REPORT 1044

THE METHOD OF CHARACTERISTICS FOR THE DETERMINATION OF SUPERSONIC FLOW OVER BODIES OF REVOLUTION AT SMALL ANGLES OF ATTACK

By Antonio Ferrari

SUMMARY

The method of characteristics has been applied for the determination of the supersonic-flow properties around bodies of revolution at a small angle of attack. The system developed considers the effect of the variation of entropy due to the curved shock and determines a flow that exactly satisfies the boundary conditions in the limits of the simplifications assumed. Two practical methods for numerical calculations are given.

INTRODUCTION

For the determination of aerodynamic properties of bodies of revolution at supersonic speeds, two methods have been used: a method that uses the small-disturbances theory and a method that uses the characteristics theory. Both methods are successful in the determination of the flow properties for bodies at zero angle of attack, but the precision of the small-disturbances theory decreases when a body of revolution at an angle of attack is considered.

For bodies of revolution having supersonic flow everywhere, the theory of characteristics can also be used at an angle of attack.

The method of characteristics for the determination of the flow field around bodies of revolution at an angle of attack was first used by Ferrari (reference 1) in 1936. Ferrari considers the flow as potential flow and develops a method for the analysis of the flow field around a body that in the approximation of potential flow appears to be general and can be applied to bodies of any shape and with any angle of attack. In the determination of the flow properties along the first characteristic surface from which the analysis starts, however, Ferrari analyzes the flow around a cone of revolution, and in this part of the analysis only small values of angle of attack are considered.

Sauer in 1942 (reference 2) considers the same problems and shows that, for small values of angle of attack, the analysis of the flow field around a body of revolution can be made by applying the characteristics method only in one meridian plane; and, therefore, Sauer uses characteristic lines in place of the characteristic surfaces considered by Ferrari. Sauer, in the development of his system, is interested essentially in the analysis of the flow around circular cones; and when the method is applied to bodies of revolution of shapes different from cones, the boundary conditions are no longer satisfied. The flow obtained from the solution used, also at small angles of attack, wets a body that is not a body of revolution. The body can be obtained from the body of revolution considered initially by curving its axis of symmetry. Sauer also assumes that the flow is potential flow. With this assumption, the flow must be considered as potential flow for the case of the body at zero angle of attack also; therefore, all the effects of entropy gradients are neglected.

The flow field around circular cones at small angles of attack has been analyzed in a more exact form by Stone and Ferrre. (See references 3 to 5.) In his analysis, Stone considers the flow as rotational flow and, therefore, takes into account the effect of entropy gradients on the velocity distribution. This effect exists only when the cone has an angle of attack and, at low Mach numbers, is small but of the same order as the effect of other parameters that are considered in the analysis. Ferrre considers correctly the entropy distribution at the surface of the cone and found the existence of a vortical layer at the surface of the cone across which the pressure does not change although density and velocity change.

Here, the method of characteristics is extended to the analysis of the flow field around a body of revolution at small angles of attack for the case of rotational flow. The effect of entropy gradients about bodies of revolution even at small angles of attack can be important because the entropy gradients that exist in the stream for small angles of attack are due to the variation of curvature of the shock existing at zero angle of attack also, together with the fact that the shock surface does not have axial symmetry with respect to the direction of the undisturbed velocity.

The method presented permits the determination of a flow that in the assumption of small angles of attack exactly satisfies the boundary conditions and, therefore, wets the body of revolution considered. This method is given in a form that permits its application to practical problems and requires either numerical or numerical and graphical calculations of the same type as the calculations used for the analysis of the flow around bodies at zero angle of attack. The method can be applied to cases in which the entropy variations can be neglected or are zero. In these cases the terms that contain the entropy variations become zero.

SYMBOLS

- cylindrical coordinates (fig. 1)
- polar coordinates (fig. 8)
- local velocity (function of \( z, y, \theta \))
- velocity components in cylindrical coordinates (\( u \) along z-axis, \( v \) along y-axis, and \( w \) normal to meridian plane)
- velocity components in polar coordinates (\( v_r, v_\theta, w \) normal to meridian plane, and \( w \) normal to meridian plane)
- limiting velocity corresponding to adiabatic expansion to zero pressure
- pressure
- density
- ratio of specific heats
- speed of sound \( (a^2 = \gamma \rho) \)
- angle of attack of body
- Mach angle \( (\sin \beta = \frac{a}{V}) \)
- angle between velocity \( V \) and z-axis
- angle between the axis of the cone tangent to the shock and the axis of the body at the apex of the cone tangent to the shock
- tangents to the characteristic surfaces in the meridian plane \( \theta = \text{Constant} \)
- velocity component normal to the shock surface
- velocity component along the generatrix of the cone tangent to the shock
- velocity component tangent to the cross section of the cone tangent to the shock
- angle between the tangent to the shock and the axis of the body
- entropy variation for unit mass normal to the streamline in the plane \( \theta = \text{Constant} \)
- normal to the surface of the shock
- coefficients defined by equations (24)
- coefficient defined by equation (41)
- coefficient defined by equation (45)
- coefficients defined by equations (55)
- coefficients defined by equations (60)
- radius of the hodograph diagram

Subscripts:
- \( 0 \) free-stream flow quantities
- \( 1 \) flow quantities for the condition of zero angle of attack
- \( 2 \) flow quantities related to the effect of angle of attack as defined in equations (5) and (11)

**EQUATION OF MOTION FOR FLOW AROUND A BODY OF REVOLUTION AT A SMALL ANGLE OF ATTACK**

Consider a cylindrical coordinate system in which the z-axis is coincident with the axis of the body of revolution, the y-axis is normal to the z-axis in any meridian plane, and the position of every meridian plane is defined by the angle \( \theta \) measured with respect to the meridian plane that contains the direction of the undisturbed velocity (fig. 1).

Euler’s equations of motion for steady flow in cylindrical coordinates are

\[
\frac{1}{\rho} \frac{\partial \rho}{\partial t} = \frac{\partial}{\partial x} \left( \rho u \right) + \frac{\partial}{\partial y} \left( \rho v \right) + \frac{\partial}{\partial z} \left( \rho w \right) = \frac{1}{\rho} \frac{\partial p}{\partial x} + \frac{\partial}{\partial y} \left( \rho u \right) + \frac{\partial}{\partial z} \left( \rho w \right) + \frac{1}{\rho} \frac{\partial p}{\partial y} \frac{\partial \rho}{\partial y} + \frac{1}{\rho} \frac{\partial p}{\partial z} \frac{\partial \rho}{\partial z} = \frac{1}{\rho} \frac{\partial p}{\partial x} \frac{\partial \rho}{\partial x} + \frac{1}{\rho} \frac{\partial p}{\partial y} \frac{\partial \rho}{\partial y} + \frac{1}{\rho} \frac{\partial p}{\partial z} \frac{\partial \rho}{\partial z} \tag{1a}
\]

\[
\frac{1}{\rho} \frac{\partial \rho}{\partial t} = \frac{\partial}{\partial x} \left( \rho u \right) + \frac{\partial}{\partial y} \left( \rho v \right) + \frac{\partial}{\partial z} \left( \rho w \right) = \frac{1}{\rho} \frac{\partial p}{\partial x} + \frac{\partial}{\partial y} \left( \rho u \right) + \frac{\partial}{\partial z} \left( \rho w \right) + \frac{1}{\rho} \frac{\partial p}{\partial y} \frac{\partial \rho}{\partial y} + \frac{1}{\rho} \frac{\partial p}{\partial z} \frac{\partial \rho}{\partial z} = \frac{1}{\rho} \frac{\partial p}{\partial x} \frac{\partial \rho}{\partial x} + \frac{1}{\rho} \frac{\partial p}{\partial y} \frac{\partial \rho}{\partial y} + \frac{1}{\rho} \frac{\partial p}{\partial z} \frac{\partial \rho}{\partial z} \tag{1b}
\]

\[
\frac{1}{\rho} \frac{\partial \rho}{\partial t} = \frac{\partial}{\partial x} \left( \rho u \right) + \frac{\partial}{\partial y} \left( \rho v \right) + \frac{\partial}{\partial z} \left( \rho w \right) = \frac{1}{\rho} \frac{\partial p}{\partial x} + \frac{\partial}{\partial y} \left( \rho u \right) + \frac{\partial}{\partial z} \left( \rho w \right) + \frac{1}{\rho} \frac{\partial p}{\partial y} \frac{\partial \rho}{\partial y} + \frac{1}{\rho} \frac{\partial p}{\partial z} \frac{\partial \rho}{\partial z} \tag{1c}
\]

The continuity equation in cylindrical coordinates can be expressed in the form

\[
\frac{\partial (\rho u)}{\partial x} + \frac{\partial (\rho v)}{\partial y} + \frac{\partial (\rho w)}{\partial z} = 0 \tag{2}
\]

whereas the law of conservation of energy can be written in the form

\[
\frac{\gamma}{\gamma - 1} \left( \frac{1}{\rho} \frac{\partial p}{\partial x} - \frac{p}{\rho^2} \frac{\partial^2 \rho}{\partial x^2} \right) = -\left( \frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} + \frac{\partial w}{\partial z} \right) \tag{3a}
\]

\[
\frac{\gamma}{\gamma - 1} \left( \frac{1}{\rho} \frac{\partial p}{\partial y} - \frac{p}{\rho^2} \frac{\partial^2 \rho}{\partial y^2} \right) = -\left( \frac{\partial u}{\partial y} + \frac{\partial v}{\partial y} + \frac{\partial w}{\partial z} \right) \tag{3b}
\]

\[
\frac{\gamma}{\gamma - 1} \left( \frac{1}{\rho} \frac{\partial p}{\partial z} - \frac{p}{\rho^2} \frac{\partial^2 \rho}{\partial z^2} \right) = -\left( \frac{\partial u}{\partial z} + \frac{\partial v}{\partial y} + \frac{\partial w}{\partial z} \right) \tag{3c}
\]
BODIES OF REVOLUTION AT SMALL ANGLES OF ATTACK

If the density is eliminated from equation (2) by means of equations (1) and (3) and the quantity $a$ is introduced as defined by

$$ a^2 = \gamma \frac{P}{\rho} $$

the following equation can be obtained:

$$ \frac{\partial u}{\partial x} \left(1 - \frac{u^2}{a^2}\right) + \frac{\partial v}{\partial y} \left(1 - \frac{v^2}{a^2}\right) + \frac{\partial w}{\partial \theta} \left(1 - \frac{w^2}{a^2}\right) + \frac{v}{y} \frac{\partial v}{\partial \theta} + \frac{w}{y} \frac{\partial w}{\partial \theta} = 0 $$

Equation (6) is similar in form to the corresponding equation for the case of the body at zero angle of attack and differs only in the term $\frac{\partial w}{y \partial \theta}$. In order to analyze the differences between this expression and the expression for the axial symmetrical case and in order to obtain another relation that defines the quantity $w$, the relation between rotation of the flow and entropy gradient will now be introduced.

