2}} \right]$$ \hspace{1cm} (8)
where the function \( C_m(x) \) is given by (from operational calculus rules)

\[
C_m(x) = \int_0^x dx_m \cdots \int_0^{x_2} dx_2 \int_0^{x_1} A_m(x_1) dx_1
\]

\[
= \frac{1}{(m - 1)!} \int_0^x (x - x_1)^{m-1} A_m(x_1) dx_1
\]

Equation (8) expresses the solution in the usual form, given, for example, in reference 10, page 527. For some purposes, numerical calculations for example, equation (7) has advantages over equation (8). The two solutions express the perturbation velocity potential in terms of distributions of singularities along the central axis, the first term representing a distribution of supersonic sources of strength \( A_0(x)dx \), and the subsequent terms representing multipoles of order \( m \).

It is of interest to calculate the limiting forms of equations (7) and (8) for large and small values of \( r \). For large \( r \), equation (6) becomes

\[
\varphi(s;r,\theta) \approx \frac{1}{2\pi} \sum_{m=0}^{\infty} \frac{A_m(s)}{A_0(s)} \sqrt{\frac{\pi}{2\beta rs}} e^{-\beta rs \cos m\theta}
\]

where the asymptotic form

\[
K_m(z) \approx \sqrt{\frac{\pi}{2z}} e^{-z}
\]

has been used. The perturbation velocity potential is then

\[
\varphi(x,r,\theta) \approx -\frac{1}{2\pi \sqrt{2\beta r}} \sum_{m=0}^{\infty} \cos m\theta \int_0^{x-\beta r} A_m(\xi) \frac{d\xi}{\sqrt{x - \xi - \beta r}}
\]

The ultimate attenuation of \( \varphi \) with lateral distance is therefore fixed by the factor \( 1/\sqrt{r} \). For small \( r \), equation (6) becomes

\[
\varphi(s;r,\theta) \approx -\frac{1}{2\pi} \left[ -A_0(s) \left( \ln \frac{\beta rs}{2} + \gamma \right) + \sum_{m=1}^{\infty} \frac{A_m(s)}{2} (m - 1)! \left( \frac{2}{\beta rs} \right)^m \cos m\theta \right]
\]
where \( \gamma = 0.577 \) is Euler's constant. The inversion of equation (12) is

\[
\varphi(x,r,\theta) \approx \frac{1}{2\pi} \left[ A_0(x) \ln \frac{\beta r}{2} + \frac{\partial}{\partial x} \int_0^x A_0(x_1) \ln |x - x_1| \, dx_1 + \right. \\
\left. \sum_{m=1}^{\infty} \frac{(2m+1)}{2m} \frac{(m-1)!}{(m-1)!} \cos m\theta \, C_m(x) \right]
\]

(13)

where \( C_m(x) \) is defined in equation (9). This result was used by Ward (ref. 11) as a basis for the development of slender-body theory.

As presented, the above general solutions (eqs. (7) and (8)) were not related to specific boundary conditions. The formal development of this relation is straightforward and leads to an explicit solution for boundary conditions given on the cylindrical-control surface at \( r = R = \text{const.} \)

Let the given conditions be

\[
\varphi_r \big|_{r=R} = U_0 G(x,\theta) = U_0 \sum_{m=0}^{\infty} \tilde{a}_m(x) \cos m\theta
\]

(14)

From equations (6) and (14), one has

\[
\varphi_r (s; r, \theta) \big|_{r=R} = -\frac{1}{2\pi} \sum_{m=0}^{\infty} \tilde{A}_m(s) \left[ \frac{d}{dr} K_m(\beta rs) \right] \cos m\theta = U_0 \sum_{m=0}^{\infty} \tilde{a}_m(s) \cos m\theta
\]

(15)

Since

\[
\frac{d}{dr} K_m(\beta rs) = \beta s K_m'(\beta rs)
\]

equation (15) yields

\[
\tilde{A}_m(s) = -\frac{2\pi U_0}{\beta} \frac{\tilde{a}_m(s)}{s K_m'(\beta rs)}
\]

(16)

and the transformed velocity potential is, from equation (6),

\[
\varphi(s; r, \theta) = -\frac{U_0}{\beta} \sum_{m=0}^{\infty} \frac{\tilde{a}_m(s)}{s} \frac{K_m(\beta rs)}{K_m'(\beta rs)} \cos m\theta
\]

(17)
In order to give the desired expression for \( \phi(x,r,\theta) \) it is necessary to calculate the inverse Laplace transform of the functions \( K_m(\beta rs)/K_m'(\beta rs) \). This task has been undertaken by Mersman (ref. 12).

**External Wave Drag of Quasi-Cylindrical Body of Revolution**

**In Terms of Its Geometry or Source Distribution**

Attention is now restricted to flow fields possessing axial symmetry with respect to the stream direction. Independence with respect to \( \theta \) then reduces equations (7) and (8) to

\[
\phi(x,r) = -\frac{1}{2\pi} \int_{0}^{x} \frac{A_0(x_1)dx_1}{\sqrt{(x - x_1)^2 - \beta^2 r^2}}
\]

and the velocity potential is expressed as a rectilinear distribution of supersonic source potentials. Operationally, equation (18) takes the form

\[
\overline{\phi}(s;r) = -\frac{1}{2\pi} \overline{A_0}(s)K_0(\beta rs)
\]

The axes may now be considered as shifted so that the source distribution starts at \( x = -\beta R \) and induces perturbation velocities on the cylindrical surface \( r = R, 0 \leq x \leq l \). For \( r \geq R \) one then has the disturbance field associated with a body of revolution that deviates only slightly from the cylinder \( r = R \). The wave drag of such a body can then be expressed in two ways: first, as a function of the body geometry; second, as a function of the source-strength distribution. The first result has been given in reference 1. To the order of accuracy to which this control-surface theory applies, the slope of the resulting surface is

\[
\frac{dr}{dx} \approx \frac{S'(x)}{2\pi R} \approx \frac{1}{U_0} \left[ \phi_r \right]_{r=R}
\]

where \( S'(x) \) is the streamwise derivative of local cross-sectional area of the body. This condition, together with equation (19), yields

\[
\frac{\overline{A_0}(s)}{U_0} = \frac{\overline{S'(s)}}{\beta RsK_1(\beta Rs)}
\]
where $S'(s)$ means the Laplace transform of $S'(x)$, and

$$\frac{\overline{f(s;R)}}{U_0} = - \frac{S'(s)}{U_0} \frac{K_0(\beta RS)}{2\pi \beta RS K_1(\beta RS)} \tag{22}$$

In order to calculate drag, pressure on the body is next evaluated. Denoting by $p$ and $p_o$ local and free-stream pressure and setting $q_0 = \frac{1}{2} \rho_o U_0^2$, one has in linearized theory

$$\frac{p - p_o}{q_o} \bigg|_{r=R} = - \frac{2u(x;R)}{U_0} \tag{23}$$

From equation (22)

$$\overline{u(s;R)} = - \frac{1}{2\pi \beta R} \overline{S'(s)} \frac{K_0(\beta RS)}{K_1(\beta RS)} = - \frac{S'(s)}{2\pi \beta R} \left[ 1 - \frac{K_1(\beta RS) - K_0(\beta RS)}{K_1(\beta RS)} \right] \tag{24}$$

The inverse transform of the second term involving the Bessel function leads to the function $W(x)$ introduced by Lighthill (ref. 2). By definition, its transform is

$$\overline{W(s)} = \frac{K_1(s) - K_0(s)}{K_1(s)} \tag{25}$$

Pressure distribution on the body can then be calculated from the expression

$$\frac{p - p_o}{q_o} = \frac{1}{\pi \beta R} \left[ S'(x) - \int_{x_1}^x S'(x) W\left(\frac{x - x_1}{\beta R}\right) \frac{dx_1}{\beta R} \right] \tag{26}$$

The function $W(x)$ is shown in sketch (a); tabular values for $-2 < x < 10$ are given in reference 1.

