LONGITUDINAL CHARACTERISTICS OF AN
UNSWEPT-WING FIGHTER-TYPE MODEL WITH EXTERNAL
STORES AT A MACH NUMBER OF 1.82 AND SOME EFFECTS
OF HORIZONTAL-TAIL AND YAW-DAMPER-VANE
DEFLECTION ON THE SIDESLIP DERIVATIVES

By Ross B. Robinson

SUMMARY

An investigation has been made in the Langley 4- by 4-foot super­
sonic pressure tunnel to determine the effects of the addition of one
body-mounted external store, tip tanks, and several tip-mounted missile
configurations on the aerodynamic characteristics in pitch of a fighter
model with a low-aspect-ratio, unswept wing at a Mach number of 1.82.
Limited tests were also made to obtain the interference effects of
horizontal-tail deflection on the sideslip derivatives, the control
characteristics of a yaw-damper vane, and the effects of a ventral fin
on the longitudinal characteristics.

The results indicated that the addition of any of the tip-mounted
store configurations to the basic model produced increased lift-curve
slopes and drag increments which decreased with increasing lift coef­
cient above lift coefficients of about 0.06. The body-mounted store
causd no change in the lift-curve slope of the basic model and resulted
in drag increments that increased with increasing lift coefficients. Of
all the store configurations tested, the external store arrangement
causing the least drag increment was the tip-mounted Sidewinder missile
configuration.

Negative deflection of the high horizontal tail decreased the direc­
tional stability and produced a smaller value of positive effective
dihedral.
Until recently there has been only a limited amount of experimental information on the aerodynamic characteristics of airplane configurations with low-aspect-ratio, unswept wings at supersonic speeds. The results of wind-tunnel tests to investigate various horizontal- and vertical-tail configurations of a fighter model having a low-aspect-ratio, unswept wing at Mach numbers of 1.35 to 1.90 are presented in references 1 and 2.

Among the problems of concern is the effect of the addition of external stores to unswept-wing aircraft at these Mach numbers. This report presents the results of an investigation to determine the effects of various external store and missile configurations on the aerodynamic characteristics in pitch at a Mach number of 1.82 of a fighter model with a low-aspect-ratio, unswept wing. Limited data are also given for the effects of a ventral fin on the longitudinal characteristics, for the effects of stabilizer deflection on the sideslip derivatives, and for the control characteristics of a yaw-damper vane. The tests were made in the Langley 4- by 4-foot supersonic pressure tunnel at a Reynolds number of $2.03 \times 10^6$, based on the mean geometric chord of the wing.

COEFFICIENTS AND SYMBOLS

The results of this investigation are presented as standard NACA forces and moments. The lift, drag, and pitching-moment coefficients are referred to the stability axis system and the side-force, rolling-moment, and yawing-moment coefficients are referred to the body axis system with the reference center of gravity at 25 percent of the wing mean geometric chord (fig. 1). The coefficients and symbols are defined as follows:

- $C_L$ lift coefficient, $F_L/qS$
- $C_D'$ approximate drag coefficient, $F_D'/qS$
- $C_m$ pitching-moment coefficient, $M_Y/qSc$
- $C_Y$ side-force coefficient, $F_Y/qS$
- $C_l$ rolling-moment coefficient, $M_X/qSb$
- $C_n$ yawing-moment coefficient, $M_Z/qSb

A three-view drawing of the basic configuration and the ventral fin is presented in figure 2. Sketches of the various store configurations are shown in figure 3. Photographs of several configurations are presented in figure 4. Geometric characteristics of the model and of the various stores are given in tables I and II.

The model was equipped with a wing having 18.5° sweep of the 0.25 chord line, aspect ratio 2.45, taper ratio 0.377, and 3.4-percent-thick modified biconvex airfoil sections. The wing was set at zero incidence to the fuselage reference line and had 10° of negative geometric dihedral. The fuselage was contoured to simulate faired side inlets.

Deflections of the stabilizer and yaw damper were set manually. The rudder deflection was zero degrees for all the tests.

The ventral fin was a thin aluminum plate with beveled edges fastened to the bottom of the body. The base of the fin was faired to approximate body contour. The yaw damper was a trailing-edge flap located below the rudder on the vertical tail (fig. 2).

External store arrangements investigated were: (a) a pylon-mounted body store (fig. 3(a)); (b) two fuel tanks, one on each wing tip (fig. 3(b)); (c) two Sidewinder missiles with mounts, one on each wing tip, (fig. 3(c)); (d) two Falcon missiles with mounts, one on each wing tip (fig. 3(d)); and (e) four Falcon missiles, two per wing tip, on end-plate-type mounts (fig. 3(e)).

Force and moment measurements were made through the use of a six-component internal strain-gage balance. Base static pressures were measured just inside the model base.

**TEST CONDITIONS AND PROCEDURE**

The conditions for the tests were:

- Mach number: 1.82
- Reynolds number, based on c: 2.03 x 10^6
- Stagnation dewpoint, °F: -20
- Stagnation pressure, lb/sq in., abs: 10
- Stagnation temperature, °F: 100
- Mach number variation: ±0.01
- Flow angle in horizontal or vertical plane, deg: ±0.1

CONFIDENTIAL
Tests were made through an angle-of-attack range of about $-3^\circ$ to about $+10^\circ$ at a sideslip angle of $0^\circ$ and through an angle-of-sideslip range of about $-3^\circ$ to about $11^\circ$ at an angle of attack of $5.2^\circ$. All tests were made with simulated faired side inlets. The effects of these fairings on the aerodynamic characteristics are not known but are believed to be small.