Between rotation of flow and entropy the following relation exists:

$$ \text{curl} \mathbf{V} \times \mathbf{V} = \frac{a^2}{\gamma R} \text{grad} S $$

or for small angles of attack

$$ \frac{\partial S}{\partial x} \frac{a^2}{\gamma R} = - \nu \left( \frac{\partial v}{\partial x} \frac{\partial u}{\partial y} \right) $$

$$ \frac{\partial S}{\partial y} \frac{a^2}{\gamma R} = \nu \left( \frac{\partial u}{\partial y} \frac{\partial u}{\partial y} \right) $$

$$ \frac{\partial S}{\partial \theta} \frac{a^2}{\gamma R} = \nu \left( \frac{\partial w}{\partial y} \frac{\partial u}{\partial y} + \frac{w v}{y} \frac{\partial w}{\partial y} - \frac{u v}{y} \frac{\partial w}{\partial \theta} \right) $$

If $n$ is the normal, in the meridian plane $\theta = \text{Constant}$, to the local tangent to the streamline, then

$$ \frac{\partial S}{\partial n} = - \frac{\partial S}{\partial x} \frac{\partial v}{\partial y} + \frac{\partial S}{\partial y} \frac{\partial u}{\partial y} $$

$$ = \frac{\gamma R}{a^2} \frac{\partial v}{\partial x} $$

whereas from equation (8c), when equations (6) are used, it follows that

$$ \frac{1}{a^2} \frac{\partial S}{\partial x} = \left[ \nu \left( \frac{\partial w}{\partial y} + \frac{v w}{y} \right) + \frac{w v}{y} + u \left( \frac{\partial w}{\partial y} + \frac{\partial w}{\partial \theta} \right) \right] \alpha \sin \theta $$

Therefore, the entropy can be expressed in the form

$$ \Delta S = \Delta S_1 + \alpha \Delta S_2 \cos \theta $$

where $\Delta S_1$ and $\Delta S_2$ are functions only of $x$ and $y$. Equation (11) is valid outside of the vortical layer existing at the surface of the body (see reference 5); whereas the entropy at the surface of the body is constant and equal to the value existing at the conical tip. Because no pressure gradient exists across the vortical layer, the pressure will be determined outside of the layer and equation (11) will be used in all the flow field. The presence of the layer must be considered for the velocity and density distribution at the surface of the body. At the surface of the body the entropy is constant and equal to $\Delta S_1 - \alpha \Delta S_2$. (The meridian plane $\theta = 0$ is defined as in figure 1.) From equation (11) it results

$$ \frac{\partial w}{\partial y} + u = \frac{\partial w}{\partial y} + \frac{v w}{y} + \frac{w v}{y} + u \left( \frac{\partial w}{\partial y} + \frac{\partial w}{\partial \theta} \right) \Delta S_2 $$

Equation (6) can be written in the following form:

$$ \frac{\partial u}{\partial x} \left(1 - \frac{u^2}{a^2}\right) + \frac{\partial v}{\partial y} \left(1 - \frac{v^2}{a^2}\right) + \frac{\partial w}{\partial \theta} \left(1 - \frac{w^2}{a^2}\right) + \frac{v}{y} \frac{\partial v}{\partial \theta} + \frac{w}{y} \frac{\partial w}{\partial \theta} = 0 $$

Equation (6) can be written in the following form:
Equation (13) together with equation (12) defines the law of motion of the flow around the body at small angles of attack. These equations will be used as a basis for the calculation of the flow field by the method of characteristics to be treated in a subsequent section.

CONDITIONS AT THE SHOCK FRONT

Equations (5) and (11) represent a stream that wets a body of revolution at a small angle of attack. In order to satisfy the boundary conditions at the surface of the body, the functions $u$, $v$, and $w$ must be properly selected. Equations (5) and (11) must, however, satisfy the boundary conditions at the shock surface also in order to be a solution of the problem. It is necessary, therefore, to show that a shock surface can exist across which the undisturbed stream inclined at $\alpha$ with respect to the axis of the body is transformed into a flow represented by equations (5) and (11). In order to show that the shock boundary conditions can be satisfied, the following procedure will be employed. A shock surface distorted in a manner to be described is assumed. Then, the free-stream velocity ahead of the shock will be resolved into three components: $v_{\eta}$ normal to the shock in the plane $\theta=$Constant, $v_{\rho}$ tangent to the shock in the plane $\theta=$Constant, and $w$ perpendicular to the plane $\theta=$Constant. Similarly, the flow behind the shock will be resolved into three components. In addition, each component of the flow behind the shock will be divided into two terms: one term for zero angle of attack and one term for the difference due to the angle of attack (for example, $u=u_0+\alpha u_0 \cos \theta$). Then, the conditions of equilibrium at the shock will be imposed, and it will be shown that the terms $u_\eta$, $v_\rho$, and $w_\eta$ at the shock are independent of $\theta$ when the angle of attack is small as initially assumed; hence, the distorted shock is consistent with the flow behind it. Such a shock surface can be obtained by deforming the shock surface produced by the body when the angle of attack $\alpha$ is zero in the following way (fig. 2):

When $\alpha=0$, the shock surface is a surface of revolution in axis with the body; therefore, if $OP, OP'$ is the curve intersection of the shock with the meridian plane $\theta=0$, then for $\alpha=0$ the tangent AQ at any point Q of the curve OP is the generatrix of a circular cone having the vertex at a point $A$ of the axis and tangent along the circle QQ' to the shock surface. The shock surface, therefore, can be considered as a surface envelope of circular cones having the axis coincident with the axis of the body but having variable cone angle and variable position of the apex $A$ along the axis $AB$ of the body. For the case of $\alpha \neq 0$ the shock surface is not a surface of revolution but can still be considered, for small angles of attack, as the envelope of the same circular cones considered for the case $\alpha=0$. These cones have the same apexes and the same cone angles as the cases for $\alpha=0$ but do not have the axis of symmetry AB coincident with the axis of the body AB although they are rotated in the plane $\theta=0$ with respect to the body axis. The angle $\eta$, through which each axis of the cones must rotate in the plane $\theta=0$ with respect to the axis of the body, is not constant but varies for each cone considered. For example, the cone AQQ' tangent to the shock surface for $\alpha=0$, when $\alpha \neq 0$, must be rotated by an angle $\eta$ to the position AQQ'; the axis AB remains in the plane $\theta=0$.

The shock surface so generated is consistent with the flow represented by equations (5) and (11), and this can be shown in the following way:

Consider a point $P$ of the shock produced by the body at an angle of attack, and consider the cone tangent to the shock at the point $P$ (fig. 3). Call $\sigma$ the semiangle of the cone with respect to its axis of symmetry. The axis of this cone is inclined at an angle $\eta$ with respect to the axis of the body and lies in the plane $\theta=0$.

The uniform velocity $V_0$ ahead of the shock is decomposed in the three components: $v_{\eta}$ in the direction PB normal to the shock, $v_{\rho}$ in the direction AP along the generatrix of the cone, and $w'$ in the direction normal to the plane APB. These components are, at small angles of attack, $v_{\eta}'=V_0 \sin \sigma - V_0 (\alpha - \eta) \cos \sigma \cos \theta$ (14a) $v_{\rho}'=V_0 \cos \sigma + V_0 (\alpha - \eta) \sin \sigma \cos \theta$ (14b) $w'=-V_0 (\alpha - \eta) \sin \theta$ (14c)

Strictly, in equations (14) $\psi$ must be written in place of $\theta$; but, for small angles of attack in equations (14), the difference between $\psi$ and $\theta$ can be neglected. Indeed, $\psi=\delta+\theta'$ where $\delta$ is of the order of $\alpha$, and $\theta'$ differs from $\theta$ by a quantity of the order of $\alpha$.
The velocity components behind the shock are (fig. 3)
\[ v''_x = u \sin \sigma - v \cos \sigma + \eta \cos \theta (v \sin \sigma + u \cos \sigma) \tag{15a} \]
\[ v''_y = u \cos \sigma + v \sin \sigma + \eta \cos \theta (v \cos \sigma - u \sin \sigma) \tag{15b} \]
\[ w'' = w + \eta (u - \delta \cot \sigma) \sin \theta \tag{15c} \]
where \( u, v, \) and \( w \) are the velocity components behind the shock in cylindrical coordinates in axis with the body at the point \( P \) considered.

The velocity components \( u, v, \) and \( w \) at the point \( P \) can be expressed in the form given by equations (5), in which the components \( u_1 \) and \( v_1 \) are the quantities obtained at the point \( P \) for the condition of \( \alpha = 0 \) and are direct functions only of \( x \) and \( y \). The point \( P \), however, is a point of the shock, and its coordinates \( x \) and \( y \) change when the coordinate \( \theta \) changes; therefore, the velocity components \( u_1 \) and \( v_1 \) at \( P \) also change with \( \theta \). In order to separate the part of the components \( u, v, \) and \( w \) dependent on \( \theta \) from the part independent of \( \theta \), the velocity components \( u_1 \) and \( v_1 \) at \( P \) will now be expressed as a function of the flow properties at a point \( P_1 \) near \( P \), having a constant value of \( x \) and \( y \) for every value of \( \theta \).