The external wave drag $C_{D_w}$ of the body is finally determined by direct integration

![Graph of $W(x)$](Sketch (a))
Equation (18) expresses the potential of a source distribution of strength \( A_0(x) \, dx \). On the cylindrical control surface \( r = R \) and within the range \( 0 \leq x \leq L \) an effective body shape is induced and the drag of this body can be calculated as follows. The streamwise and lateral perturbation-velocity components are, respectively,

\[
\phi_x(x,r) = -\frac{1}{2\pi} \int_{-\beta R}^{x-\delta R} \frac{A_0'(x_1) \, dx_1}{\sqrt{(x-x_1)^2 - \beta^2 r^2}} \tag{29}
\]

and

\[
\phi_r(x,r) = \frac{1}{2\pi} \int_{-\beta R}^{x-\delta R} \frac{(x-x_1)A_0'(x_1) \, dx_1}{\sqrt{(x-x_1)^2 - \beta^2 r^2}} \tag{30}
\]

where \( A_0(x_1) = 0 \), for \( x_1 \leq -\beta R \). The effective body, within the range \( 0 \leq x \leq L \), is fixed by the boundary conditions of equation (20) and its external wave drag is

\[
C_D = \frac{\text{drag}}{\pi R^2 q_0} = \frac{1}{\pi R^2} \int_0^L \frac{p - p_0}{q_0} s'(x) \, dx \tag{27}
\]

and from equation (26) is

\[
C_D = \frac{1}{2\beta R^2 R} \left\{ 2 \int_0^L [s'(x)]^2 \, dx - \frac{1}{\beta R} \int_0^L \int_0^L s'(x)s'(x_1)W\left(\frac{|x - x_1|}{\beta R}\right) \, dx \, dx_1 \right\} \tag{28}
\]

In a later section entitled "Geometric Criteria for Minimum Drag," the role equation (28) plays in problems involving drag minimization will be discussed. For the present, it may be remarked that although the magnitude of the influence function \( W(x) \) is known, its analytic properties are not well enough defined to permit easy manipulation. It will become more apparent later that for certain minimum-drag problems an advantage is provided when one deals directly with source distributions and establishes the relationship between geometry and source strengths as a separate part of the analysis.
\[ D = -2\pi \rho_o R \int_0^2 \phi_x(x_1R)\phi_r(x_1R)dx \]

\[ = \frac{\rho_o}{2\pi} \int_0^2 dx \int_{-\beta R}^{x-\beta R} A_0'(x_1)(x - x_1)dx_1 \int_{-\beta R}^{x-\beta R} \frac{A_0'(x_2)dx_2}{\sqrt{(x - x_1)^2 - \beta^2R^2}} \]

(31)

The dummy variables \( x_1, x_2 \) can be interchanged; if one then combines the two expressions of equation (31) and inverts the order of integration, the integration with respect to \( x \) can be performed and there results

\[ D = \frac{\rho_o}{4\pi} \int_{-\beta R}^{l-\beta R} A_0'(x_1)dx_1 \int_{-\beta R}^{l-\beta R} A_0'(x_2)\cosh^{-1}\left[ \frac{(l - x_1)(l - x_2) - \beta^2R^2}{\beta R(x_1 - x_2)} \right] dx_2 \]

(32)

as given in reference (3).

It is of interest to remark that although equation (32) uses only a knowledge of the function \( A_0(x) \) in the range \(-\beta R \leq x \leq l - \beta R\), the drag that is calculated presupposes a specific source distribution function in the range \( l - \beta R < x \) if one wishes to identify the drag with a geometric shape. Thus, as in sketch (b), if the body shape near \( r = R \) is assumed to have some arbitrary variation for \( 0 \leq x \leq l \), and to straighten out into a purely cylindrical surface downstream of \( x = l \), a source distribution function is required downstream of \( x = l - \beta R \) to produce the cylinder.
The fact that the stream velocity is supersonic means that upstream influences of $A_0(x)$ for $x > l - \beta R$ cannot be felt on the body and explains why the drag of a complete geometric shape can be determined from its source distribution without knowing the complete details of the distribution function.

As another example of the use of equation (32) consider, as in sketch (c), a circular body extending from $x = -\beta R$ to $x = l$ with a cylindrical afterbody of radius $R$ aft of $x = l$. If the source distribution of this body is known as, say, for example, in the case of a cone or slender body of revolution, the body drag can be determined by using the surface $r = R$, $0 \leq x \leq l$ as a control surface and calculating momentum transport through the control surface. Equation (32) is the exact expression for the body drag, and, again, requires no knowledge of source strength beyond $x = l - \beta R$.

**COMBINED FLOW FIELDS**

One method of attack that has proved to be extremely helpful in the analysis of problems in aerodynamic theory involves a symmetrization process in which flow fields in both forward and reverse flow are related. Attention, up to the present time, has been devoted principally to planar-type problems and in reference 13 Jones has used this approach to derive criteria that appear in the minimization of wave drag of, for example, nonlifting wings having specified thickness ratios or volumes. In this section, a brief discussion is given, using the methods of reference 14, of the way these concepts appear in cylindrical-control-surface analysis.

The Reciprocity Relation for Axial Flow

Equation (1) can be written

$$L(\varphi) \equiv \beta^2 \varphi_{xx} - \varphi_{yy} - \varphi_{zz} = 0 \quad (33)$$

where $L(\varphi)$ is a self-adjoint linear operator. Let now $\Psi(x,y,z)$ and $\Omega(x,y,z)$ be two solutions of equation (33) satisfying boundary conditions given on a circular cylinder. Reciprocal relations between $\Psi$ and $\Omega$ can
be derived by applying Green's theorem over a prescribed geometric region. Consider, as shown in sketch (d), the cylindrical control surface extending from \( x = 0 \) to \( x = l \) and draw the enveloping Mach cones at the front and rear of the surface. Denote the cylindrical surface by \( \Sigma_1 \), the front Mach cone \( x - \beta r = -\beta R \) by \( \Sigma_2 \), and the rear cone \( x + \beta r = l + \beta R \) by \( \Sigma_3 \). These surfaces enclose a toroidal region, bounded internally by \( \Sigma_1 \) and externally by \( \Sigma_2 \) and \( \Sigma_3 \). It follows from Green's theorem that the integral relation

\[
\int \int \psi (-\beta^2 n_1 \frac{\partial \psi}{\partial x} + n_2 \frac{\partial \psi}{\partial y} + n_3 \frac{\partial \psi}{\partial z}) \, d\Sigma
\]

applies where the surface integration extends over \( \Sigma_1, \Sigma_2, \Sigma_3 \) and \( n_1, n_2, n_3 \) are direction cosines, with respect to the \( x, y, z \) axes, of the surface normal directed inward into the region.

