Neural network algorithms have impressively demonstrated the capability of modelling spatial information. On the other hand, the application of parallel distributed models to processing of temporal data has been severely restricted. The invention introduces a novel technique which adds the dimension of time to the well known back-propagation neural network algorithm. In the space-time neural network disclosed herein, the synaptic weights between two artificial neurons (processing elements) are replaced with an adaptable-adjustable filter. Instead of a single synaptic weight, the invention provides a plurality of weights representing not only association, but also temporal dependencies. In this case, the synaptic weights are the coefficients to the adaptable digital filters.

NEURAL NETWORK FOR PROCESSING BOTH SPATIAL AND TEMPORAL DATA WITH TIME BASED BACK-PROPAGATION

ORIGIN OF THE INVENTION

The invention described herein was made by employees of the United States Government and may be manufactured and used by or for the Government of the United States of America for governmental purposes without payment of any royalties thereon or therefor.

BACKGROUND OF THE INVENTION

The present invention relates to a neural network for processing both spacial and temporal data (hereinafter "spatial-time neural network") and to an artificial neuron, or so-called "processing element", for use in such a space-time neural network.

More particularly, the invention relates to a space-time neural network, and a processing element therefor, which receives a temporal sequence of inputs \( X(n), X(n-1), X(n-2), \ldots \), where each input \( X(k) \) is comprised of \( N \) components \( x_1(n), x_2(n), \ldots, x_k(n), \ldots, x_N(n) \), and which maps such input representations into a single, plural-component output representation. The network may be a single layer network or it may comprise multiple layers of processing elements.

HISTORICAL PERSPECTIVE

Throughout history, the meaning of time has plagued the minds of mankind. The wise Greek philosophers, Socrates, Plato and Aristotle, pondered deeply about the influence of time had on human knowledge. The English poet, Ben Johnson, wrote

"...time adorns the face of things as it doth..."

and also maintains the cell's health. The information processed by the neuron is distributed by its axon to other interconnected neurons by the propagation of a spike or action potential. Along each dendrite are thousands of protrusions where neurons exchange information through a region known as the "synapse". The synaptic cleft releases chemicals called "neurotransmitters".

Connectionist architectures have impressively demonstrated several models of capturing temporal and spatial knowledge. To accomplish this, the most popular solution has been to distribute a temporal sequence by forcing it into a spatial representation. This method has worked well in some instances. See, e.g., J. A. Villarreal and P. Baffes, "Sunspot Prediction Using Neural Networks", SOAR '89—Third Annual Workshop on Automation and Robotics. 1987. But there are insurmountable problems with this approach and it has ultimately proven inadequate as a general technique.

Review of Neural Networks

A neural network is comprised of numerous, independent, highly interconnected artificial neurons, hereinafter called "processing elements", which simulate the functions of biological neurons. For so-called "back-propagation networks", each element can be characterized as having some input connections from other processing elements and some output connections to other elements. The basic operation of a processing element is to compute its activation value based upon its inputs and to send that value to its output. FIG. 2 is a schematic diagram of such a processing element. Note that this element has a input connections coming from \( j \) input processing elements. Each connection has an associated value called a "weight". The output of this processing element is a non-linear transform of its summed, continuous-valued inputs by the so-called "sigmoid transformation", as discussed in D. E. Rumelhart et al. "Learning Internal Representations by Error Propagation", in D. E. Rumelhart & J. L. McClelland (Eds.), Parallel Distributed Processing: Explorations in the Microstructure of Cognition (Vol. 1) (pp. 318-362) MIT Press, 1986, Cambridge, Mass.
When groups of such processing elements are arranged in sequential layers, each layer interconnected with the subsequent layer, the result is a wave of activations propagated from the input processing elements, which have no incoming connections, to the output processing elements. The layers of elements between the inputs and outputs take on intermediate values which perform a mapping from the input representation to the output representation. It is from these intermediate or "hidden" elements that the back-propagation network draws its generalization capability. By forming transformations through such intermediate layers, a back-propagation network can arbitrarily categorize the features of its inputs.

\[ E_i = \sum w_p p_i \]
\[ p_i = \frac{P(E)}{1 + e^{-E_i}} \]

The Weights Of A Back-propagation Network

The heart of the back-propagation algorithm lies in how the values of its interconnections, or weights, are updated. Initially, the weights in the network are set to some small random number to represent no association between processing elements. Upon being given a set of patterns representing pairs of input/output associations, the network enters what is called a "training phase".