Now, it has been assumed that the angle of the cone \( \sigma \) tangent to the shock at the point \( P \) is equal to the angle of the cone tangent to the shock for the condition of zero angle of attack at the point \( P_1 \) (fig. 4). The point \( P_1 \) is obtained on the shock by rotating the cone \( APQ \) tangent to the shock for the condition \( \alpha = 0 \) through an angle \( \gamma \) around the axis \( AN \) normal to the plane \( \theta = 0 \) at the apex \( A \) of the cone. Because for the condition of zero angle of attack the velocity components \( u_1 \) and \( v_1 \) are independent of the coordinate \( \theta \), the velocity components \( u_1 \) and \( v_1 \) at \( P \) (fig. 4) are equal to the velocity components at \( P_1 \) for the case of a small angle of attack in the plane \( AP_1 C \). Therefore, if \( \Delta N \) is the distance \( P_1 P \),
\[ u_{1p} = u_1 + \frac{\partial u_1}{\partial N} \Delta N \tag{16a} \]
\[ v_{1p} = v_1 + \frac{\partial v_1}{\partial N} \Delta N \tag{16b} \]
where (fig. 4)
\[ \Delta N = \frac{x_{P1} \eta}{\cos \sigma} \tag{17} \]
Substituting equations (5), (16), and (17) in equations (15) results in
\[ v''_x = (u_1 \sin \sigma - v_1 \cos \sigma)_{P1} + \alpha \cos \theta (u_1 \sin \sigma - v_1 \cos \sigma)_{P1} + \eta \cos \theta (u_1 \sin \sigma - v_1 \cos \sigma)_{P1} + \frac{x_{P1} \eta}{\cos \sigma} \cos \theta \left( \frac{\partial u_1}{\partial N} \sin \sigma - \frac{\partial v_1}{\partial N} \cos \sigma \right)_{F1} \tag{18a} \]
\[ v''_y = (u_1 \cos \sigma + v_1 \sin \sigma)_{P1} + \alpha \cos \theta (u_2 \cos \sigma + v_2 \sin \sigma)_{P1} - \eta \cos \theta (u_1 \sin \sigma - v_1 \cos \sigma)_{P1} + \frac{x_{P1} \eta}{\cos \sigma} \cos \theta \left( \frac{\partial u_1}{\partial N} \cos \sigma + \frac{\partial v_1}{\partial N} \sin \sigma \right)_{F1} \tag{18b} \]
\[ w'' = \omega w_{1p} \sin \theta + \eta (u_1 - \delta \cot \sigma)_{P1} \sin \theta \tag{18c} \]

For the condition of zero angle of attack at \( P_1 \)
\[ v''_x^{N1} = u_1 \sin \sigma - v_1 \cos \sigma \tag{19a} \]
\[ v''_y^{N1} = u_1 \cos \sigma + v_1 \sin \sigma \tag{19b} \]
and for the condition of the equilibrium at the shock at zero angle of attack
\[ V_0 \cos \sigma = v''_x^{N1} \tag{20a} \]
\[ V_0 \sin \sigma = \frac{\gamma - 1}{\gamma + 1} \left( V''_x^{N1} - v''_y^{N1} \right) \tag{20b} \]

At the point \( P \) for the case of a small angle of attack,
\[ (v''_x^{N1}/v''_y^{N1})_{P} = \frac{\gamma - 1}{\gamma + 1} \left( V''_x^{N1} - v''_y^{N1} \right) \tag{21a} \]
\[ v''_x^{P} = \omega v''_x^{N1} \tag{21b} \]
\[ w'' = w' \tag{21c} \]

If equations (19) are used, equations (18a) and (18b) can be written in the form
\[ (v''_x^{N1})_{P} = (v''_x^{N1})_{P1} + \alpha \cos \theta (v''_x^{N1})_{P1} + \eta \cos \theta (v''_x^{N1})_{P1} + \frac{x_{P1} \eta}{\cos \sigma} \cos \theta \left( \frac{\partial v''_x^{N1}}{\partial N} \right)_{F1} \tag{22a} \]
\[ (v''_y^{N1})_{P} = (v''_y^{N1})_{P1} + \alpha \cos \theta (v''_y^{N1})_{P1} - \eta \cos \theta (v''_y^{N1})_{P1} + \frac{x_{P1} \eta}{\cos \sigma} \cos \theta \left( \frac{\partial v''_y^{N1}}{\partial N} \right)_{F1} \tag{22b} \]

Therefore, from equations (14), (20), and (21),
\[ - (\alpha - \eta) V_0 \cos \sigma (v''_x^{N1})_{P1} \]
\[ V_0 \sin \sigma \left( \frac{\alpha v''_x^{N1} + \eta v''_y^{N1} + x_{P1} \eta \frac{\partial v''_y^{N1}}{\sin \sigma} \sin \theta}{\sin \sigma \frac{\partial N}{N}} \right)_{F1} \]
\[ = \frac{2(\gamma - 1)(\alpha - \eta)}{\gamma + 1} \left( V_0 \cos \sigma \sin \sigma \right) \tag{22a} \]
\[ (\alpha - \eta) V_0 \sin \sigma = (v''_x^{N1})_{P1} - \eta (v''_y^{N1})_{P1} + \frac{x_{P1} \eta}{\sin \sigma} \left( \frac{\partial v''_y^{N1}}{\sin \sigma} \right)_{F1} \tag{22b} \]
or
\[
\left( \frac{v_{x}'''}{V_0} \right)_{P_1} = \left(1 - \frac{\eta}{\alpha} \right) \sin \sigma + \frac{\eta}{\alpha} \left( \frac{v_{x}'''}{V_0} \right)_{P_1}
\]
\[
- \frac{\eta}{\alpha} \frac{x_{P_1}}{V_0} \left( \frac{\partial v_{x}'''}{\partial N} \right)_{P_1}
\]
(23a)

or
\[
\left( \frac{v_{y}'''}{V_0} \right)_{P_1} = \tan \sigma \left[ -2 \left( \frac{\gamma - 1}{\gamma + 1} \right) \left(1 - \frac{\eta}{\alpha} \right) \sin \sigma + \left( \frac{1}{\alpha} \right) \frac{v_{y}'''}{V_0} \right]
\]
\[
- \frac{\eta}{\alpha} x_{P_1} \sin \sigma - \frac{\eta}{\alpha} \frac{x_{P_1}}{V_0} \left( \frac{\partial v_{y}'''}{\partial N} \right)_{P_1}
\]
(23b)

or
\[
\left( \frac{w_{z}}{V_0} \right)_{P_1} = -\left(1 - \frac{\eta}{\alpha} \right) + \left( - \frac{w_{z} + \frac{\alpha x_{P_1} \cot \sigma}{V_0} }{V_0} \right)
\]
(23c)

In equations (23) the coordinate \( \theta \) does not appear; therefore, for the shock considered the functions \( u_2, v_2, \) and \( w_2 \) are independent of \( \theta \), and equations (5) represent a flow condition in agreement with the conditions at the shock.

The ratio \( \eta/\alpha \) which appears in equations (23) is independent of \( \alpha \); therefore, for a given point \( P_1 \), \( \eta/\alpha \) remains constant in all the range of angle of attack in which the simplifications assumed are valid. (Indeed, \( u_2, v_2, \) and \( w_2 \) are also independent of the angle of attack (equations (5)). The values of \( u_2, v_2, \) and \( w_2 \) and \( \eta/\alpha \) must therefore be determined only for one value of the angle of attack.

METHOD OF CHARACTERISTICS FOR FLOW AROUND A BODY OF REVOLUTION AT A SMALL ANGLE OF ATTACK

In this section the method of characteristics is applied to equation (13) to establish equations which will permit the flow field behind the shock to be calculated by a point-by-point process. If the flow is anywhere supersonic, equations (12) and (13) permit the determination of the flow around a body of revolution at a small angle of attack by using the method of characteristics. Equation (13) can be written in the following form:

\[
H \frac{\partial u}{\partial x} + L \frac{\partial v}{\partial y} + 2K \frac{\partial v}{\partial x} + Z = 0
\]

where

\[
H = 1 - \frac{u^2}{a^2}
\]
\[
L = 1 - \frac{v^2}{a^2}
\]
\[
K = \frac{uv}{a^2}
\]
\[
Z = \frac{uu}{V} \left( \gamma \frac{1}{\gamma - 1} \frac{\partial S}{\partial n} + \frac{\partial w}{\partial \theta} + \frac{v}{y} \right)
\]

If \( \phi \) is the angle between the velocity \( V \) and the \( x \)-axis and \( \beta \) is the Mach angle,

\[
\tan \phi = \frac{\sqrt{\dot{V}^2 + \dot{u}^2}}{u}
\]
\[
\sin \beta = \frac{a}{V}
\]

or for small angles of attack

\[
\tan\phi = \frac{v}{u}
\]

and

\[
\sin\beta = \frac{a}{\sqrt{\dot{V}^2 + \dot{u}^2}}
\]

The tangent to the line intersection of a characteristic surface with the meridian plane \( \theta = \text{Constant} \) is

\[
\lambda_0 = \tan (\phi + \beta) = \frac{K}{H} - \frac{1}{H} \sqrt{K^2 - HL}
\]
\[
\lambda_0 = \tan (\phi - \beta) = \frac{K}{H} - \frac{1}{H} \sqrt{K^2 - HL}
\]

where \( \lambda_0 \) is the tangent to a line corresponding to the characteristic surface of the first family and \( \lambda_0 \) is the tangent to a line corresponding to the characteristic surface of the second family. The terms \( \lambda_0 \) and \( \lambda_0 \) are solutions of the equations (reference 6)

\[
Hx^2 - 2Kx + L = 0
\]

Because \( u, v, V, \) and \( a \) can be considered to be given by an equation of the type of equations (5), \( \phi \) and \( \beta \) can also be written in the form

\[
\phi = \phi_0 + \alpha \phi_1 \cos \theta
\]
\[
\beta = \beta_0 + \alpha \beta_1 \cos \theta
\]

The characteristic surfaces are not, therefore, surfaces of revolution but can be obtained, as was true for the case of the shock, as an envelope of circular cones with their apexes at the axis of the body and their axis of symmetry in the plane \( \theta = 0 \) and inclined with the axis of the body.