It is customary to re-express relations like equation (34) in terms of a newly defined directional derivative along a line termed the conormal. In this manner, the equation becomes

\[
\int \int \psi \Lambda \frac{\partial \psi}{\partial \nu} \, d\Sigma = \int \int \Omega \frac{\partial \psi}{\partial \nu} \, d\Sigma \quad (35)
\]

where

\[
\frac{\partial \psi}{\partial \nu} = \frac{\partial \psi}{\partial x} \nu_1 + \frac{\partial \psi}{\partial y} \nu_2 + \frac{\partial \psi}{\partial z} \nu_3 \quad (36)
\]
and the direction cosines \( v_1, v_2, v_3 \) of the conormal are derived from
\[
-n_1\beta^2 = \Lambda v_1, \quad n_2 = \Lambda v_2, \quad n_3 = \Lambda v_3
\]

By calculation of the respective normals \( n_1, n_2, n_3 \) and using the relation \( v_1^2 + v_2^2 + v_3^2 = 1 \), it is readily found from the equations defining the conormal that on the surface \( \Sigma_1 \), the conormal is normal to the surface and \( \Lambda = 1 \); on a Mach cone, the conormal lies along the cone and \( \Lambda = \beta \).

Let now \( \psi \) be set equal to \( \varphi(x,r,\theta) \), the perturbation velocity potential associated with boundary conditions in a forward-flowing stream, and let \( \Omega \) be \( \tilde{u}(x,r,\theta) \), the x-wise component of perturbation velocity associated with boundary conditions in a stream flowing in the reverse direction. Under these conditions, equation (35) becomes

\[
\int_0^{2\pi} \int_0^l R \, d\theta \, \int_0^\varphi \tilde{u} \frac{\partial \varphi}{\partial r} \, dx + \beta \int_0^{2\pi} \int_0^l \varphi \frac{\partial \tilde{u}}{\partial r} \, dx + \beta \int_0^{2\pi} \int_0^l \varphi \frac{\partial \tilde{u}}{\partial v} \, d\Sigma_3
\]

On the Mach cone \( \Sigma_2 \), the perturbation potential may arbitrarily be set equal to zero and its conormal derivative along the cone will also be zero; as a consequence, the second terms on both sides of the equation vanish. Since the flow fields are irrotational, \( \partial \tilde{u}/\partial r = \partial \tilde{v}_r/\partial x \) where \( \tilde{v}_r \) is radial velocity. After making this substitution and integrating the first term in the right member by parts, one gets

\[
R \int_0^{2\pi} d\theta \int_0^l \tilde{v}_r dx = R \int_0^{2\pi} [\varphi(l,R,\theta)\tilde{v}_r(l,R,\theta) - \int_0^l \tilde{v}_r dx] d\theta
\]

\[
\beta \int_0^{2\pi} \int_0^{x_l} \left( \tilde{u} \frac{\partial \varphi}{\partial r} - \varphi \frac{\partial \tilde{u}}{\partial v} \right) dv
\]

The last integral becomes

\[
-\beta \int_0^{2\pi} \int_0^{x_l} (\sqrt{r} \, \tilde{u})^2 \, \frac{d}{dv} \left( \frac{\varphi}{\tilde{u}} \right) \, dv
\]
and for the given boundary conditions it is possible to show that along a conormal of $\Sigma_3$ the relation $\mathbf{v}_t = \beta \mathbf{u}$ holds and $\sqrt{r} \mathbf{u}$ is independent of $v$. The integral then can be rewritten as

$$\beta \int_0^{2\pi} \int_{x=\pi/2}^{x=\pi} (\sqrt{r} \mathbf{u})^2 \frac{d}{dv}(\frac{\mathbf{u}}{r}) dv = \beta R \int_0^{2\pi} \mathbf{u}(r,R,\theta) \mathbf{v}(r,R,\theta) d\theta$$

and one has, finally, the desired reciprocal theorem

$$-R \int_0^{2\pi} \int_0^l \mathbf{u}(r,R,\theta) \mathbf{v}_t(x,R,\theta) dx = R \int_0^{2\pi} \int_0^l \mathbf{u}(r,R,\theta) \mathbf{v}_t(x,R,\theta) dx$$

Equation (37)

It is not the purpose here to exploit the various applications of equation (37); rather, the role played by the reciprocal relation in drag calculations will be considered. In the forward and reverse flow fields, the pressure-velocity relations of linearized theory are

$$p - p_0 = -\rho_0 U_0 u, \quad \tilde{p} - p_0 = \rho_0 U_0 \tilde{u} \quad (38)$$

If, furthermore, thickness distributions of the form

$$r = f(x,\theta), \quad r = \tilde{f}(x,\theta)$$

are placed on the cylinder $r = R$, the boundary conditions are

$$\left[ \frac{1}{U_0} \frac{\partial \mathbf{u}}{\partial r} \right]_{r=R} = \frac{\partial f}{\partial x}, \quad \left[ \frac{1}{U_0} \frac{\partial \mathbf{u}}{\partial r} \right]_{r=R} = -\frac{\partial \tilde{f}}{\partial x}$$

Equation (38) can then be written

$$-\int_0^{2\pi} R d\theta \int_0^l (\tilde{p} - p_0) \frac{\partial f}{\partial x} dx = \int_0^{2\pi} R d\theta \int_0^l (p - p_0) \frac{\partial \tilde{f}}{\partial x} dx \quad (39)$$
An immediate consequence of this last result is that for a unique thickness distribution, that is, for \( f(x, \theta) = \bar{f}(x, \theta) \), the drag of a body in forward and reverse flow is the same. This follows from the fact that for quasi-cylindrical bodies the relations for drag are, respectively,

\[
D = R \int_0^{2\pi} \int_0^l (p - p_0) r=R \frac{\partial f}{\partial x} \, dx
\]

\[
\tilde{D} = - R \int_0^{2\pi} \int_0^l (\bar{p} - p_0) r=R \frac{\partial \bar{f}}{\partial x} \, dx
\]

For fixed geometry, therefore, drag is equal to half the sum of these two expressions

\[
D = R \int_0^{2\pi} \int_0^l (p - \bar{p}) r=R \frac{\partial f}{\partial x} \, dx
\]

Defining pressure \( P(x, r, \theta) \) in the combined flow fields by the following

\[
P(x, r, \theta) = p - \bar{p} = -\rho_0 U_0 (u + \bar{u})
\]  

one has

\[
D = R \int_0^{2\pi} \int_0^l P(x, R, \theta) \frac{\partial f}{\partial x} \, dx
\]  

If the body has axial symmetry, equation (41) reduces to the form given in equation (28). To show this, one notes first that \( P \) and \( f \) are independent of \( \theta \) and that equation (41) becomes

\[
D = \int_0^l P S'(x) dx
\]
The proof follows from the relations

\[ S'(x) = S'(x) \]

\[ \frac{u(x,R)}{U_0} = -\frac{1}{2\pi \beta R} \left[ S'(x) - \int_0^x S'(x_1) W \left( \frac{x - x_1}{\beta R} \right) \frac{dx_1}{\beta R} \right] \]

\[ \tilde{u}(x,R) = -\frac{1}{2\pi \beta R} \left[ S'(x) + \int_0^x S'(x_1) W \left( \frac{x_1 - x}{\beta R} \right) \frac{dx_1}{\beta R} \right] \]

\[ \frac{P(x,R)}{q_0} = \frac{1}{\pi \beta R} \left[ 2S'(x) - \int_0^x S'(x_1) W \left( \frac{|x - x_1|}{\beta R} \right) \frac{dx_1}{\beta R} \right] \]