During training, the weights are adjusted according to a learning algorithm. As described by Rumelhart et al. The training phase is modeled after a behavioristic approach which operates through reinforcement by negative feedback. That is, the network is given an input from some input/output pattern for which it generates an output by propagation. Any discrepancies found when comparing the network's output to the desired output constitute mistakes which are then used to alter the network characteristics. According to the Rumelhart et al. technique, every weight in the network is adjusted to minimize the total mean square errors between the response of the network, \( P_\text{network} \), and the desired outputs, \( P_\text{desired} \), to a given input pattern. First, the error signal, \( \xi_n \), is determined for the output layer, \( n \):

\[ \xi_n^{(n)} = (1 - p)^{n}P(E^{(n)}) \]  

(3)

The indices \( n \) and \( i \) represent the pattern number and the index to a node respectively. The weights are adjusted according to:

\[ \Delta w_j^{(n+1)} = \Delta w_j^{(n)} + \eta \xi_n^{(n+1)} p_j^{(n)} \]

(4)

where \( \Delta w_j^{(n)} \) is the error gradient of the weight from the \( j \)-th processing element in layer \( n \) to the \( i \)-th unit in the subsequent layer (\( n+1 \)). The parameter \( \alpha \) performs a damping effect through the multi-dimensional error space by relying on the most recent weight adjustment to determine the present adjustment. The overall effect of this weight adjustment is to perform a gradient descent in the error space; however, note that true gradient descent implies infinitesimally small increments. Since such increments would be impractical, is used to accelerate the learning process. In general, then, the errors are recursively back propagated through the higher layers according to:

\[ \delta_j^{(n)} = \sum_j w_{ji} \delta_j^{(n+1)} P(E_j^{(n)}) \]

(5)

where \( P'(E) \) is the first derivative of \( P(E) \).

Other Spatiotemporal Neural Network Architectures

A number of significant advances in capturing spatiotemporal knowledge with neural network systems have been made to date. See, e.g., M. I. Jordan "Serial Order: A Parallel Distributed Processing Approach", ICS Report 8604, Institute for Cognitive Science, University of California, San Diego, Calif., 1986, and J. L. Elman "Finding Structure in Time", CRL Technical Report 8801, Center for Research in Language, University of California, San Diego, Calif., 1988. Jordan approaches this problem by partitioning the input layer in a connectionist network into separate plan and state layers. In essence, Jordan's architecture acts as a back-propagation network, except for the specialized processing elements in the state layer, which receive their inputs from the output units, as well as from recurrent connections which allow the state layer elements to "remember" the network's most recent state. In other words, the state units behave as "pseudo inputs" to the network providing a past-state history. Here, a recurrent connection is one in which it is possible to follow a path from a processing element back onto itself as shown in FIG. 3. Recurrent networks of this type allow the element's next state to be not only dependent on external inputs, but also upon the state of the network at its most previous time step. In general, however, this network is trained to reproduce a predetermined set of sequence patterns from a static input pattern.

As an example, this network architecture has been used by J. A. Villarel, one of the named inventors herein, in developing a speech synthesizer. The inputs to the speech synthesis network represented a tri-phone combination and the output was partitioned to represent the various vocal tract characteristics necessary to produce speech. Thus, the output layer in the speech synthesis neural network consisted of the coefficients to a time-varying digital filter, a gain element, and a pitch element which excited the filter, and a set of down-counting elements where each count represented a 100 millisecond speech segment. To train a single tri-phone, the network was first reset by forcing the activation value of the tri-phone pattern was then presented to the network's input and held there during the learning process while the outputs changed to produce the appropriate output characteristics for that particular tri-phone combination. The outputs would represent the transition from one phoneme to another while a smooth transition in pitch, gain, and vocal tract characteristics would take place. The process was then repeated for other tri-phone combinations.

As shown in FIG. 4, Elman has modified Jordan's approach by constructing a separate layer, called the "context layer", which is equal in size to the number of units in the hidden layer. In this network the context units receive their inputs along a one-to-one connection from the hidden units, instead of from the output units as described by Jordan. The network works as follows: Suppose there is a sequential pattern to be processed. Initially, the activation values in the context units are reset to a value midway between the upper and lower
SUMMARY OF THE INVENTION

A principal object of the present invention is to provide a processing element for a space-time neural network which is capable of processing temporal as well as spacial data.