The determination of the \( u \) and \( v \) components of the velocity in any point of the flow can be obtained from equation (13) by performing a transformation in order to obtain a law of variation along the characteristic lines (reference 6). Indeed, for every point of any meridian plane (for example, of the meridian plane \( \theta = 0 \), or \( \theta = \pi \)) two characteristic lines can be obtained as the intersection of two characteristic surfaces with the meridian plane. Along these lines the variation of the \( u \) and \( v \) velocity components is determined by the equations of characteristics that can be derived from equation (13). Assume that at two points \( P_1 \) and \( P_2 \) (fig. 5) of the meridian plane \( \theta = \text{Constant} \) (for example, \( \theta = 0 \), or \( \theta = \pi \)) the velocity components are known. From equations (25) the tangents to the characteristic surfaces in this meridian plane can be drawn and the velocity components \( u \) and \( v \) at the point \( P_2 \), intersection of the two tangents, can be obtained in the first approximation.

The equations of characteristics can be obtained by analyzing equation (13) along the characteristic lines given by equation (25) in the following way: If \( du \) and \( dv \) are the variations along the characteristic lines,

\[
\frac{du}{dx} = \frac{\partial u}{\partial x} + (\lambda_0, \lambda_0) \frac{\partial u}{\partial y}
\]
or (see equation (9))

\[
\frac{du}{dx} = \frac{\partial v}{\partial x} + (\lambda_1, \lambda_2) \frac{\partial v}{\partial x} - (\lambda_1, \lambda_2) a_\theta \frac{\partial S}{\partial n}
\]

then

\[
\frac{dv}{dx} = \frac{\partial v}{\partial x} + (\lambda_1, \lambda_2) \frac{\partial v}{\partial y}
\]

If equations (27a) and (27b) are substituted in equation (12) and equation (26) is used, along the characteristic line of the first family defined by

\[
\frac{dy}{dx} = \lambda_1 = \tan (\beta + \phi)
\]

there results

\[
\frac{du}{dx} + \lambda_1 \frac{dv}{dx} = \frac{a_z}{\gamma R V} \frac{dS}{dn} \left( \frac{K}{H} - \lambda_1 \right) + \left( \frac{\partial \omega}{\partial x} + \frac{\partial \omega}{\partial y} \right) \frac{1}{H} = 0
\]

and along the characteristic line of the second family defined by

\[
\frac{dy}{dx} = \lambda_2 = \tan (\phi - \beta)
\]

there results

\[
\frac{du}{dx} + \lambda_2 \frac{dv}{dx} = \frac{a_z}{\gamma R V} \frac{dS}{dn} \left( \frac{K}{H} - \lambda_2 \right) + \left( \frac{\partial \omega}{\partial x} + \frac{\partial \omega}{\partial y} \right) \frac{1}{H} = 0
\]

Equations (28b) and (28d) contain the term \(\frac{\partial \omega}{\partial \theta}\), but at small angles of attack

\[
\frac{\partial \omega}{\partial \theta} = \frac{w_\theta}{y} \cos \theta = \frac{w}{y} \cos \theta
\]

and, therefore, \(\frac{\partial w}{y \partial \theta}\) is known at the points \(P_1\) and \(P_2\). The value of the entropy is also known at the points \(P_1\) and \(P_2\) and, therefore, the value of \(\frac{dS}{dn}\) can be determined (reference 6)

\[
\frac{dS}{dn} = \frac{\Delta S_{P_3} - \Delta S_{P_1}}{(x_{P_3} - x_{P_1}) \left[ \frac{\sin \beta}{\cos (\beta + \phi)} \right]_P + (x_{P_3} - x_{P_2}) \left[ \frac{\sin \beta}{\cos (\phi - \beta)} \right]_P}
\]

(29)

From equations (28) and (29) the values of \(u\) and \(v\) can be determined in the first approximation for the point \(P_3\). In order to determine the value of \(w\) at \(P_3\), the following procedure can be used:

If \(s\) is the projection of the streamline in the meridian plane considered (fig. 5) and \(P_3\) is a point near \(P_1\) and \(P_2\),

\[
\frac{dw_3}{ds} = \frac{\partial w_3}{\partial y} \sin \beta + \frac{\partial w_3}{\partial x} \cos \beta
\]

\[
= \frac{\partial w_3}{\partial y} \frac{\sin \beta}{V} + \frac{\partial w_3}{\partial x} \frac{\cos \beta}{V}
\]

or from equation (12)

\[
\frac{\partial w_3}{\partial s} = \frac{\sin \beta V \Delta S_3}{y y}
\]

(30)

Now (fig. 5)

\[
\omega_{23} = \omega_{P_3} \left( \frac{\partial \omega}{\partial x} \right)_{P_3} \left( x_{P_3} - x_{P_1} \right) \left[ \frac{\cos \beta}{\cos (\phi + \beta)} \right]_{P_1}
\]

(31a)

\[
\omega_{3x} = \omega_{P_3} \left( \frac{\partial \omega}{\partial x} \right)_{P_3} \left( x_{P_3} - x_{P_2} \right) \left[ \frac{\cos \beta}{\cos (\phi - \beta)} \right]_{P_2}
\]

(31b)

and

\[
\frac{\partial \omega_3}{\partial s} = \frac{\omega_{23} - \omega_{3x}}{(x_{P_3} - x_{P_2}) \left[ \frac{\sin \beta}{\cos (\phi + \beta)} \right]_{P_1} + (x_{P_3} - x_{P_2}) \left[ \frac{\sin \beta}{\cos (\phi - \beta)} \right]_{P_2}}
\]

(32)

Therefore,

\[
\omega_{P_3} = \omega_{23} \left( \frac{\partial \omega_3}{\partial s} \right)_{P_3} \left( x_{P_3} - x_{P_2} \right) \left[ \frac{\sin \beta}{\cos (\phi + \beta)} \right]_{P_1}
\]

(33)

The values of \(u, v, w, \Delta S, u_1, v_1\), and \(\Delta S_1\) are known at the points \(P_1\) and \(P_2\); therefore, the values of \(w_1, v_1, w_1\), and \(\Delta S_1\) at the same points can be calculated from equations (5) and (11). (The values of \(u_1, v_1\), and \(\Delta S_1\) at those points are known from the determination of the flow for \(\alpha = 0\).) Therefore, from equations (30) to (33) the value of \(w_2\) at \(P_3\) can be determined.

After the velocity components \(u, v, w\) at \(P_3\) have been determined in the first approximation, a second approximation can be determined by assuming the average values between the corresponding values at the points \(P_1, P_3\) or \(P_1\) and \(P_2\) for all the coefficients. After the velocity components at a point \(P_3\) have been obtained, the velocity components at any other point having the same \(x\) and \(y\) coordinates as
but a different coordinate \( \theta \) can be calculated from equations (5).

For practical calculations, equations (28) can be transformed in the following form:

\[
\lambda_\alpha = \tan (\beta + \phi) \tag{34a}
\]

\[
\frac{dV}{V} - d\phi \tan \beta \left( \sin \frac{\phi}{y} + \frac{\partial w}{V \partial \theta} \right) \tan \beta = \frac{\sin^2 \beta}{\gamma R} \frac{d\omega}{dn} \frac{\sin \beta}{\cos (\phi + \beta)} \frac{dz}{\cos \Delta S_2} \tag{34b}
\]

\[
\lambda_\alpha = \tan (\phi - \beta) \tag{34c}
\]

\[
\frac{dV}{V} + d\phi \tan \beta \left( \sin \frac{\phi}{y} + \frac{\partial w}{V \partial \theta} \right) \tan \beta = \frac{\sin^2 \beta}{\gamma R} \frac{d\omega}{dn} \frac{\sin \beta}{\cos (\phi - \beta)} \frac{dz}{\cos \Delta S_2} \tag{34d}
\]

\[
1 \frac{dV}{\omega} = \frac{1}{V} \frac{V_2}{\omega} \frac{V_1}{\omega} \sin \phi \frac{\sin^2 \beta \Delta S_2}{y} \tag{34e}
\]

where

\[
\phi = \phi_1 + \alpha \phi_2 \cos \theta \tag{35}
\]

\[
\phi_2 = \frac{V_2}{V_1} \cos \phi_1 - \frac{u_2}{V_1} \sin \phi_1 \tag{36}
\]

and

\[
V = V_1 + \alpha V_2 \cos \theta \tag{37}
\]

where

\[
V = u_2 \cos \phi_1 + v_2 \sin \phi_1 \tag{38}
\]

At the surface of the body outside of the vortical layer the calculations are similar to the case of zero angle of attack because the entropy at the surface of the body is known in every meridian plane and the value of \( \theta \) is given. Equation (34e) gives the variation of \( \omega \) along the body outside of the layer; therefore, the value of \( \omega \) can be obtained directly from another point on the body in the same meridian plane.

At the surface of the shock the system of calculations is similar to the system for zero angle of attack. In figure 6 the point \( P_4 \) is at the intersection of the tangents to the first characteristic surface at \( P_1 \) and to the shock at \( P_2 \) in the meridian plane \( \theta = \text{Constant} \). The equations of the shock and equation (34b) must be verified at \( P_2 \), which is assumed as a point of the shock in the first approximation.

In the plane \( \theta = 0 \), \( w \) is zero and the values of \( V \), \( \Delta S \), and \( \phi \) behind the shock are functions only of the value of \( \Omega \); and for any value of \( \Omega \), the values of \( V \), \( \Delta S \), and \( \phi \) can be obtained from the equations of the shock

\[
\cos (\Omega - \alpha) = \frac{V}{V \omega} = \frac{V_1}{V_2} \frac{V_1}{V_2} \tag{39a}
\]

\[
\frac{1}{\tan (\phi - \alpha)} = \left[ \frac{\gamma + 1}{2} \frac{M_0^2 \sin^2 (\Omega - \alpha) - 1}{1} \right] \frac{1}{\tan (\Omega - \alpha)} \tag{39b}
\]

\[
\Delta S = \frac{R}{\gamma - 1} \log_\gamma \left( \frac{2}{\gamma + 1} \right)^\gamma \left[ \frac{M_0^2 \sin^2 (\Omega - \alpha)}{1} \right]^{\gamma - 1} \left( \frac{1}{M_0^2 \sin^2 (\Omega - \alpha) - 1} \right)^{\gamma - 1} \tag{39c}
\]

and

\[
\frac{V_2}{V_1} = \frac{1}{\gamma - 1} \frac{M_0^2}{\gamma - 1} \tag{39d}
\]

If the plane \( \theta = \pi \) is considered, the sign of \( \alpha \) in equations (39) must be reversed.