CORRECTIONS AND ACCURACY

The angle of attack and sideslip were corrected for the deflection of the balance and sting under load. No corrections were applied to the data to account for the tunnel flow variations. The drag data were adjusted by equating the base pressure to the free-stream static pressure.

Maximum probable errors in the data are:

- $C_L$: ±0.0066
- $C_D'$: ±0.0003
- $C_m$: ±0.0007
- $C_l$: ±0.003
- $C_n$: ±0.0001
- $C_Y$: ±0.0019
- $\alpha$, $\beta$, $i_t$, $\delta_r$, deg: ±0.1

RESULTS AND DISCUSSION

Effects of Various External Stores on the Aerodynamic Characteristics in Pitch

The aerodynamic characteristics in pitch for the basic configuration for $i_t = 0^\circ$ are shown in figure 5. The flagged symbols are data from a repeat run. The values of lift-curve slope and static longitudinal stability agree closely with the results shown in reference 1 for a similar configuration.

The effects of various store installations on the aerodynamic characteristics in pitch for $i_t = 0^\circ$ are presented in figure 6. Incremental drag coefficients for the various stores and the effects of the stores on lift-drag ratios are presented in figures 7 and 8, respectively. Addition of the body store produced larger incremental drag and lower...
lift-drag ratios throughout the positive lift range than any of the tip-mounted stores (figs. 7 and 8). All of the tip-mounted stores acted both as wing end plates and additional lifting surfaces, producing higher lift-curve slopes and decreasing drag increments with increasing lift coefficient above \( C_L \approx 0.06 \) (figs. 6(b) to 6(e), and fig. 7). Addition of the body-store configuration produced a slight shift in the lift curve with no change in lift-curve slope and indicated slightly increasing incremental drag with increasing lift (fig. 6(a)).

The static longitudinal stability and trim lift coefficients were practically the same for all configurations except for the body-store arrangement which had slightly greater stability and higher trim \( C_L \) than the basic model (fig. 6(a)) and the configuration with four tip-mounted Falcons which had somewhat less stability and a significantly smaller value of trim \( C_L \) than the basic model (fig. 6(e)). Of all the arrangements tested, the configurations with two Sidewinders and the two Falcons resulted in the smallest drag increments and the highest lift-drag ratios through the \( C_L \) range tested (figs. 7 and 8). Addition of two tip tanks or four Falcons to the basic configuration produced about the same drag increments and lift-drag ratios.

Although no sideslip tests were made for the configurations having external stores, some tests of a similar configuration at \( M = 2.01 \) (results unpublished) indicate that rather large decreases in directional stability might be anticipated for the body-mounted-store arrangement because of the forward position of the store relative to the airplane center-of-gravity location.

**Effect of Ventral Fin on Aerodynamic Characteristics in Pitch**

A previous investigation (results unpublished) of the directional characteristics of a similar configuration showed that a ventral fin materially increased the directional stability at high angles of attack. Model scale and instrumentation limitations did not permit evaluation of the effects of the fin on the longitudinal characteristics of this similar configuration. Addition of the fin to the present larger scale model indicated little effect on the aerodynamic characteristics in pitch except for an increase in \( C_D' \) of about 0.0010 (fig. 9).
Effect of Stabilizer Deflection on Aerodynamic Characteristics in Sideslip

A -8° deflection of the horizontal stabilizer of the basic model at α = 5.2° (fig. 10) produced a reduction in both the directional stability \( C_{n_{\beta}} \) and positive effective dihedral \( -C_{\gamma_{\beta}} \). These effects probably result from the reduction of the positive pressures on the high-pressure surface of the vertical tail in the region of the negative pressures propagated from the bottom surface of the horizontal tail. Unpublished results of tests of a swept high horizontal-vertical tail arrangement at \( M = 2.01 \) indicate the same effect, while other tests have shown that negative deflections of a low stabilizer have the opposite effects.

It might also be expected that deflections of the horizontal tail would cause changes in the rudder control characteristics, but sufficient tests were not made to determine this.

Effect of Deflection of the Yaw Damper

Deflecting the yaw damper -20° resulted in a practically constant increment of yawing-moment coefficient of about 0.0025 and a slightly negative increment in side-force coefficient throughout the angle-of-attack range investigated (fig. 11). Since the damper was below the rudder (fig. 2) and had both a small area and short moment arm with respect to the fuselage reference line, the values of rolling-moment coefficient produced were small.

CONCLUSIONS

An investigation of the effects of external stores, ventral fin drag, some horizontal-tail interference effects, and a yaw-damper control on an unswept-wing, fighter-type model at a Mach number of 1.82 has indicated the following conclusions:

1. The addition of any of the tip-mounted store configurations to the basic model produced increased lift-curve slopes and, for lift coefficients greater than about 0.06, drag increments which decreased with increasing lift coefficients. The body-mounted store caused no change in the lift-curve slope of the basic body and produced drag increments which increased slightly with increasing lift.
2. The addition of the Sidewinder missile configuration to the basic model produced the smallest drag increments and highest lift-drag ratios for any combination tested. The largest drag increments resulted from the addition of the body-store arrangement.

3. Negative deflection of the high horizontal stabilizer of the basic model resulted in decreased directional stability and a smaller value of positive effective dihedral.

4. A yaw-damper deflection of $-20^\circ$ produced a practically constant increment of yawing-moment coefficient of about 0.0025 through the lift-coefficient range tested for the basic model.