A further principal object of the invention is to provide a space-time neural network comprised of a plurality of the aforementioned processing elements, which is capable of processing temporal as well as spacial data. These objects, as well as other objects which will become apparent from the discussion that follows, are achieved, according to the present invention, by replacing the synaptic weights between two processing elements of the type shown in FIG. 2 with an adaptable-digital filter. Instead of a single synaptic weight (which with the standard back-propagation neural network represents the association between two individual processing elements), the invention provides a plurality of weights representing not only association, but also temporal dependencies. In this case, the synaptic weights are the coefficients to adaptable digital filters.

The biological implication of this representation can be understood by considering that synapses undergo a refractory period—responding less readily to stimulation after a response. More particularly, the present invention is realized by providing a processing element (i) for use in a space-time neural network for processing both spacial and temporal data, the network being adapted to receive a sequence of inputs \( X(n), X(n-1), X(n-2), \ldots \), each input \( X(n) \) being comprised of \( N \) components \( x_1(n), x_2(n), \ldots, x_N(n) \). The network comprises the combination of:

(a) a plurality \( L \) of first processing elements, each first processing element \( (i) \) comprising a plurality \( N \) of adaptable filters \( F_{1i}, F_{2i}, \ldots, F_{Ni} \), each filter \( F_{ji} \) having an input \( x_{jin} \), \( x_{j(n-1)} \), \( x_{j(n-2)} \), \ldots, of the sequence of inputs, where \( x_j(n) \) is the most current input component, and providing a filter output \( y_{jin} \) in response to an input \( x_{jin} \) which is given by:

\[
y_{jin} = \sum_{m=0}^{M} a_{jm} y_{j(m)}, b_{jm} f(x_{jm} - k),
\]

where \( a_{jm} \) and \( b_{jm} \) are coefficients of the filter \( F_{ji} \) and \( f \) denotes the action of the filter.

Each first processing element \( (i) \) further comprises a first junction, coupled to each of the adaptive filters, providing a non-linear output \( p(S(n)) \) in response to the filter outputs \( y_{jin} \) which is given by:

\[
p(S(n)) = f(y_{jin}),
\]

where \( f \) denotes the operation of the filter.

In this case each first junction presents a sequence of first output signals,

\[
P(S(n)), P(S(n-1)), P(S(n-2)), \ldots.
\]

The preferred embodiments of the present invention will now be described with reference to the accompanying drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a representational diagram of a classical biological neuron.

FIG. 2 is a block diagram of an artificial neuron or "processing element" in a back-propagation network.

FIG. 3 is a block diagram showing the connection scheme for Jordan's network architecture which learns to associate a static input with an output sequence.

FIG. 4 is a block diagram showing the connection scheme for the Elman network wherein a history of the network's most previous state is stored by transferring the activations in the hidden layer to a pseudo input, context layer. Longer term memories are attainable by adding recurrent connections to the context units.

FIG. 5a and FIG. 5b are representational diagrams of an S-plane and a Z-plane, respectively, illustrating the relationship between the continuous domain S-plane and the discrete domain Z-plane.

FIG. 6a is a block diagram of a digital network for a finite impulse response (FIR) filter.

FIG. 6b is a block diagram of a digital network for an infinite impulse response (IIR) filter.

FIG. 7 is a block diagram of a space-time processing element according to the present invention.

FIG. 8 is a block diagram of a fully connected network utilizing space time processing elements according to the present invention. In this network, a set of input waveform sequences are mapped into an entirely different output waveform sequence.

FIG. 9 is a graph of an error curve for the temporal XOR problem trained in one input element, five hidden element and one output element network with 5 zeros and 0 poles between the input and hidden layers.
and 5 zeros and 0 poles between the hidden and output layers.

passes.

DESCRIPTION OF THE PREFERRED
EMBODIMENTS

Digital Filter Theory Review

Before proceeding with a detailed description of the
Space-Time Neural Network ("STNN") system ac-
cording to the present invention, it is important to intro-
duce digital filter theory and some nomenclature.