From equations (39) the values of \( V \) and \( \Delta S \) can be determined as a function of \( \phi \); then \( \frac{dV}{d\phi} \) and \( \frac{d\Delta S}{d\phi} \) as a function of \( \phi \) can be evaluated. Now, if \( \phi_{P_1} \) is the direction of the velocity at \( P_1 \), the velocity at \( P_2 \) will have the direction

\[
\phi_{P_2} = \phi_{P_1} + \Delta \phi
\]

Therefore, the velocity at \( P_2 \) must correspond to a deviation across the shock of \( \phi_{P_2} \) and can be expressed as

\[
V_{P_2} = V_{P_1} + \left( \frac{dV}{d\phi} \right)_{\phi_{P_1}} \Delta \phi
\]

where \( V_{P_1} \) is the velocity behind the shock corresponding to the direction \( \phi_{P_1} \). In a similar way,

\[
\Delta S_{P_2} = \Delta S_{P_1} + \left( \frac{d\Delta S}{d\phi} \right)_{\phi_{P_1}} \Delta \phi
\]

Therefore, equation (34b) at the point \( P_2 \) becomes

\[
\frac{V_{P_2}}{V_{P_1}} = 1 + \frac{\left( \frac{\partial V}{\partial \phi} \right)_{\phi_{P_1}}}{\frac{\Delta S}{\phi_{P_1}}} \frac{\Delta \phi - \tan \beta_{P_1} \Delta \phi -}{\frac{\left( \sin \phi + w_\alpha \cos \theta \right)}{y} \frac{\sin \beta \tan \phi}{\cos (\beta + \phi)} \frac{dz}{\cos \Delta S_{P_1}} + \left( \frac{\Delta S}{\phi_{P_1}} \frac{\Delta S}{\phi_{P_1}} \frac{\Delta \phi}{\gamma R} \right) \sin \frac{\beta_{P_1}}{\gamma R} = 0 \tag{40}
\]

In equation (40), \( \Delta \phi \) is the only unknown and, therefore, can be determined. From the value of \( \phi \) the value of \( \Omega_{P_2} \).
and the value of \( V' \) can be determined; a second approximation for the position of \( P_a \) and its value of the velocity can be calculated if the corresponding average values between \( P_a \) and \( P_1 \) are assumed for \( \phi, \beta, \) and all the coefficients of equation (40).

The value of \( \omega \) at \( P \) can be obtained from equation (23c) in which \( \eta \) is given by figure 6 as

\[
\eta = \frac{dN}{\gamma_a} \sin \Omega
\]

where \( \eta = \Omega - \sigma \) for \( \theta = 0 \) and \( \eta = \alpha - \Omega \) for \( \theta = \pi \). The value of \( \sigma \) corresponding to the point \( P_a \) on the shock for \( \alpha = 0 \) is given by the relation

\[
y P_a = \frac{y_{P_a}}{\sin \sigma - \sin \Omega}
\]

and \( y_{P_a} = f(\sigma_{P_a}) \) is the curve that represents the shock for \( \alpha = 0 \).

**PRACTICAL APPLICATION OF THE CHARACTERISTIC SYSTEM**

**GRAPHICAL NUMERICAL METHOD**

The analytical part of the characteristic system used for determining the flow field about a body of revolution at an angle of attack is similar to the system used for a body of revolution at zero angle of attack (reference 6), but the practical numerical application is slightly more involved. In equation (34c) the values of \( V' \) and \( \Delta S_1 \) must be known in order to determine the value of \( \omega_1 \) and must be determined from equations (37), (36), and (11), where the values of \( V_1 \) and \( \Delta S_1 \) are considered known in the entire flow field and given by the determination from the case of zero angle of attack. In the practical case, however, the values of \( V_1, \phi, \) and \( \Delta S_1 \) have been obtained with the characteristic system only in a finite number of points at the intersections of the characteristic net, and the characteristic net for the case of zero angle of attack is different from the net used for the case of a body with a small angle of attack. In order, therefore, to obtain the values of \( V_1 \) and \( \Delta S_1 \) at the intersections of the characteristic lines for the case with a given angle of attack, a lengthy interpolation of the values \( V_1 \) and \( \Delta S_1 \) would be necessary if the two characteristic nets for zero angle of attack and for a given angle of attack were constructed independently.

In order to reduce the numerical work to a minimum, the two following methods can be used, the first of which is practical when a graphical numerical calculation is performed, whereas the second can be more convenient when automatic computing machines are used.

In both cases the calculations start with the determination of the flow at an angle of attack around a cone when the body considered is a pointed-nose body of revolution or with the determination of the shock at the lip of the body if the body is an open-nose body of revolution. (The tangent to the shock at the lip can be determined with the two-dimensional theory.) The flow around a cone at an angle of attack has been determined and tabulated in reference 3; whereas the flow for zero angle of attack has been tabulated in reference 7. A different method for determining the flow around a circular cone at an angle of attack is given in the appendix. It can be assumed, therefore, that the flow along the first characteristic line of the first family at the end of the conical region in the plane \( \theta = \text{Constant} \) (for example, \( \theta = \pi \)) is known (fig. 7).

For the practical numerical calculations a value of the angle of attack must be selected. In order to obtain higher precision, it is convenient to select a relatively high value of the angle of attack because in this way the differences between \( V \) and \( V_1 \), and \( \Delta S_1 \) and \( \Delta S_1 \) are large and, therefore, can be determined with sufficient precision.

 Usually, when the determination of the flow field for the case of zero angle of attack is made with a graphical numerical process, in order to avoid numerical errors of computations, the value of the intensity and direction of the velocity are plotted as a function of the position along the characteristic lines for both families of characteristic lines. The velocity distribution and the entropy-variation distribution along the characteristic lines and along the surface of the body for the case of zero angle of attack can therefore be considered known. If the distribution is not given, the values of \( V_1 \) and \( \Delta S_1 \) must be determined as a function of \( x \) along each characteristic line of a given family (for example, of the second family) along the body.

Then the construction of the characteristic net for the selected angle of attack must start by drawing the first characteristic line \( P_2 P_3 P_4 \) over the design of the characteristic net for zero angle of attack (fig. 7).

From equations (34c), (34d), and (34e) the flow at \( P_1 \) can be determined. From \( P_1 \) and \( P_2 \) the point \( P_a \) can be obtained in the first approximation as the intersection of the tangents at \( P_2 \) and \( P_1 \) to the characteristic lines. By using equations (34b), (34d), and (29), \( V, \phi, \) and \( \Delta S \) can be obtained in \( P_a \).
as for the case of zero angle of attack (reference 6). From
the variations \( \frac{dV}{dx}, \frac{d\phi}{dx}, \) and \( \frac{d\Delta S}{dx} \) along the line \( P_1P_2 \) the values
of \( \dot{V}, \phi, \) and \( \Delta S \) at the point \( P_3 \) can be obtained, where \( P_3 \)
is obtained from the intersection of the characteristic line
\( P_1P_2 \) with a characteristic line of the second family in the net
for zero angle of attack. At the point \( P_3 \), \( V_1, \Delta S_1, \) and \( \phi_1 \) are
known and, therefore, \( \phi_3, V_3, \Delta S_3, \) and \( \omega_3 \) can be obtained.
From the values obtained from the first approximation a
second approximation can be obtained. From \( P_3 \) and \( P_4 \)
the point \( P_5 \) can be determined in a similar way, and the
flow at \( P_5 \) can be calculated. By proceeding in a similar
way, all the flow field can be analyzed.

**NUMERICAL METHOD**

The equation of motion (13) can be transformed by means
of equations (5) and (11) in a system of equations that
permits a numerical determination of the quantities \( V, \phi, \)
and \( \Delta S \). This system is numerically more involved;
however, the characteristic net determined for zero angle of
attack is used. For a small angle of attack,

\[
\frac{1}{a^2} = \frac{1}{a_1^2} \left[ 1 + \frac{1}{a_1^2} \left( u_1u_2 + v_1v_2 \right) \alpha \cos \theta \right]
\]

where

\[
\frac{1}{a_1^2} = \frac{1}{a_1^2} \left( 1 + A \alpha \cos \theta \right)
\]

Substituting equations (5) in equations (6) results in the
following expression if higher-order terms are neglected:

\[
\frac{\partial u_1}{\partial x} \left( 1 - \frac{u_1^2}{a_1^2} \right) + \frac{\partial v_1}{\partial y} \left( 1 - \frac{v_1^2}{a_1^2} \right) \frac{u_1v_1}{a_1^2} \left( \frac{\partial u_1}{\partial y} + \frac{\partial v_1}{\partial x} \right) + v_1 = \frac{\partial v_1}{\partial y} \left( \frac{v_1^2}{a_1^2} \right) + \frac{\partial v_1}{\partial x} \left( \frac{v_1^2}{a_1^2} \right) + \frac{v_1}{a_1^2} \left( \frac{\partial v_1}{\partial y} + \frac{\partial v_1}{\partial x} \right)
\]

\[
= -\alpha \cos \theta \left[ \frac{v_1}{a_1^2} \left( \frac{\partial v_1}{\partial y} + \frac{\partial v_1}{\partial x} \right) + v_1 \right]
\]

\[
= -\frac{\partial u_1}{\partial x} \left( 1 - \frac{u_1^2}{a_1^2} \right) - \frac{\partial v_1}{\partial y} \left( 1 - \frac{v_1^2}{a_1^2} \right) \frac{u_1v_1}{a_1^2} \left( \frac{\partial u_1}{\partial y} - \frac{\partial v_1}{\partial x} \right)
\]

