• Polarimetric Calibration
Introduction

Basic SAR measurement parameters are:

- Radar backscattering
- Target position
- Target speed
- Polarisation

SAR calibration facilitates *quantitative* measurements needed to derive geophysical parameters of the area under observation from basic SAR measurements (e.g. soil moisture, biomass, ocean wave energy, ocean currents, ice type, ice flow,.....)
Radiometric Calibration

Radiometric calibration is relating the SAR output in terms of digital number to $\sigma^0$.

- Design for stability
- Sensor calibration
  - pre-flight characterisation
  - internal calibration
  - external calibration
- Data calibration

Internal Calibration

The objective of internal calibration is monitoring system parameter changes with time, such as

- Output power
- Receiver gain
- Linear distortion (amplitude & phase)
- Non-linear distortion (amplitude & phase)
- Noise level
- Level of spurious signals

Internal calibration methods include

- Calibration using transmit pulse sample (ERS-1 method)
- Reference signals: noise, cw
- Transmit power measurements

External Calibration

The objective of external calibration is to measure and monitor system components outside the internal calibration loop.

External calibration uses made-made or natural targets.

External calibration can be used to determine the radar image calibration factor either in combination or without reference to internal calibration.

Calibration of other areas

The application of the calibration factor to other areas requires knowledge of geometry (range & antenna angle) and stability over time.

High resolution information about the antenna diagram can be obtained from imagery of extended uniform targets such as the tropical forest or ice shelves.

No absolute information is required for these 'targets of opportunity'. Stability over time and a smooth dependence of $\sigma^0$ on incidence angle is necessary.
Data calibration

Data calibration include the following steps

- Correct raw data for a number of system parameters
  - Linear distortion (amplitude & phase)
  - Non-linear distortion
  - Detector imperfections (DC-biases, amplitude & phase imbalance)
  - time variations as measured by internal calibration
  - noise bias
- Application of calibration factor to the entire image, taking into account geometry and antenna angle.
Geometric calibration

Geometric calibration can be achieved following the same principles as for radiometric calibration.

- Design for stability
- Characterise SAR system in terms of delay, phase error and frequency offset
- Calibrate using point target with accurately known position

Geometric image calibration is carried out in the data calibration stage by correction for known system biases and applying geometry information (platform position & attitude and terrain models).
Phase calibration

During the formation of an intensity image the phase information in the radar data is lost. For applications in interferometry and polarimetry complex images are formed which provide two data points per pixel, amplitude & phase or real & imaginary parts of the complex signal.

Careful and elaborate phase characterisation of both the SAR sensor and the SAR processor are required. Time stability is critical for the above applications.
Polarimetric calibration

Polarimetric calibration can be treated essentially as a multi-channel extension of the methods discussed above. Polarimetric SAR differ from single channel SAR in the following ways.

- There are two orthogonal transmit channels to consider and four receive channels.
- Radiometric calibration can be separated into absolute calibration and relative between channel calibration
- Geometric calibration can be separated into absolute calibration and relative between channel calibration
- Phase calibration between channels is essential
- Crosstalk has to be taken into account