Geometric Criteria for Minimum Drag

Consider now the problem of minimizing the wave drag of a quasi-cylindrical body subject to the condition that the volume of the body is constant. The body surface may be defined by

\[ r = f(x,\theta) = R + g(x,\theta) \]

The function \( g(x,\theta) \) determines the magnitude of the surface displacement from the cylinder \( r = R \); these displacements, as well as their gradients, are assumed small and we also assume

\[ g(x,\theta) \equiv 0 \] for \( x \leq 0 \) and \( l \leq x \)

If equation (41) is integrated by parts with respect to \( x \), the wave drag of the body becomes

\[ D = \frac{R}{2} \int_0^{2\pi} d\theta \int_0^l P'(x,R,\theta) g(x,\theta) dx \]

where the prime indicates \( x \)-wise differentiation of \( P \). The imposed
geometric constraint on the variational problem is

\[
\frac{1}{2} \int_0^{2\pi} d\theta \int_0^l r^2(x, \theta) dx = \frac{1}{2} \int_0^{2\pi} d\theta \int_0^l [R^2 + 2Rg(x, \theta)] dx
\]

\[
= \pi R^2 l + R \int_0^{2\pi} d\theta \int_0^l g(x, \theta) dx = V = \text{const.} \quad (45)
\]

where \( V \) is the total volume. The problem thus becomes one of minimizing the expression

\[
D - \mu V = - R \left\{ \frac{1}{2} \int_0^{2\pi} d\theta \int_0^l P'g(x, \theta) dx + \mu \left[ \pi Rl + \int_0^{2\pi} d\theta \int_0^l g(x, \theta) dx \right] \right\} \quad (46)
\]

where \( \mu \) is the Lagrangian multiplier. Carrying out the variation, one has

\[
\delta(D - \mu V) = - \frac{R}{2} \int_0^{2\pi} d\theta \int_0^l \left[ P'(\delta g) + g(\delta P') + 2\mu \delta g \right] dx = 0
\]

but from equation (37) or (39) it can be shown that the first two terms in the integrand yield equal integrals and the minimizing condition becomes

\[
\int_0^{2\pi} d\theta \int_0^l [P'(x, R, \theta) + \mu] \delta g dx = 0
\]

Since this latter equation must be satisfied by all possible variations of the displacement function \( g(x, \theta) \), it follows that the desired condition is

\[
P'(x, R, \theta) + \mu = 0 \quad (47)
\]

Stated in words, the condition for minimum wave drag of a quasi-cylindrical body of given volume is that the longitudinal gradient of pressure on the
body in the combined forward and reverse flow field is a constant. Furthermore, from equation (44), minimum drag is then given by

\[ D_{\text{min}} = \frac{1}{2} (V - \pi R^2 l) = \frac{1}{2} V_e \]  

(48)

where \( \mu \) can now be identified with the negative pressure gradient in the combined field and \( (V - \pi R^2 l) = V_e \) is the volume exposed to the fluid around the cylindrical control surface \( r = R \).

The actual cross-section-area variation of a minimum-drag constant-volume body and its pressure distribution are shown in sketch (e) for the case in which axial symmetry is imposed. Pressure coefficient in the combined flow field of an axially symmetric body has been given in equation (42). The geometric criterion just established then leads to the integral equation

\[ 2S'(x) - \int_0^l S'(x_1) W \left( \frac{|x - x_1|}{BR} \right) \frac{dx_1}{BR} = -\mu x + b \]  

(49)

and the solution of this equation will determine the body geometry. In the following section an analogous integral equation will be derived but with the source-strength distribution chosen as the fundamental dependent variable.

The combined-flow-field technique can also be used to study the problem of minimizing wave drag for specified body caliber or, more generally, when the body has a fixed cross section at a specified
longitudinal position. The resulting condition for minimum drag is that the pressure distribution on the body in the combined flow field is a constant forward and aft of the specified position. These conditions are all analogous to those obtained for planar problems by R. T. Jones (ref. 13).

**DRAG MINIMIZATION**

In this division, optimum bodies having certain prescribed geometric properties will be determined by standard variational methods. The analysis will, as mentioned previously, deal with the strength of an axial source distribution as the minimizing function, rather than the geometric quantity, cross-sectional area. Thus, we shall be concerned with formula (32), giving drag in terms of the source distribution.

**Quasi-Cylindrical Body of Revolution of Given Volume**

Isoperimetric conditions. - The configuration to be considered, together with associated nomenclature, is shown in sketch (f). The geometric properties of the body can be expressed in terms of the source distribution function $A_0(x)$ by using equation (20), namely,

$$S'(x) = \frac{2\pi R}{V_0} \varphi_R \bigg|_{r=R} \tag{50}$$

Then, from equation (30)

$$S'(x) = \frac{1}{U_0} \int_{-\beta R}^{x-\beta R} \frac{A_0'(x_1)(x - x_1)}{\sqrt{(x - x_1)^2 - \beta^2 R^2}} \, dx_1 \tag{51}$$

If equation (51) is integrated $x$-wise it is seen that

$$S(x) - S(0) = \frac{1}{U_0} \int_{0}^{x} \int_{-\beta R}^{2-\beta R(z - x_1)A_0'(x_1)} \frac{dz}{\sqrt{(z - x_1)^2 - \beta^2 R^2}} \tag{52a}$$
By changing the order of integration and performing the integration with respect to \( z \) one finds
\[
S(x) - S(o) = \frac{1}{U_0} \int_{-\beta R}^{x-\beta R} \left( x - x_1 \right) A_0(x_1) \frac{1}{\sqrt{(x - x_1)^2 - \beta^2R^2}} dx_1
\]  
(52b)

or, integrating by parts,
\[
S(x) - S(o) = \frac{1}{U_0} \int_{-\beta R}^{x-\beta R} A_0'(x_1) \frac{1}{\sqrt{(x - x_1)^2 - \beta^2R^2}} dx_1
\]  
(52c)

The magnitude of the additional volume wrapped around the cylinder is
\[
V_e = \int_0^l [S(x) - S(o)] dx
\]  
(53a)

and, from equation (52b),
\[
V_e = \frac{1}{U_0} \int_{-\beta R}^{l-\beta R} A_0(x_1) \frac{1}{\sqrt{(l - x_1)^2 - \beta^2R^2}} dx_1
\]  
(53b)

The variational problem. - The quantity to be minimized will be taken as \( D = \mu_1 V_e \). From equation (32), the drag can be written, after an integration by parts,
\[
D = \rho_0 \frac{\mu_1}{4\pi} \int_{-\beta R}^{l-\beta R} \frac{A_0(x_1) dx_1}{\sqrt{(l - x_1)^2 - \beta^2R^2}} \int_{-\beta R}^{l-\beta R} \frac{A_0'(x_2) \sqrt{(l - x_2)^2 - \beta^2R^2}}{x_1 - x_2} dx_2
\]  
(54)

In addition to prescribing the volume added to the fundamental cylinder, we shall also require that the body return at the end to the same cross-sectional area as at the front. Thus, according to equation (52b),
\[
0 = \int_{-\beta R}^{l-\beta R} \frac{(l - x_1)A_0(x_1) dx_1}{\sqrt{(l - x_1)^2 - \beta^2R^2}}
\]  
(55)
is a condition to be met by the minimizing function $A_0(x_1)$, and by its variations.