Because the left-hand side of equation (42) must be zero
for the conditions at zero angle of attack,

\[
\frac{\partial u_1}{\partial x} \left( 1 - \frac{u_1^2}{a_1^2} \right) + \frac{\partial v_1}{\partial y} \left( 1 - \frac{v_1^2}{a_1^2} \right) + v_1 + w_3 v_1 = \frac{\partial u_1}{\partial y} + \frac{\partial v_1}{\partial x} + Q = 0
\]

where

\[
Q = -\frac{1}{2} \left( \frac{\partial u_1^2}{\partial x} + \frac{\partial v_1^2}{\partial y} \right) \frac{2u_1 + u_1 \Delta S}{a_1^2} - \frac{1}{2} \left( \frac{\partial v_1^2}{\partial y} + \frac{\partial v_1^2}{\partial x} \right) \frac{2v_1 + v_1 \Delta S}{a_1^2}
\]

\[
= \frac{\partial u_1}{\partial y} \left( \frac{u_1v_1 - u_1v_1}{a_1^2} \right) \frac{2u_1 + u_1 \Delta S}{a_1^2} - \frac{1}{2} \left( \frac{\partial v_1^2}{\partial y} + \frac{\partial v_1^2}{\partial x} \right) \frac{2v_1 + v_1 \Delta S}{a_1^2}
\]

or, from equations (9) and (36),

\[
Q = -V_1 \frac{\partial V_1}{\partial x} \frac{2u_1 + u_1 \Delta S}{a_1^2} = V_1 \frac{\partial V_1}{\partial y} \frac{2v_1 + v_1 \Delta S}{a_1^2} \frac{\phi_1 V_1}{\Delta S_1} \frac{\partial \Delta S_1}{\partial n_1} \gamma R \frac{\partial n_1}{\partial n_1}
\]

The value of all the coefficients at the points \( P_1 \) and \( P_2 \) in
equation (43) can be considered known because \( \frac{\partial V_1}{\partial x} \) and \( \frac{\partial V_1}{\partial y} \)
can be considered known from the calculations for the case
of zero angle of attack. Therefore, equation (43) can be
considered an equation in which the characteristic lines are
equal to the characteristic lines for zero angle of attack
because the coefficients of the partial derivatives \( \frac{\partial u_1}{\partial x}, \frac{\partial u_1}{\partial y} \)
\( \frac{\partial v_1}{\partial x}, \frac{\partial v_1}{\partial y} \)
are the same in both cases. Thus,

\[
\frac{dy}{dx} = \lambda_1 = \tan (\phi_1 + \beta_1)
\]

\[
\frac{dy}{dx} = \lambda_1 = \tan (\phi_1 - \beta_1)
\]

Equation (43) can be transformed by introducing the
entropy gradient \( \frac{\partial S_1}{\partial n_1} \), and the equation of motion along each
characteristic line can be obtained. From equations (9)
and (11) by means of equations (5) and (37), the following
relation can be obtained:

\[
\frac{\partial \Delta S_1}{\partial n_1} + \frac{\partial \Delta S_2}{\partial n_1} = \alpha \cos \theta
\]

\[
= -\left( \frac{\partial \Delta S_1}{\partial x} + \frac{\partial \Delta S_2}{\partial x} \alpha \cos \theta \right) \frac{v_1 + v_2 \alpha \cos \theta}{V_1 + V_2 \alpha \cos \theta} + \frac{\partial \Delta S_1}{\partial y} + \frac{\partial \Delta S_2}{\partial y} \alpha \cos \theta \right) \frac{u_1 + u_2 \alpha \cos \theta}{V_1 + V_2 \alpha \cos \theta}
\]

or, for small angles of attack,

\[
\frac{\partial \Delta S_1}{\partial n_1} + \frac{\partial \Delta S_2}{\partial n_1} \alpha \cos \theta + \left[ \frac{\partial \Delta S_1}{\partial x} \left( V_1 - v_1 V_2 \right) \right] \frac{\partial \Delta S_1}{\partial y} \left( V_1 - v_1 V_2 \right)
\]

\[
\frac{\partial \Delta S_1}{\partial y} \left( V_1 - v_1 V_2 \right) \alpha \cos \theta
\]

\[
\frac{\partial \Delta S_1}{\partial y} \left( V_1 - v_1 V_2 \right) \alpha \cos \theta
\]
From equations (36) and (38)
\[ u_2 = V_1 \cos \phi_1 - \phi_2 V_1 \sin \phi_1 \]  
(48a)
and
\[ v_1 = V_1 \sin \phi_1 + \phi_2 V_1 \cos \phi_1 \]  
(48b)
Therefore,
\[ S = \frac{\partial S_1}{\partial z} (v_1 V_1 - u_2 V_2) + \frac{\partial S_2}{\partial y} (u_2 V_1 - u_1 V_1) \]
\[ = -\phi_2 V_1^2 \left( \frac{\partial S_1}{\partial z} (V_1) + \frac{\partial S_2}{\partial y} (V_1) \right) \]
Because the term in parentheses on the right-hand side of this equation represents the variation of entropy along the streamline, which is zero, equation (47) becomes
\[ \frac{\partial S}{\partial n} = \frac{\partial S_1}{\partial n_1} + \frac{\partial S_2}{\partial n_2} \alpha \cos \theta \]  
(49)
Then, from equations (9), (41), and (49)
\[ \frac{\partial v_2}{\partial x} - \frac{\partial u_2}{\partial y} = \frac{a_1^2}{\gamma R V_1} \frac{\partial S_2}{\partial n_1} \left( V_1 + A \right) \frac{a_1^2}{\gamma R V_1} \frac{\partial S_1}{\partial n_1} \]  
(50)
The equations of motion along the characteristic lines defined by equations (46) can be obtained by means of transformations similar to those of equations (27) and are
\[ du_2 + \lambda_{1a} dv_2 + D_1 dx = 0 \]  
(51)
\[ \lambda_{1a} = \frac{dy}{dx} = \tan (\phi_1 + \beta_1) \]  
(52)
\[ du_2 + \lambda_{1a} dv_2 + D_2 dx = 0 \]  
(53)
\[ \lambda_{1a} = \frac{dy}{dx} = \tan (\phi_1 - \beta_1) \]  
(54)
where
\[ D_1 = \left( \frac{w_2}{y} + \frac{v_2}{y} + Q \right) \frac{a_1^2}{a_1^2 - u_1^2} + \left( \frac{w_1}{y} + \frac{v_1}{y} + \lambda_{1a} \right) \frac{V_1}{\gamma R} \sin^2 \beta_1 \left[ \frac{\partial S_2}{\partial n_1} - \frac{V_2}{V_1} \left( 1 + \frac{\gamma - 1}{\sin^2 \beta_1} \right) \frac{\partial S_1}{\partial n_1} \right] \]  
(55a)
\[ D_2 = \left( \frac{w_2}{y} + \frac{v_2}{y} + Q \right) \frac{a_1^2}{a_1^2 - u_1^2} + \left( \frac{w_1}{y} + \frac{v_1}{y} + \lambda_{1a} \right) \frac{V_1}{\gamma R} \sin^2 \beta_1 \left[ \frac{\partial S_2}{\partial n_1} - \frac{V_2}{V_1} \left( 1 + \frac{\gamma - 1}{\sin^2 \beta_1} \right) \frac{\partial S_1}{\partial n_1} \right] \]  
(55b)
In equations (51) and (53) the coefficients \( D_1 \) and \( D_2 \) contain the derivatives \( \frac{\partial V_1}{\partial x} \) and \( \frac{\partial V_1}{\partial y} \) that must be obtained from the analysis of the case with zero angle of attack. Now, for every point \( P \) the variation of \( V_1 \) along the characteristic line of the first family for the case of zero angle of attack is
\[ \left( \frac{dV_1}{dx} \right)_{\lambda_{1a}} = \frac{\partial V_1}{\partial x} + \lambda_{1a} \frac{\partial V_1}{\partial y} \]  
(56a)
whereas along the characteristic line of the second family
\[ \left( \frac{dV_1}{dx} \right)_{\lambda_{1b}} = \frac{\partial V_1}{\partial x} + \lambda_{1b} \frac{\partial V_1}{\partial y} \]  
(56b)
At every point \( P \) given by the intersection of two characteristic lines \( \lambda_{1a} \) and \( \lambda_{1b} \) in the characteristic net, the values \( \left( \frac{dV_1}{dx} \right)_{\lambda_{1a}} \) and \( \left( \frac{dV_1}{dx} \right)_{\lambda_{1b}} \) are known, having been obtained from the evaluation of the following equations (reference 5):
\[ \frac{dy}{dx} = \lambda_{1a} = \tan (\phi_1 + \beta_1) \]  
(57a)
\[ \frac{dy}{dx} = \lambda_{1b} = \tan (\phi_1 - \beta_1) \]  
(57b)
\[ \frac{1}{V_1} \left( \frac{dV_1}{dx} \right)_{\lambda_{1a}} - \tan \beta_1 \left( \frac{d\phi_1}{dx} \right) \frac{\sin \phi_1 \sin \beta_1 \tan \beta_1}{\cos (\phi_1 + \beta_1)} \frac{1}{y} + \frac{\sin^2 \beta_1}{\cos (\phi_1 + \beta_1)} = 0 \]  
(57c)
\[ \frac{dy}{dx} = \lambda_{1b} = \tan (\phi_1 - \beta_1) \]  
(57d)
\[ \frac{1}{V_1} \left( \frac{dV_1}{dx} \right)_{\lambda_{1b}} + \tan \beta_1 \left( \frac{d\phi_1}{dx} \right) \frac{\sin \phi_1 \sin \beta_1 \tan \beta_1}{\cos (\phi_1 - \beta_1)} \frac{1}{y} - \frac{\sin \beta_1}{\cos (\phi_1 - \beta_1)} = 0 \]  
(57d)
Therefore, the values
\[ \frac{\partial V_1}{\partial x} = \frac{\lambda_{1a} - \lambda_{1b}}{\lambda_{1a} - \lambda_{1b}} \left( \frac{dV_1}{dx} \right)_{\lambda_{1a}} - \frac{\lambda_{1b} - \lambda_{1a}}{\lambda_{1a} - \lambda_{1b}} \left( \frac{dV_1}{dx} \right)_{\lambda_{1b}} \]  
(58a)
and
\[ \frac{\partial V_1}{\partial y} = \frac{1}{\lambda_{1b} - \lambda_{1a}} \left[ \left( \frac{dV_1}{dx} \right)_{\lambda_{1b}} - \left( \frac{dV_1}{dx} \right)_{\lambda_{1a}} \right] \]  
(58b)
can be calculated directly for every point of intersection of the characteristic line (equations (57a) and (57c)).
After substituting the expressions of equations (48) and (58) in equations (51) and (53) after some simplifications and trigonometric transformations, the following equations can be obtained:
\[ \lambda_{1a} = \frac{dy}{dx} = \tan (\phi_1 + \beta_1) \]  
(59a)
The coefficients \( A_1 \) and \( A_2 \) and the value of \( \frac{dS}{d\gamma} \) have been determined for the flow at zero angle of attack and