Linear difference equations are the basis for the the-
ory of digital filters. The general difference equation
can be expressed as:

\[ y(n) = \sum_{k=0}^{N} b_k x(n-k) + \sum_{m=1}^{M} a_m x(n-m) \]  

(6)

where the \( x \) and \( y \) sequences are the input and output of
the filter and \( a_m \) 's and \( b_k \) 's are the coefficients of the
filter. Sometimes referred to as an s-transform, the well
known continuous domain Laplace transform is an ex-
tremely powerful tool in control system design because of
its capability to model any combination of direct
current (DC) or static levels, exponential, or sinusoidal
signals and to express those functions algebraically. The
s-plane is divided into a damping component (\( \sigma \)) and
a harmonic component (\( j\omega \)) and can mathematically be
expressed as

\[ s = \sigma + j\omega \]  

(7)

This formulation has a number of interesting character-
istics as follows:

1. The general Laplace transfer function can be
thought of as a rubber sheet on the s-plane. A desir-
able transfer function is molded by strategically
placing a transfer function's roots of the numerator
and the denominator in their appropriate positions.
In this case, polynomial roots of the numerator are
referred to as zeros and "pin" the rubber sheet to
the s-plane's ground. On the other hand, polyno-
mial roots of the denominator are referred to as
poles and their locations push the rubber sheet
upwards—much like the poles which hold up the
tarpaulin in a circus tent. Therefore, zeros null out
certain undesirable frequencies and poles can either
generate harmonic frequencies (if close enough to the
j\omega axis) or allow certain frequencies to pass
through the filter.

2. Setting the damping coefficient, \( \sigma \), to zero is ef-
fectively similar to taking a cross sectional cut
along the j\omega axis. This is the well known Fourier
transform.

3. A pole on the j\omega axis, signifying no damping,
produce a pure sinusoidal signal. However, a pole
which travels onto the left half plane of the s-plane
exponentially increases, eventually sending the
system into an unstable state.

The discretized form of the Laplace transform has
been developed further and is referred to as the z-trans-
form. The notation \( z^{-1} \) is used to denote a delay
equal to one sampling period. In the s-domain, a delay of \( T \)
seconds corresponds to \( e^{-sT} \). Therefore, the two vari-
ables \( s \) and \( z \) are related by:

\[ z^{-1} = e^{-sT} \]  

(8)

where \( T \) is the sampling period. The mapping between
the variables can be further illustrated by referring to
FIG. 5. First notice that the left half plane of the s-plane
maps to the area inside a unit circle on the z-plane. In
abiding with the Nyquist criterion, sampling at least
twice the signal bandwidth, \( f_T \) note that as one traverses
from \(-f_T/2\) to \(+f_T/2\) on the s-plane, it is equivalent to
going from \( \pi \) radians toward 0 radians and back to \( \pi \)
radians in a counterclockwise direction on the z-plane.
Furthermore, note that lines in the s-plane map to spi-
rals in the z-plane.

By evaluating the z-transform on both sides of the
linear difference equation, it can be shown that

\[ F(z) = \sum_{k=0}^{N} b_k z^{-k} + \sum_{m=1}^{M} a_m z^{-m} \]

(9)

Digital filters are classified into recursive and non-
recursive types. Filters of the nonrecursive type have
no feedback or recurrent paths and as such all the \( a_m \)
terms are zero. Furthermore, digital filters are also clas-
sified in terms of their impulse responses. Because non-
recursive filters produce a finite number of responses
from a single impulse, such filters are referred to as
"Finite Impulse Response" ("FIR") filters. On the other
hand, the recursive filters produce an infinite number of
responses from an impulse and are therefore referred to
as "Infinite Impulse Response" ("IIR") filters. For exam-
ple, if a unit impulse is clocked through the filter
shown in FIG. 6(a), the sequence

\[ b_0, b_1, b_2, \ldots, b_N, 0, 0, 0, 0, \ldots, 0, 0, 0 \]

will be the output. Notice that the filter produces only
the coefficients to the filter followed by zeroes. How-
ever, if a unit impulse is presented to the filter shown in
FIG. 6(b), because of the recursive structure, the re-
sponse is infinite in duration.

FIR and IIR filters each possess unique characteris-
tics which make one more desirable than the other de-
pending upon the application. The most notable of these
characteristics include:

1. FIR filters, because of their finite duration are not
realizable in the analog domain. IIR filters, on the
other hand, have directly corresponding compo-
nents in the analog world such as resistors, capaci-
tors, and inductive circuits.