The quantity $D - \mu_1\nu_1e$ can be formed from equations (53) and (54), and if the variation is performed, one finds the condition

$$\int_{-\beta R}^{l-\beta R} \frac{\delta A_0(x_1)dx_1}{\sqrt{(l - x_1)^2 - \beta^2 R^2}} \left[ \int_{-\beta R}^{l-\beta R} \frac{A_0'(x_2)\sqrt{(l - x_2)^2 - \beta^2 R^2}}{x_1 - x_2} dx_2 - \frac{2\pi}{\rho_0 U_0} \mu[(l - x_1)^2 - \beta^2 R^2] \right] = 0$$

If this last equation is compared with equation (55), it is seen that for admissible variations, the quantity within the brackets must be set equal to $\lambda(l - x_1)$, where $\lambda$ is an arbitrary constant. Thus, the equation for determination of the optimizing source distribution under the conditions of given volume and closure is

$$\int_{-\beta R}^{l-\beta R} \frac{A_0'(x_1)\sqrt{(l - x_1)^2 - \beta^2 R^2}}{x - x_1} dx_1 = \lambda(l - x) + \frac{2\pi \mu_1}{\rho_0 U_0} [(l - x)^2 - \beta^2 R^2]$$

Equation (56) is recognized as the familiar airfoil equation with $[A_0'(x_1)\sqrt{(l - x_1)^2 - \beta^2 R^2}]$ as the unknown. Thus we write the solution immediately as (see, e.g., ref. 15)

$$A_0'(x_1)\sqrt{(l-x)^2-\beta^2 R^2} = \frac{1}{\pi \sqrt{(l-\beta R-x)(x+\beta R)}} \left\{ \pi \int_{-\beta R}^{l-\beta R} A_0'(x_1)\sqrt{(l-x_1)^2-\beta^2 R^2} dx_1 - \frac{\lambda(l-x_1) + \frac{2\pi \mu_1}{\rho_0 U_0} [(l-x_1)^2-\beta^2 R^2]}{x - x_1 \sqrt{(l-\beta R-x_1)(x_1+\beta R)}} dx_1 \right\}$$

The first integral on the right vanishes according to the closure condition (55) and, if the remaining integrations are performed, we find
It will be noted that unless
\[
\frac{2\pi l}{\rho_0 U_0} \mu_1 + 2\lambda = 0
\]
this solution for \( A_0'(x) \) does not obey the closure requirement. Therefore we impose this last condition and finally obtain
\[
A_0'(x) = \frac{\mu_1}{4\rho_0 U_0} \frac{(l^2 - 4\beta Rl - 8\beta^2 R^2) - 8l x + 8x^2}{\sqrt{(l + \beta R - x)(x + \beta R)}} \tag{57}
\]

The strength of the minimizing source distribution \( A_0(x) \) is now obtained by integrating equation (57);
\[
A_0(x) = \frac{\mu_1}{2\rho_0 U_0} \left[ (l - 2x)\sqrt{(l + \beta R - x)(x + \beta R)} - 2\beta^2 R^2 \cos^{-1} \frac{l - 2x}{l + 2\beta R} \right] \tag{58a}
\]

Properties of the optimal source distribution. It is convenient to express the various quantities such as source strength, area distribution, etc., as dimensionless functions of the dimensionless variable \( \eta = x/l \) and parameter \( \sigma = \beta R/l \). Thus, indicating a dimensionless function by a star, we have from equation (58a)
\[
A_0*(\eta) = \frac{A_0(2\eta)}{4\eta U_0} = \frac{\mu_1}{4\rho_0} \left[ (1 - 2\eta)\sqrt{(\eta + \sigma)(1 - \eta + \sigma)} - 2\sigma^2 \cos^{-1} \frac{l - 2\eta}{l + 2\sigma} \right] \tag{58b}
\]
It will be noted that if the radius of the control surface is taken very small, so that \( \sigma \to 0 \), formula (58b) becomes

\[
A_0^*(\eta) \big|_{\sigma \to 0} = \frac{\mu_{1l}}{4d_0} (1 - 2\sigma)\sqrt{\eta(1 - \eta)}
\]

which is the well-known slender-body theory result for the source distribution corresponding to an optimum body of given volume (refs. 16 and 17.)

In order to determine the value of the Lagrange multiplier \( \mu_1 \), in terms of the prescribed volume \( V_e \), it is convenient to find first the expression for the local cross-section area of the optimum body. Thus, using equation (52c) (with \( S^*(\eta) = \frac{1}{l^2} S(d) \)),

\[
S^*(\eta) - S^*(0) = \frac{\mu_{1l}}{6d_0} \sqrt{(\eta + 2\sigma)(1 - \eta + 2\sigma)[\eta(1 - \eta)E - \sigma(1 - 4\sigma)(K - E)]}
\]

where \( K \) and \( E \) are elliptic integrals of the first and second kinds, respectively, of modulus

\[
k^2 = \frac{\eta(1 - \eta)}{(\eta + 2\sigma)(1 - \eta + 2\sigma)}
\]

Using equation (59) in equation (53a), we find

\[
V_e^* = \frac{\mu_{1l}}{6d_0} \int_0^1 \sqrt{(\eta + 2\sigma)(1 - \eta + 2\sigma)[\eta(1 - \eta)E - \sigma(1 - 4\sigma)(K - E)]} d\eta
\]

\[
= \frac{\mu_{1l}}{6d_0} B(\sigma)
\]

which expresses the constant \( \mu_1 \), in terms of the prescribed volume \( V_e^* \) and of a function \( B \) of the quantity \( \sigma = \beta R / l \). A graph of this function \( B(\sigma) \) versus \( \sigma \) is shown in figure 1. Shown also in figure 1 is a dashed line that corresponds to the asymptotic form for \( B(\sigma) \), which is

\[
B(\sigma) \approx \frac{\pi}{16} \left( 1 + 4\sigma \right) \sqrt{\frac{2\sigma}{1 + 2\sigma}}
\]

The closeness of the asymptotic values to the exact values even for relatively small values of \( \sigma \) is noteworthy.
The formulae (58b) and (59) for the source strength and cross-section area, respectively, can now be recast in terms of prescribed quantities

\[ A_0^*(\eta) = \frac{3}{2} \frac{V_\text{e}^*}{B(\sigma)} \left[ (1 - 2\eta)\sqrt{\frac{(\eta + \sigma)(1 - \eta + \sigma)}{1 + 2\sigma}} - 2\sigma^2 \cos^{-1} \left( \frac{1 - 2\eta}{1 + 2\sigma} \right) \right] \]  

\[ \frac{S^*(\eta) - S^*(0)}{S^*(0)} = \frac{(V_\text{e}^*/V_0^*)}{B(\sigma)} \sqrt{(\eta + 2\sigma)(1 - \eta + 2\sigma)[\eta(1 - \eta)E - \sigma(1 - 4\sigma)(K - E)]} \]

where \( V_\text{e} \) is the volume of the original cylinder section,

\[ V_0 = \pi R^2 l = 2S(0) = \tau S V_0^* \]

Consider the expression (61) for the source function \( A_0^*(\eta) \). In the parameter \( \sigma = \beta R / l \), we may think of \( \beta \) as fixed and \( l \) as unity, so that variations in \( \sigma \) amount to variations in the size of the control surface of radius \( R \). Thus, in sketch (g), the case \( \sigma = 0 \) corresponds to the source distribution for the well-known Sears-Haack body (refs. 16 and 17). It will be noted in the cases where \( \sigma > 0 \) that the source functions become less steep and attain lesser maximum values because the
volume remains the same while the control-surface cylinder is increasing, thus giving a smaller maximum radius of the added portion.