\[
\begin{align*}
\frac{dV_2}{V_1} \tan \beta_1 d\phi + & \left[ \frac{\sin^2 \beta_1}{\cos (\phi_1 + \beta_1)} \frac{1}{\gamma R} \frac{dS_1}{dn_1} + \phi_2 A_2 \right] dx = 0 \quad (59b) \\
\lambda_{12} = & \frac{dy}{dx} = \tan (\phi_1 - \beta_1) \quad (59c) \\
\frac{dV_2}{V_1} \tan \beta_1 d\phi - & \left[ \frac{\sin^2 \beta_1}{\cos (\phi_1 - \beta_1)} \frac{1}{\gamma R} \frac{dS_1}{dn_1} + \phi_2 A_2 \right] \frac{V_2}{V_1} P_2 + \\
& \frac{w_2}{V_1} \frac{1}{\gamma R} \frac{dS_1}{dn_1} \sin \beta_1 \right] dx = 0 \quad (59d)
\end{align*}
\]

where

\[
\begin{align*}
A_1 = & \frac{1}{\cos \beta_1 \cos (\phi_1 + \beta_1)} \left[ \frac{\sin \beta_1}{y} \sin (\phi_1 - \beta_1) + \frac{\sin^3 \beta_1}{\gamma R} \frac{dS_1}{dn_1} \right] \\
& \frac{1}{V_1} \left( \frac{dV_1}{dx} \right) \lambda_{12} \sin \beta_1 \\
A_2 = & \frac{1}{\cos \beta_1 \cos (\phi_1 - \beta_1)} \left[ \frac{\sin \beta_1}{y} \sin (\phi_1 + \beta_1) - \frac{\sin^3 \beta_1}{\gamma R} \frac{dS_1}{dn_1} \right] \\
& \frac{1}{V_1} \left( \frac{dV_1}{dx} \right) \lambda_{12} \cos \beta_1 \\
P_1 = & \frac{1}{V_1} \left( \frac{dV_1}{dx} \right) \lambda_{12} \left( T \frac{\cos^2 \beta_1 - 1}{\cos \beta_1} \right) + T \left[ \frac{2 \sin^2 \beta_1}{\gamma R \cos (\phi_1 + \beta_1)} \frac{dS_1}{dn_1} \right] \\
& \frac{1}{V_1} \left( \frac{dV_1}{dx} \right) \lambda_{12} \cos \beta_1 \cos (\phi_1 - \beta_1) \\
P_2 = & \frac{1}{V_1} \left( \frac{dV_1}{dx} \right) \lambda_{12} \left( T \frac{\cos^2 \beta_1 - 1}{\cos \beta_1} \right) + T \left[ \frac{2 \sin^2 \beta_1}{\gamma R \cos (\phi_1 - \beta_1)} \frac{dS_1}{dn_1} \right] \\
& \frac{1}{V_1} \left( \frac{dV_1}{dx} \right) \lambda_{12} \cos \beta_1 \cos (\phi_1 + \beta_1) \\
T = & \frac{\gamma - 1}{2 \sin^2 \beta_1} \\
\end{align*}
\]

The practical use of equations (59) is identical to the use of the corresponding equations (57) for the case of zero angle of attack. (See reference 6.)

CONCLUDING REMARKS

The method of characteristics has been applied to bodies of revolution at a small angle of attack. Only the first-order effects of the angle of attack have been considered. The system developed takes into account the effects of the entropy variations on the flow phenomena and determines a flow that exactly satisfies the boundary conditions within the limits of the simplifications assumed.

The application of the method to practical problems has been discussed and two systems are given. The first method is numerical and analytical and requires less numerical computation but requires the construction of another characteristic net; whereas the second method is only numerical and uses the characteristic net and some of the numerical computations made for the calculations for zero angle of attack.

APPENDIX

DETERMINATION OF FLOW PROPERTIES AROUND A CIRCULAR CONE AT A SMALL ANGLE OF ATTACK

Assume a polar coordinate system \( r, \psi, \theta \). Call \( v_r \), the velocity in radial direction, \( v_\theta \), the velocity in normal direction to \( r \) in the meridian plane \( \theta = \) Constant, and \( w \) the component normal to the meridian plane (fig. 8); that is,

\[
\begin{align*}
& v_r = \frac{dr}{dt} \\
& v_\theta = \frac{r}{t} \frac{d\psi}{dt} \\
& w = \frac{r}{t} \frac{d\theta}{dt} \sin \psi
\end{align*}
\]

If the phenomenon is conical,

\[
\begin{align*}
\frac{\partial v_r}{\partial r} &= 0 \\
\frac{\partial v_\theta}{\partial r} &= 0 \\
\frac{\partial w}{\partial r} &= 0
\end{align*}
\]

and

\[
\begin{align*}
\frac{\partial p}{\partial \theta} &= 0 \\
\frac{\partial \rho}{\partial \theta} &= 0
\end{align*}
\]

Therefore, Euler's equations are

\[
\begin{align*}
\frac{v_r}{r} \frac{\partial v_r}{\partial \psi} + \frac{w}{r} \frac{\partial v_\theta}{\partial \psi} + \frac{v_r^2 + w^2}{r} &= 0 \\
\frac{v_\theta}{r} \frac{\partial v_\theta}{\partial \psi} + \frac{w}{r} \frac{\partial v_\theta}{\partial \psi} + \frac{v_\theta^2 + w^2}{r} &= 0 \\
\frac{v_r}{r} \frac{\partial v_r}{\partial \theta} + \frac{w}{r} \frac{\partial v_\theta}{\partial \theta} + \frac{v_r}{r} \frac{\partial v_\theta}{\partial \theta} + \frac{v_\theta}{r} \frac{\partial v_r}{\partial \theta} + \frac{w}{r} \frac{\partial v_\theta}{\partial \theta} + v_r v_\theta \cot \psi &= 0
\end{align*}
\]

The continuity equation is

\[
\begin{align*}
\frac{\rho}{r} \frac{\partial v_r}{\partial \psi} + \rho \frac{\partial v_\theta}{\partial \psi} \sin \psi + v_r \frac{\partial v_\theta}{\partial \theta} + \frac{v_\theta}{r} \frac{\partial v_r}{\partial \theta} + \frac{w}{r} \frac{\partial v_\theta}{\partial \theta} &= 0
\end{align*}
\]

and the energy equation is

\[
\begin{align*}
\frac{\gamma}{\gamma - 1} \left( \frac{1}{\rho} \frac{\partial p}{\partial \psi} - \frac{p}{\rho^2} \frac{\partial \rho}{\partial \psi} \right) &= -\left( v_r \frac{\partial v_r}{\partial \psi} + v_\theta \frac{\partial v_\theta}{\partial \psi} + w \frac{\partial w}{\partial \psi} \right) \\
\frac{\gamma}{\gamma - 1} \left( \frac{1}{r} \frac{\partial p}{\partial \theta} - \frac{p}{r^2} \frac{\partial \rho}{\partial \theta} \right) &= -\left( v_r \frac{\partial v_r}{\partial \theta} + v_\theta \frac{\partial v_\theta}{\partial \theta} + w \frac{\partial w}{\partial \theta} \right)
\end{align*}
\]

Combining equations (62) to (64) results in

\[
\begin{align*}
& v_\theta \left( 2 - \frac{v_\theta^2 + w^2}{a^2} \right) + v_\theta \cot \psi + \frac{\partial v_\theta}{\partial \psi} \left( 1 - \frac{v_\theta^2}{a^2} \right) + \frac{\partial w}{\partial \psi} \\
& \sin \psi \frac{\partial v_\theta}{\partial \psi} \left( 1 - \frac{v_\theta^2}{a^2} \right) - 2 \frac{w v_\theta}{a^2} \frac{\partial v_\theta}{\partial \psi} + \frac{\partial v_\theta}{\partial \theta} + \frac{\partial v_\theta}{\partial \theta} = 0
\end{align*}
\]

(65)

For small angles of attack the velocity components can be expressed in the form (references 1 and 3)

\[
\begin{align*}
v_r = v_{r1} + \alpha v_{r2} \cos \theta \\
v_\theta = v_{\theta1} + \alpha v_{\theta2} \cos \theta \\
w = \alpha w_\theta \sin \theta
\end{align*}
\]

when the second- and higher-order terms of the angle of attack have been neglected. Equation (65) at small angles of attack becomes

\[
\begin{align*}
& v_\theta \left( 2 - \frac{v_\theta^2}{a^2} \right) + v_\theta \cot \psi + \frac{\partial v_\theta}{\partial \psi} \left( 1 - \frac{v_\theta^2}{a^2} \right) + \frac{\partial w}{\partial \psi} = 0
\end{align*}
\]

(67)
The shock is a circular conical shock having its axis inclined at an angle $\eta$ with the axis of the cone. The quantities with subscript 1 are the quantities corresponding to the case of zero angle of attack. (Indeed, the cone is a particular body of revolution and, therefore, the considerations made for the case of bodies of revolution are still valid.) From equations (62a), (62b), and (64b), there results at small angles of attack

$$\frac{1}{\rho} \frac{\partial p}{\partial \psi} - \gamma \frac{\partial \rho}{\partial \psi} = 0$$