2. IIR filters cannot be designed to have exact linear
phase, whereas FIR filters have this property.
Because of their recursive elements, IIR filters are an order of magnitude more efficient in realizing sharp cutoff filters than FIR filters. (4) Because of their nonrecursiveness, FIR filters are guaranteed to be stable. This property makes FIR filters much easier to design than IIR filters. These different properties between FIR and IIR filters must be carefully weighed in selecting the appropriate filter for a particular application.

**DESCRIPTION OF THE SPACE-TIME NEURAL NETWORK**

Having introduced digital filter theory, it is now possible to proceed with the detailed description of the Space-Time Neural Network (STNN) system according to the present invention. What follows is a detailed procedure for constructing and training the STNN. As mentioned earlier, in the STNN system the weights in the subsequent layer. What follows is a detailed description of the STNN system. As asserted earlier, the space-time neural network is comprised of at least two layers of filter elements fully interconnected and buffered by sigmoid transfer nodes in the hidden and output processing elements. A reversal procedure is implemented. Whereas in the forward propagation, input values were clocked into the filter elements, back-propagation instead involves the injection of errors into the filter elements according to the formula:

\[ \Delta b_{ij}(n+1) = \alpha [n] \Delta b_{ij}(n) + (1 - \eta) \delta_j y_i \]

where:

- \( \Delta b_{ij}(n+1) \) is the update for a zero coefficient, \( b_{ij} \), lying between processing elements \( i \) and \( j \).
- \( \alpha \) is the learning rate.
- \( \Delta b_{ij}(n) \) is the most recent update for the \( k \)th zero element between processing elements \( i \) and \( j \).
- \( \eta \) dampens most recent updates.
- \( \delta_j \) is described by (13).
- \( X_j \) contain a history of the output of the \( j \)th neuron in the hidden layer.

The recursive components in each filter element are treated the same way and are updated according to the formula:

\[ \Delta a_{ij}(n+1) = \alpha [n] \Delta a_{ij}(n) + (1 - \eta) \delta_i y_j \]

where:

- \( \Delta a_{ij}(n+1) \) is the update for a pole coefficient, \( a_{ij} \), lying between processing elements \( i \) and \( j \).
- \( \alpha \) is the learning rate.
- \( \Delta a_{ij}(n) \) is the most recent update for the \( k \)th zero element between processing elements \( i \) and \( j \).
- \( \eta \) dampens most recent updates.
- \( \delta_i \) is described by (13).
- \( Y_{jk} \) contain a history of the activation values for the non-recursive filter elements between neurons \( i \) and \( j \), \( k \) time steps ago.

For implementation purposes, the present algorithm only considers the accumulation of errors which span the length of the number of zeroes between the hidden and output processing elements. Thus:

\[ \delta_{ik} = \sum_j P'(E_{ik}) \delta_j y_{jk} \]

where:

- \( \delta_{ik} \) is the error signal at neuron \( i \) for the output layer.
- \( y_{jk} \) ranges over the neuron indices for the output layer.
- \( \delta_j \) is described by (13).

The contributions from the signals flowing into the summing junction are then non-linearly transformed by the sigmoid transfer function:

\[ p(S(n)) = \frac{1}{1 + e^{-S(n)}} \]
that the input patterns 0 0, 0 1, 1 0, and 1 1 pattern is presented which resets the output back to 0 0 state.

Simulations

The space-time neural network according to the present invention was constructed and tested to perform a number of simulations. Source code for a computer program written in "C" language for simulation of the STNN is included in the Appendix below.

The first simulation test was a variation of the classic XOR problem. The XOR is of interest because it cannot be computed by a simple two-layer network. Ordinarily, the XOR problem is presented as a two bit input combination of (00, 01, 10, 11) producing the output (0, 1, 1, 0). This problem was converted into the temporal domain in the following way. The first bit in a sequence was XOR'd with the second bit to produce the second bit in an output sequence; the second bit was XOR'd with the third bit to produce the third bit in an output sequence, and so on, giving the following:

In the simulation, the training data consisted of 100 randomly generated inputs and the outputs were constructed in the manner described above. A network was implemented which had 1 input element, 5 hidden elements and 1 output element and had 5 zero coefficients and 0 pole coefficients between the input and hidden layers and 5 zero coefficients and 0 pole coefficients between the hidden and output layers. The task of the network was to determine the appropriate output based on the input stream. The error curve for the network showing the RMS error in dependence upon the number of training passes is shown in FIG. 9. For a second simulation, a network was implemented with 2 input elements, 8 hidden elements and 8 output elements having 5 zeros and 0 poles between input and hidden, and 5 zeros and 0 poles between hidden and output layers. A problem, called the Time Dependent Associative Memory Test, was constructed which elements having 0 poles between input and hidden layers. A problem, called the Time Dependent Associative Memory Test, was constructed which showed the RMS error in dependence upon the number of training passes is shown in FIG. 10. The error curve for this Time Dependent Associative Memory Test is shown in FIG. 10. As will be seen from FIGS. 9 and 10, the RMS error converged rapidly toward zero.