Next let us examine the expression (62a) for cross-sectional area. First, we notice that it can be written

$$S^*(\eta) - S^*(0) = \frac{V_e^*}{B(\sigma)} \sqrt{(\eta + 2\sigma)(1 - \eta + 2\sigma)} [\eta(1 - \eta)E - \sigma(1 - 4\sigma)(1 - E)]$$  \hspace{1cm} (62b)

in which form it reduces formally for \( \sigma \rightarrow 0 \) to

$$S^*(\eta) = \frac{128}{3\pi} V_e^* \eta(1 - \eta)^{3/2}$$  \hspace{1cm} (62c)

which is identical with the expression for cross-section area of a slender optimum body of prescribed volume (Sears-Haack body). Of course, \( V_e \) is, in this case, the total volume of the body. On the other hand, if we allow the radius of the control surface to increase indefinitely, equation (62b) gives (using the asymptotic form for \( B(\sigma) \), eq. (60b))

$$S^*(\eta) - S^*(0) = 6V_e^* \eta(1 - \eta)$$

In the case when \( R \) is very large, we take

$$S(x) - S(0) = 2\pi R \Delta r(x)$$  \hspace{1cm} (63)

so we have, returning to the original variables,

$$\Delta r(x) = 6 \frac{V_e}{2\pi R l} \frac{x(l - x)}{l^2}$$  \hspace{1cm} (64)

where \( \frac{V_e}{2\pi R l} \) is a finite quantity, and, in fact, is the average height of the protuberance above the control cylinder. This result is clear from physical reasoning, for one would expect that as the control cylinder increased in radius, the two-dimensional result for the optimum problem would become more nearly valid, and, indeed, equation (64) is the formula for a two-dimensional biconvex section, where \( \Delta r \) is distance from the mean line, \( l \) is chord length, and maximum thickness is \( \left( \frac{3}{4} \frac{V_e}{\pi R l} \right) \).

It will be noted that the area distribution as given by equation (62b) has fore-and-aft symmetry, since the functional dependence upon \( \eta \) involves only the combination \( \eta(1 - \eta) \). The maximum cross-section of
the optimum body then occurs at the midpoint \( \eta = 1/2 \) and is given by (from eq. (62b))

\[
S_{\text{max}}^* - S^*(0) = 2V_e^* \frac{1 + 4\sigma}{4B(\sigma)} \left[ \frac{E}{4} - \sigma(1 - 4\sigma)(K - E) \right] = 2V_e^* T(\sigma) \tag{65}
\]

where the modulus of the elliptic integrals is now \( k = 1/(1 + 4\sigma) \). Sketch (h) shows the function \( T(\sigma) \) versus \( \sigma \).

![Sketch (h)](image)

The drag of the optimum bodies can now be evaluated. From equations (54) and (56)

\[
D = \frac{\rho_0}{4\pi} \int_{-\beta R}^{\beta R} \frac{A_0(\xi) d\xi}{\sqrt{(l - \xi)^2 - \beta^2 R^2}} \left\{ \lambda(l - \xi) + \frac{2\mu_1}{\rho_0 U_0} [(l - \xi)^2 - \beta^2 R^2] \right\}
\]

The integral involving \( \lambda \) vanishes because of the closure condition. The remaining integration gives

\[
D = \frac{\mu_1}{2U_0} \int_{-\beta R}^{\beta R} A_0(\xi) \sqrt{(l - \xi)^2 - \beta^2 R^2} d\xi = \frac{\mu_1 V_e}{2} \tag{66}
\]

by equation (53b). Finally, using the evaluation of \( \mu_1 \) of equation (60a), we have
Numerical results pertaining to the problem just solved will be given in a later section, and a summary of the important formulae is given in the Appendix.

Quasi-Cylindrical Body of Revolution With Given Caliber

The variational problem.- For this problem, we prescribe the area at the base of the body, so the given condition is, from equation (52b)

\[ \Delta S = S(l) - S(0) = \frac{1}{U_0} \int_{-\beta R}^{l-\beta R} \frac{(l - x_1)A_0(x_1)dx_1}{\sqrt{(l - x_1)^2 - \beta^2R^2}} \]  

(68)

The variation can be taken as before (now without invoking the closure condition) on the quantity \( D + \lambda \Delta S \), and it leads to the integral equation

\[ \int_{-\beta R}^{l-\beta R} \frac{A_0'(x_1)\sqrt{(l - x_1)^2 - \beta^2R^2}}{x - x_1} dx_1 = -\frac{2\pi\lambda}{\rho_0U_0} (l - x) \]  

(69)

The solution to equation (69) consistent with the given conditions is

\[ A_0'(x) = \frac{4}{\pi} \frac{U_0(\Delta S)}{l(l + 4\beta R)} \frac{l - 2x}{\sqrt{(l + \beta R - x)(x + \beta R)}} \]  

(70a)

Integrating this expression, we find for the strength of the optimizing source distribution

\[ A_0(x) = \frac{8}{\pi} \frac{U_0(\Delta S)}{l(l + 4\beta R)} \sqrt{(l + \beta R - x)(x + \beta R)} \]  

(70b)

The source distribution of equation (70b) represents the first approximation to the result of reference 3 for nearly equal front and rear radii.

Properties of the solution.- As in the section on the body with prescribed volume, we now consider \( x \) made dimensionless by division by \( l \),
and again set \( \sigma = BR/l \). The various quantities of interest in connection with the caliber problem then become

\[
A_{o^*}^*(\eta) = \frac{8}{\pi} \frac{\Delta S^*}{1 + 4\sigma} \sqrt{(\eta + \sigma)(1 - \eta + \sigma)}
\]

(70c)

\[
\frac{S^*(\eta) - S^*(\sigma)}{\Delta S^*} = \frac{2}{\pi(1 + 4\sigma)} \frac{(1 + 2\sigma)(1 + 4\sigma)\Pi(\sigma^2, k) - (1 - 2\eta)(\eta + 2\sigma)(1 - \eta + 2\sigma)E - (1 + 2\sigma)(1 - \eta + 2\sigma)K}{\sqrt{(\eta + 2\sigma)(1 - \eta + 2\sigma)}}
\]

(71)

where \( \Pi(\sigma^2, k) \) is a complete elliptic integral of third kind of modulus \( k^2 = \eta(1 - \eta)/(\eta + 2\sigma)(1 - \eta + 2\sigma) \) and parameter \( \sigma^2 = \frac{1 - \eta}{1 - \eta + 2\sigma} \). Again \( K \) and \( E \) are complete elliptic integrals of the first and second kinds, respectively, of the same modulus \( k \).