In the meridian plane $\theta=$Constant, therefore, the transformation behind the shock is isentropic for small angles of attack. If $-\alpha \Delta S_2 \sin \theta$ is the variation of entropy in a direction normal to the meridian plane $\theta=$Constant (reference 5),

$$\frac{\partial S}{\sin \psi \partial \theta} = -\alpha \Delta S_2 \sin \theta$$

where $\Delta S_2$ is constant and independent of $\psi$ outside of the vortical layer. From equations (62c) and (64a)

$$-\frac{a^2}{\gamma R_s} \Delta S_a = v_x \frac{\partial v_x}{\partial \psi} \sin \psi + w_z (v_r \sin \psi + v_a \cos \psi) + v_r v_x + v_a v_z$$

(68)

If the variation of entropy is small and the term $\Delta S_a$ can be neglected, equation (68) becomes

$$w_z \sin \psi = -v_r$$

(69)

Equation (67) can be written in the following form:

$$\left( v_r + \frac{\partial v_x}{\partial \psi} \right) \left( 1 - \frac{v_x^2}{a^2} \right) = -v_r - v_a \cot \psi - \frac{\alpha w_z \cos \theta}{\sin \psi}$$

(70)

By use of equation (67) and by considering the conditions for zero angle of attack, equation (70) becomes

$$\left( \frac{v_x + \frac{\partial v_x}{\partial \psi}}{v_a} \right) \left( 1 - \frac{v_x^2}{a^2} \right) = -v_x \left[ \cot \psi + \left( \frac{v_x + \frac{\partial v_x}{\partial \psi} \frac{v_x + v_a \cot \psi}{1 - \frac{v_x^2}{a^2}} - \frac{w_z}{\sin \psi} \right) \right]$$

(71)

Equations (68), (70), and (71) permit the determination of the flow around the cone at an angle of attack by means of a step-by-step calculation when the calculation for $\alpha=0$ has been performed. Consider the hodograph plane $uv$, and consider the variation of velocity components $v_r$ and $v_a$ in a meridian plane $\theta=$Constant (fig. 9). Assume that for a given value of $\psi_a$ and $\theta_a$ the velocity components $v_r$, $v_a$, and $w$ are known. Point $P_0$ of the hodograph diagram represents the velocity vector $OP_a$ corresponding to the velocity at every point of the space of coordinate $\psi_a$ in the plane $\theta_a=$Constant; whereas $Q_0P_a$ represents the values of $(v_0, \psi_a)$ and $Q_0P_a$ represents the values of $(v_0, \psi_a)$. Now, the radius of curvature $R_s$ of the hodograph diagram is along the line $Q_0P_a$ and has a value given by (reference 1)

$$R_s = \left( v_r + \frac{\partial v_x}{\partial \psi} \right)$$

and, therefore, can be determined from equation (70). At $P_0$ the values of $v_r$ and $v_a$ are known from the calculation for $\alpha=0$; therefore, $\alpha w_z$ and $\alpha w_a$ can be determined from equations (66). Equation (71) can be used in place of equation (70) in the following way: The vectors $OQ_a$ and $Q_0P_a$ represent the values of $v_x$ and $v_a$ at $P_a$; the vector $OP_a$ in the hodograph diagram gives the values of $V_x$; therefore,

$$R_s = \left( v_x + \frac{\partial v_x}{\partial \psi} \right)$$

can be obtained from equation (71).

Now at any point $P_a$ the radius $R_s$, given from equation (70), or the radius $R_s$, given from equation (71), is known; therefore, from the quantities at $P_a$ of coordinate $\psi_a = \psi_a + \Delta \psi$ can be obtained by constructing a circle of center $C_a$ (where $C_aP_a = R_s$ or $R_{sa}$) through the point...
P, until the point P, along the line C, which is a straight line from C, is inclined by $\psi_0 + \Delta \psi$ with the $u$-axis. Therefore,

$$(v_3)_{\psi + \Delta \psi} = (v_3)_{\psi} \cos \Delta \xi + (R-v_1)_{\psi} \sin \Delta \xi$$

$$(v_1)_{\psi + \Delta \psi} = (v_1)_{\psi} \sin \Delta \xi - (R-v_1)_{\psi} \cos \Delta \xi + R_{\psi}$$

Inasmuch as the values of $v_1$ and $v_3$ at P, have been obtained, the values of $v_{n_3}$ and $v_{n_2}$ can be determined by differences from the values for $\alpha=0$ with the use of equations (66). (If equation (71) is used, the values of $v_{n_3}$ and $v_{n_2}$ are obtained directly.) With equation (68) the value of $\frac{\partial w_2}{\partial \psi}$ can be calculated at P, and the value of $w_2$ at P, can be obtained. Indeed, $\Delta S_2$ is constant and has been determined from the conditions at the shock. In a similar way, all the hodograph diagram can be constructed. If necessary, for every point P, a second approximation can be determined.

The calculation of all the flow field must start at the shock. For the calculations it is convenient to choose a coordinate system having the axis of the conical shock as the axis of polar coordinates. In this case, the velocity components $v_\alpha$, $v_\eta$, and $w$ behind the shock can still be expressed in the form of equations (66). Indeed, from equations (15) and (19),

$$v_\alpha = \left[ v_{n_3} + \alpha \cos \theta \left( v_{n_2} + \frac{\eta \partial v_{n_2}}{\partial \psi} \right) \right]_0$$

$$v_\eta = v_{n_2} + (\alpha-\eta) v_{n_3} \cos \theta$$ (72a)

$$v_\psi = \left[ v_{n_3} + \alpha \cos \theta \left( v_{n_2} + \frac{\eta \partial v_{n_2}}{\partial \psi} \right) \right]_0$$

$$= v_{n_2} + (\alpha-\eta) v_{n_3} \cos \theta$$ (72b)

$$w_\psi = \alpha \sin \theta \left( w_{n_3} + \frac{1}{\sin \psi} \eta v_{n_3} \right)$$

$$= (\alpha-\eta) w_{n_3} \sin \theta$$ (72c)

where $v_{n_3}$, $v_{n_2}$, and $w_{n}$ are the components referred to the axis of the conical shock, whereas the components $v_\alpha$, $v_\eta$, and $w_{n}$ are referred to the axis of the body. Indeed, $\eta/\alpha$ is constant.

The calculations start at the shock. After determining the flow field for zero angle of attack, the angle of the conical shock $\psi_0$ is known and the velocity components $v_\alpha$, $v_\eta$, and $v_\psi$ with respect to the axis of the shock for every value of $\eta$ are also known. In order to determine the flow for the case of a small angle of attack, the direction of the undisturbed velocity must be rotated at a small angle $\alpha-\eta$ with respect to the axis of the shock (fig. 10). The value assumed for $\alpha-\eta$ fixes the value of $\alpha$ for which the calculations are performed. (This value of $\alpha$ is not yet known but is obtained as a result of the calculation.)

For a unitary value of $\alpha-\eta$, the component $v_{n_3}$ behind the shock can be determined from equation (14b) ($v_{n_3}=v_{n_3}'$) and the component $w_{n_3}$ from equation (14c) ($w_{n_3}'=w_{n_3}$); whereas $v_{n_2}$ can be determined from equation (21a) ($v_{n_2}'=-v_{n_2}'$) and $v_{n_2}'$ is given by equation (14a). The value of entropy $(\alpha-\eta)\Delta S_2 \cos \theta$ can also be determined from the equation of the shock, for example, from the difference between $\Delta S$ and $\Delta S_2$. When $v_{n_2}$, $v_{n_3}$, $w_{n_3}$, and $\Delta S_2$ are known behind the shock, all the flow field can be obtained by means of equations (68) and (70) or (71). The hodograph diagram can be constructed, for example, in the plane $\theta=\pi$.

The axis $u$ has been chosen in the direction of the undisturbed velocity for zero angle of attack that corresponds to the axis of the shock for $\alpha=0$. For $\alpha$ the undisturbed velocity has been rotated at $\alpha-\eta$ with respect to the $u$-axis (fig. 10); therefore, the axis of the shock has not been changed. The velocity OP, behind the shock of figure 9 must be decomposed into (1) a component $PQ_{\psi_0}$ inclined at $\psi_0$, and corresponding to $v_\psi$ if equation (70) is used or to $v_{n_3}$ if equation (71) is used and (2) a component $OQ_{\psi_0}$ corresponding to $v_{n_3}$ or $v_{n_3}'$.

In this way, the values of $v_{n_3}$ and $v_{n_3}'$ that must be used in equations (68), (70), and (71) are the values obtained from the calculations for zero angle of attack at the same value of $\psi$ (that is, $\psi=\psi_0$ for $P_0$). Because the calculations start at the shock, the construction of the hodograph diagram must be performed in the direction of decreasing values of $\psi$. 

![Figure 10](image-url)
At the surface of the body for \( \theta = \pi \), the component \( v_n \) must be zero; therefore, when the radius of the hodograph diagram passes at the origin of coordinates \( u \) and \( v \), the corresponding value of \( \psi \) is equal to \( \phi_0 + \eta \) where \( \phi_0 \) is the angle of the cone (fig. 10). Because \( \phi_0 \) is known, the value of \( \eta \) and, therefore, of \( \alpha \) can be determined.

The components \( v_r \) and \( v_\theta \) in the plane \( \theta = 0 \) or \( \theta = \pi \) do not change when, for the axis of reference, the axis of the body is assumed; but the corresponding value of \( \psi \) is increased at \( \eta \) (fig. 10). The value of \( \omega_0 \) changes; the value of \( \omega_0' \) can be determined from the value of \( \omega_0 \) by means of equation (72c).

For practical calculations it is convenient to use nondimensional coefficients obtained by dividing all the velocity components by the limiting velocity \( V_L \). The expression \( a/V_L \) can be obtained from equation (39d).

For small values of \( \alpha \), the values of \( v_r, v_\theta, \omega_0, \nabla \alpha \) are independent of \( \alpha \) and, therefore, the flow for every other value of \( \alpha \) can be obtained from this determination. The calculations can be graphical or analytical.