The final simulation illustrates that the space-time neural network according to the present invention is able to learn the dynamics and model the behavior of a chaotic system. The graph shown in FIG. 11 is a plot of a sine function extending from 0 to π with amplitude π. A "chaotic sequence" can be generated by randomly selecting a value between 0 and π, say xo, determining the value of sin(xo) to produce x1, and repeating this iterative process into a general form represented by x(n+1) = π sin(xn). FIG. 12 shows a collection of x's generated by this process.

The goal of the STNN system in this simulation was to predict a future point, given a history of past points. To keep within the linear bounds of the sigmoid, the sequences collected above were normalized such that the range from 0 to π mapped into the range from 0.2 to 0.8. An STNN system was constructed with 1 input element, 6 hidden elements and 1 output element, with 10 zeros and 0 poles between the input and hidden layers, and 10 zeros and 0 poles between hidden and output layers. The system was trained with 525 data points. Training was periodically suspended to test the system by stimulating it with the sequence of the last 50 samples of the training set—the ordinal values 475 to 525. At this point, the system was prepared to make its first prediction. The predicted value could have been fed back into the input to generate a new predicted value. Instead, the system was fed with actual values generated by the chaos algorithm—that is, ordinal numbers 526 through 625. FIG. 13 illustrates the system's performance at various stages during the training process. FIG. 14 shows the average error of the network's performance during the training process.

Conclusion

The space time neural network (STNN) is a generalization of the back-error propagation network to the time domain. By adopting concepts from digital filtering theory, the network is afforded a distributed temporal memory which permits modeling complex dynamic systems and recognition of temporal sequences as shown in the simulations. The STNN architecture differs from previous work of Jordan and Elman in that the network's memory is distributed over the connections rather than being implemented as a special layer of nodes. This distinction allows the STNN to possess an adaptive temporal memory without introducing additional nonlinearities into the learning law; i.e., the action which occurs on connections between nodes is still
linear, while the nonlinear actions occur within the
nodes.

There has thus been shown and described a novel
space-time neural network for processing both spacial
and temporal data which fulfills all the objects and
advantages sought therefor. Many changes, modifica-
tions, variations and other uses and applications of the
subject invention will, however, become apparent to
those skilled in the art after considering this specifica-
tion and the accompanying drawings which disclose the
preferred embodiments thereof. All such changes, mod-
ifications, variations and other uses and applications
which do not depart from the spirit and scope of the
invention are deemed to be covered by the invention,
which is to be limited only by the claims which follow.

What is claimed is:

1. A processing element (i) for use in a space-time neural network for processing both spacial and temporal data, wherein the neural network comprises a plurality of layers of said processing elements, the plurality of layers comprising a first layer and at least one additional layer, the network further comprising connections between processing elements of the first layer and processing elements of an additional layer; each said processing element adapted to receive a sequence of signal inputs \( X(n), X(n-1), X(n-2), \ldots \), each input \( X(n) \) comprising \( K \) signal components \( x_1(n), x_2(n), \ldots, x_K(n) \), each said processing element comprising, in combination:

   (a) a plurality \( K \) of adaptable filters \( F_1, F_2, \ldots, F_K \) each filter \( F_j \) having an input for receiving
a respective component $x(n)$, $x(n-1)$, $x(n-2)$, . . . of said sequence of inputs, where $x(n)$ is the most current input component, and providing a filter output $y(n)$ in response to the input $x(n)$ which is given by:

$$y(n) = \sum_{m=1}^{N} a_{m} x(n - m) + \sum_{k=0}^{K} b_{k} x(n - k).$$

10. The processing element defined in claim 8, wherein said filters are non-recurrent finite impulse response filters and wherein the response of each filter is given by:

$$\Delta \text{error}_i = \alpha \Delta \text{error}_i^{old} + (1 - \alpha) \text{error}_i x_j (n - k)$$

11. The processing element defined in claim 8, wherein the response of each filter is given by:

$$\Delta \text{error}_i = \alpha \Delta \text{error}_i^{old} + (1 - \alpha) \text{error}_i x_j (n - k).$$

12. The processing element defined in claim 11, further comprising means for adjusting the coefficients $a_{m}$ and $b_{k}$ of each filter $F_j$ in dependence upon the junction output $p(S(n))$.