If we allow \( \sigma \) to approach zero, equation (71) becomes, in the limit,

\[
\frac{S^*(\eta)}{S^*(\sigma)} = \frac{2}{\pi} \left[ \sin^{-1}\sqrt{\eta} - (1 - 2\eta)\sqrt{\eta(1 - \eta)} \right]
\]

(72)

which is the shape function for the well-known Kármán ogive (ref. 18). At the other limit, when \( \sigma \to \infty \), equation (71) gives (in the original variables)

\[
\frac{S(x) - S(0)}{\Delta S} = \frac{x}{l}
\]

or, using the approximation of equation (63),

\[
\frac{\Delta r(x)}{\Delta r(l)} = \frac{x}{l}
\]

(73)

which is again the expected two-dimensional result for specified caliber.

The drag can be found by substituting equation (69) in equation (54), and then using equation (52b). There results
A summary of formulae pertaining to this body will be found in the Appendix.

Examples of Optimum Bodies

The optimum body of given volume. - In order to examine in detail the dependence of the body geometry on the parameter \( \sigma \), we may return to equation (62a). The quantity \([S^*(\eta) - S^*(0)]\) is actually the local cross-sectional area added to the basic cylinder by the action of the source distribution. In figure 2 are shown some cases of optimum bodies, having equal additional volume \( V_e \), for several values of the parameter \( \sigma \). Only half of each distribution is shown, since they are symmetric about the point \( \eta = 1/2 \). The one labeled \( \sigma = 0 \) is the Sears-Haack optimum body, and it will be noted that as \( \sigma \) increases, the curves depart rather quickly from this limiting case and approach the other limiting value of the biconvex distribution for \( \sigma \to \infty \). In fact, a biconvex arc drawn through the end points of the \( \sigma = 1/2 \) case is indistinguishable from the exact result in the scale used. In the inset of figure 2 is shown the variation of the drag of the optimum bodies as a function of \( \sigma \). This drag is also based on equal volume, and shows a fairly rapid decrease with increasing values of \( \sigma \), due to the decrease in the thickness of the exposed portion of the body. The dashed curve on the drag plot is the calculated drag \[
\frac{D}{\sigma_0 V_e / l^2} = \frac{12}{\pi \sigma}
\]
under the assumption that each meridian section of the body acts as an independent two-dimensional optimum airfoil. This admittedly crude approximation is of course very poor at low values of \( \sigma \), but its accuracy becomes surprisingly good for \( \sigma \) greater than about 0.4, and the approximation becomes exact in the limit \( \sigma \to \infty \).

The variation of local cross section with \( \sigma \) can be examined also on the basis of equal exposed area. Thus, using equation (65) in combination with equation (62b), we have

\[
\frac{\Delta S^*(\eta)}{\Delta S^*_{\text{max}}} = \frac{1}{2T(\sigma)B(\sigma)} \sqrt{(\eta + 2\sigma)(1 - \eta + 2\sigma)[\eta(1 - \eta)E - \sigma(1 - 4\sigma)(K - E)]}
\]

Figure 3 shows plots of equation (75), and it is again noted that the departure from the slender-body approximation (\( \sigma = 0 \)) is rapid. The limiting variation of area for \( \sigma \to \infty \) is also shown in figure 3, and it is seen again how closely the optimum body-shape functions approach this...
limiting result even for moderate values of $\sigma$. Also shown is the drag corresponding to these cases.

$$\frac{D}{q_0 l^2(\Delta S^*_{\text{max}})^2} = \frac{3}{4B(\sigma)[T(\sigma)]^2}$$

(76)

which shows a similar drop from the $\sigma = 0$ value as $\sigma$ is increased. Again, the effective fineness ratio of the bodies is increasing with $\sigma$, and, if frontal area exposed to the stream is held fixed, the maximum thickness of the excrescence vanishes as $1/\sigma$ for large $\sigma$. The departure of the geometric variation from the slender-body case is most pronounced near the nose, $\eta = 0$, where the slope is given by

$$\frac{dS^*(\eta)}{d\eta} = \frac{3\pi}{8} \frac{V e^*}{B(\sigma)} (1 + 4\sigma) \sqrt{\frac{2\sigma}{1 + 2\sigma}}$$

(77)

which vanishes only as $\sqrt{\sigma}$ for $\sigma \to 0$.

The optimum body of given caliber.- In this case, the maximum cross-section occurs at $\eta = 1$ so there is no longitudinal symmetry. Figure 4 shows, for several values of the parameter $\sigma$, the optimum, equal-caliber, incremental cross-section area given by equation (71). The inset shows the drag as a function of $\sigma$; from equation (74)

$$\frac{D}{q_0 \left( \frac{\Delta S}{l} \right)^2} = \frac{4}{\pi(1 + 4\sigma)}$$

Again in this case, the closeness of the optimum distributions as $\sigma$ increases to the two-dimensional value ($\sigma \to \infty$) is noticeable. This point has also been made by Ferrari in reference 5 where problems similar to ours are treated by a different approach. If the expression for cross-section area (eq. (71)) is expanded in powers of $1/\sigma$, it is found that

$$\frac{\Delta S^*(\eta, \sigma)}{\Delta S^*(1, \sigma)} = \eta - \frac{\eta(1 - \eta)(1 - 2\eta)}{32} \left( \frac{1}{\sigma} \right)^2 + \ldots$$

(78)

which shows the smallness of the correction to the two-dimensional result for moderate values of $\sigma$. 
Reciprocity Relations

The optimum body of given volume - The longitudinal and radial perturbation velocities can be determined by substituting the derivative of the source-distribution function (eq. (57)) into the formulae (29). We find, at any point \((x, r) \ (r \geq R)\) in the field

\[
\Phi(x, r) \over U_o = -\frac{\mu_1}{8\pi\rho_o} \frac{1}{\sqrt{[x + \beta(r + R)][1 - x + \beta(r + R)]}} \left\{ 4[x + \beta(r + R)][1 - x + \beta(r + R)]E + \\
[1(1 + 4\beta R) - 4(1 + 2\beta R)(1 - x + \beta r + \beta R)]K + 4(1 + 2\beta R)(1 - 2x)\Pi(\alpha^2, k) \right\} \quad (79a)
\]

\[
\Phi_r(x, r) = \frac{\mu_1}{8\pi\rho_o r} \frac{1}{\sqrt{[x + \beta(r + R)][1 - x + \beta(r + R)]}} \left\{ (1 - 2x)[x + \beta(r + R)][1 - x + \beta(r + R)]E - \\
\beta R(2x + 2\beta R - R)K - 4\beta^2 R(r - R)[1 - x + \beta(r + R)]K + \\
4\beta^2 (r^2 - R^2)(1 + 2\beta R)\Pi(\alpha^2, k) \right\} \quad (79b)
\]

where now

\[
\kappa = \frac{1}{\sqrt{[x + \beta(r + R)][1 - x + \beta(r + R)]}}
\]

\[
\alpha^2 = -\frac{1}{r} \frac{x - \beta(r - R)}{1 - x + \beta(r + R)}
\]

For the present axis system, the act of reversing the flow amounts to substituting \(l - x\) for \(x\), and, for the case of the symmetric body, the longitudinal perturbation velocity in the reversed flow is

\[
\tilde{u}(x, r) = -u(1 - x, r) = -\Phi_x(l - x, r)
\]

Now, from equation (40), pressure in the combined field is given by

\[
P = -\rho_o U_o (u + \tilde{u}) = -\rho_o U_o [\Phi_x(x, r) - \Phi_x(l - x, r)]
\]

(80)
Substituting equation (79a) into this relation, we find

\[ P = \frac{\mu_1}{2} (l - 2x) \]  

(81)

by using the addition formula for the elliptic integral of third kind. Differentiating equation (81) we find

\[ P' + \mu_1 = 0 \]  

(82)

which agrees with the criterion for minimum drag with given volume established in equation (47). The Lagrange multiplier \( \mu_1 \) is therefore identified as the pressure gradient in the combined flow field. It will be noted that equations (81) and (82) hold everywhere within the enveloping forward and rearward Mach cones of the quasi-cylindrical body (see sketch (d)).

Now considering the radial component of perturbation velocity \( \phi_r \), we find

\[ \frac{\phi_r(x,r)}{U_0} + \frac{\phi_r(l - x,r)}{U_0} = \frac{B^2(r^2 - R^2)}{4\omega_0r} \mu_1 \]  

(83)

so that the relation

\[ \phi_r(x,r) = -\phi_r(l - x,r) \]

is satisfied on the quasi-cylinder itself, that is, when we set \( r = R \).

The optimum body of given caliber. For this case we find the following equations for the perturbation velocities:

\[ \frac{\phi_k(x,r)}{U_0} = -\frac{\lambda (l + 2\beta R)}{2\pi \omega_0 \sqrt{\beta(x + (r + R))} \sqrt{\beta(x + (r + R))}} \left[ K - 2\Pi(a^2,k) \right] \]  

(84a)

\[ \frac{\phi_r(x,r)}{U_0} = -\frac{\lambda}{2\pi \omega_0 \sqrt{\beta(x + (r + R))} \sqrt{\beta(x + (r + R))}} \left\{ \left[ x + \beta(r + R) \right] \left[ 1 - x + \beta(r + R) \right] E - \beta r(1 + 2\beta R)K \right\} \]  

(84b)

where the elliptic integrals have the same modulus and parameter as in the previous section.
In this case, the pressure in the combined flow field is

\[ P = -\rho_0 U_0 [\varphi_x(x,r) + \varphi_x(l - x,r)] \]  

(85)

which gives

\[ P = \lambda \]  

(86)

so that in this instance, pressure itself is constant in the combined flow field.

From equation (84b), we see that

\[ \varphi_x(x,r) = \varphi_x(l - x,r) \]  

(87)

since the modulus of the elliptic integrals is invariant to the change \( x \rightarrow l - x \).

Uses of the reciprocity relations.- The reciprocity relations serve the dual function of checking the derived perturbation potential against minimization criteria based on other considerations (see eq. (47)) and of relating the Lagrangian multipliers to the pressure or pressure gradient in the combined flow field. Equations (81) and (86) also reveal that the expressions for pressure in the combined flow field hold, independently of \( r \), throughout the entire region within the enveloping cones of the bodies. These results are generalizations of a similar effect noted in reference 19, where the combined pressure field associated with a Sears-Haack body was shown to have a constant gradient within the enveloping cones. In the latter reference, this property of the minimum-drag body was used to expedite the calculation of interference drag with a satellite body lying within the enveloping cones. Similar methods could obviously be applied to the present configurations.

APPENDIX A

SUMMARY OF FORMULAE FOR THE OPTIMUM BODIES

The formulae derived in the text for the body shape function, pressure coefficient, and drag of optimum bodies having given volume or given caliber are repeated here for convenience. The type of configuration treated, and the nomenclature, are shown in sketch (Aa).

Sketch (Aa)

The Optimum Body of Given Volume

The variation of $AS$ for the optimum body with given volume is

$$\Delta S(x) = \frac{Ve}{\sqrt[4]{B(\frac{BR}{l})}} \sqrt{\frac{B(\frac{BR}{l})}{(x+2BR)(l-x+2BR)}} \left\{ x(l-x)E(k) - \beta R(l-4BR)[K(k)-E(k)] \right\}$$

(Al)

where

$\Delta S(x) = \pi[(R + \Delta x)^2 - R^2]$

$Ve$ = volume of exposed portion

$B(\frac{BR}{l}) = B(\sigma)$ function defined in equation (60a) and shown in figure 1

$K(k) = \text{complete elliptic integral of first kind of modulus } k$

$E(k) = \text{complete elliptic integral of second kind of modulus } k$

$k^2 = \frac{x(l-x)}{(x+2BR)(l-x+2BR)}$

Examples of optimum bodies for a few values of the parameter $\beta R/l$ are shown in figures 2 and 3.
The pressure coefficient on the body is

\[ C_p = \frac{p - p_o}{q_o} \]

\[ = -2 \frac{u}{U_o} \]

\[ = 3 \frac{V_e}{2\pi l^2 B (\frac{BR}{l})} \times \]

\[ \frac{4(x+2\beta R)(l-x+2\beta R)E-[l(l+4\beta R)-4(1+2\beta R)(l-x+2\beta R)]K}{\sqrt{(x+2\beta R)(l-x+2\beta R)}} \]

\[ \Pi(\alpha^2, k) \]

(A2)

where \( \Pi(\alpha^2, k) \) is a complete elliptic integral of third kind of modulus \( k \) and parameter \( \alpha^2 \) (in the notation of ref. 20). The parameter \( \alpha^2 \) is given by

\[ \alpha^2 = -\frac{x}{l-x+2\beta R} \]

Sketch (Ab) shows some plots of \( C_p/(V_e/l^3) \) versus \( x/l \) for a few values of the parameter \( \beta R/l \).
The wave drag of this optimum body is given by

\[ \frac{D}{d_o} = 3 \frac{V_e^2}{l^4 B \left( \frac{\beta R}{l} \right)} \]  

(A3)

The variation of drag with \( \beta R/l \) is shown in figures 2 and 3.

The Optimum Body of Given Caliber

The variation of \( \Delta S \) for the optimum body of given caliber is

\[ \Delta S(x) = \frac{2}{\pi} \frac{\Delta S(z)}{l(l+4\beta R)} \times \]

\[ \frac{l(l+2\beta R)(l+4\beta R) \Pi(\alpha^2, k) - (l-2x)(x+2\beta R)(l-x+2\beta R) E - l(l+2\beta R)(l-x+2\beta R) K}{\sqrt{(x+2\beta R)(l-x+2\beta R)}} \]  

(A4)

where the symbols have been defined above. Examples of optimum bodies for a few values of the parameter \( \beta R/l \) are shown in figure 4.

The pressure coefficient on the body is given by

\[ C_p = \frac{8}{\pi^2} \frac{\Delta S(z)}{l} \frac{l+2\beta R}{l+4\beta R} \frac{2\Pi(\alpha^2, k) - K}{\sqrt{(x+2\beta R)(l-x+2\beta R)}} \]  

(A5)
Sketch (Ac) shows some plots of $\frac{C_p}{\Delta S(l)/l^2}$ versus $x/l$ for several values of the parameter $\beta R/l$.

The drag of this body is

$$\frac{D}{q_0} = \frac{4}{\pi(l + 4\beta R)} \frac{[\Delta S(l)]^2}{l}$$

and its variation with $\beta R/l$ is shown in figure 4.