13. The processing element defined in claim 12, wherein said adjusting means includes means for determining an error in the output $p(S(n))$ between the actual and desired response of the processing element (i) and adjusting the filter coefficients $a_{m}$ and $b_{k}$ of each filter $F_j$ in dependence upon said error.

14. The processing element defined in claim 13, wherein the non-linear transformation is a sigmoid transfer function with output $p(S(n))$ given by:

$$p(S(n)) = \frac{1}{1 + e^{-S(n)}}.$$
each second processing element \( k \) further comprising a second junction, coupled to each of said second adaptive filters of the respective second processing element and providing a non-linear output \( p_k(S_k(n)) \) in response to the filter outputs \( y_k(n) \) which is given by:

\[
p_k(S_k(n)) = f_k(p_k(n)),
\]

where \( S_k(n) \) is the sum of said second filter outputs, each second junction presenting a sequence of second output signals \( p_k(S_k(n)), p_k(S_k(n-1)), p_k(S_k(n-2)), \ldots \)

21. The network defined in claim 20, wherein said non-linear outputs provided by said junctions are a sum \( S_k(n) \) of the filter outputs modified by an arbitrary non-linear transformation \( p_k(S_k(n)) \) to the sum \( S_k(n) \), where \( S_k(n) \) is given by:

\[
S_k(n) = \frac{1}{k} y_k(n).
\]

22. The network defined in claim 21, wherein the non-linear transformation is a sigmoid transfer function given by:

\[
p_k(S_k(n)) = \frac{1}{1+e^{-S_k(n)}}.
\]

23. The network defined in claim 20, wherein said filters are non-linear filters.

24. The network defined in claim 23, wherein said non-linear filters are exponential auto-regressive filters.

25. The network defined in claim 20, wherein said adaptable filters are digital filters.

26. The network defined in claim 25, wherein said filters are linear filters.

27. The network defined in claim 26, wherein said filters are recursive, infinite impulse response filters and wherein the response of each filter is given by:

\[
y_k(n) = \sum_{m=1}^{M} c_{mj} y_k(n-m).
\]

28. The network defined in claim 26, wherein said filters are non-recursive finite impulse response filters and wherein the response of each filter is given by:

\[
y_k(n) = \sum_{k=0}^{N} d_{kj} x_k(n-k).
\]

29. The network defined in claim 26, wherein the response of each filter is given by:

\[
y_k(n) = \sum_{m=1}^{M} c_{mj} y_k(n-m) + \sum_{k=0}^{N} d_{kj} x_k(n-k).
\]

30. The network defined in claim 29, wherein the coefficients \( c_{mj} \) and \( d_{kj} \) of each filter \( F_j \) are adjustable.

31. The network defined in claim 29, further comprising means for adjusting the coefficients \( c_{mj} \) and \( d_{kj} \) of each filter \( F_j \) in dependence upon the plurality \( N \) of junction outputs \( p_j(S_j(n)) \).

32. The network defined in claim 31, wherein said adjusting means includes means for determining and error in said outputs \( p_j(S_j(n)) \) between the actual and desired response of the network and adjusting the filter coefficients \( c_{mj} \) and \( d_{kj} \) of each filter \( F_j \) in dependence upon said error.
33. The network defined in claim 32, wherein the non-linear transformation is a sigmoid transfer function given by:

\[ p'(S_g(n)) = \frac{1}{1 + e^{-S_g(n)}}. \]

\[ \Delta_{d_{jk}} = \alpha \Delta_{d_{jk}} \text{old} + (1 - \alpha) \Delta_{d_{jk}}(n-k) \]

\[ \Delta_{a_{jk}} = \alpha \Delta_{a_{jk}} \text{old} + (1 - \alpha) \Delta_{a_{jk}}(n-k) \]

\[ \alpha \text{ is the learning rate of the neural network} \]

where:

\[ \Delta_{d_{jk}} \text{ is the update for the kth zero coefficient, } d_{jk} \text{, lying between first processing element } j \text{ and second processing element } i \]

\[ \Delta_{a_{jk}} \text{ is the update for the kth pole coefficient, } a_{jk} \text{, lying between first processing element } j \text{ and second processing element } i \]

\[ \alpha \text{ is the learning rate of the neural network} \]

\[ \Delta_{d_{jk}} \text{old} \text{ is the most recent update for the kth zero element between first processing element } j \text{ and second processing element } i \]

\[ \Delta_{a_{jk}} \text{old} \text{ is the most recent update for the kth pole element between first processing element } j \text{ and second processing element } i \]

\[ \eta \] damps the most recent update

\[ p'(S_g(n)) \text{ is the first derivative of the non-linear transfer function for the gth output's activation value or in the case of said sigmoid non-linear transfer function, } p'(S_g(n)) = \frac{1}{1 + e^{-S_g(n)}}. \]

34. The network defined in claim 33, wherein said error is given by:

\[ \delta_j = (D_j(n) - A_j(n)) \]

\[ p'(S_g(n)) \]

where:

\[ D_j(n) \text{ is the nth desired response from a given sequence for neuron } g \text{ at the output layer} \]

\[ A_j(n) \text{ is the network's output response at neuron } g \text{ for the nth input sequence pattern} \]

\[ p'(S_g(n)) \]

\[ p'(S_g(n)) = \frac{1}{1 + e^{-S_g(n)}}. \]

\[ \Delta_{d_{jk}} = \alpha \Delta_{d_{jk}} \text{old} + (1 - \alpha) \Delta_{d_{jk}}(n-k) \]

\[ \Delta_{a_{jk}} = \alpha \Delta_{a_{jk}} \text{old} + (1 - \alpha) \Delta_{a_{jk}}(n-k) \]

35. The network defined in claim 34, wherein the kth zero coefficient \( d_{jk} \) of the filter between first processing element \( j \) and second processing element \( i \) is adjusted in accordance with the formula:

\[ \Delta_{d_{jk}} = \alpha \Delta_{d_{jk}} \text{old} + (1 - \alpha) \Delta_{d_{jk}}(n-k) \]

\[ \Delta_{a_{jk}} = \alpha \Delta_{a_{jk}} \text{old} + (1 - \alpha) \Delta_{a_{jk}}(n-k) \]

where:

\[ \Delta_{d_{jk}} = \alpha \Delta_{d_{jk}} \text{old} + (1 - \alpha) \Delta_{d_{jk}}(n-k) \]

\[ \Delta_{a_{jk}} = \alpha \Delta_{a_{jk}} \text{old} + (1 - \alpha) \Delta_{a_{jk}}(n-k) \]

\[ \alpha = \text{the learning rate of the neural network} \]

\[ \Delta_{d_{jk}} \text{old} = \text{the most recent update for the kth zero element between first processing element } j \text{ and second processing element } i \]

\[ \Delta_{a_{jk}} \text{old} = \text{the most recent update for the kth pole element between first processing element } j \text{ and second processing element } i \]

\[ \eta = \text{damps the most recent update} \]

\[ y_{g}(n-k) = \text{the activation value for the filter element between first processing element } j \text{ and second processing element } i, \text{ k time steps in the past} \]

36. The network defined in claim 34, wherein the kth pole coefficient for said filter between first processing element \( j \) and second processing element \( i \), \( a_{jk} \), is adjusted in accordance with the formula:

\[ \Delta_{a_{jk}} = \alpha \Delta_{a_{jk}} \text{old} + (1 - \alpha) \Delta_{a_{jk}}(n-k) \]

\[ \Delta_{a_{jk}} = \alpha \Delta_{a_{jk}} \text{old} + (1 - \alpha) \Delta_{a_{jk}}(n-k) \]

\[ \eta = \text{damps the most recent update} \]

\[ y_{g}(n-k) = \text{the activation value for the filter element between first processing element } j \text{ and second processing element } i, \text{ k time steps in the past} \]

37. The network defined in claim 34 wherein said filter coefficients \( a_{jk} \) and \( d_{jk} \) are adjusted in accordance with the formulae:

\[ \Delta_{d_{jk}} = \alpha \Delta_{d_{jk}} \text{old} + (1 - \alpha) \Delta_{d_{jk}}(n-k) \]

\[ \Delta_{a_{jk}} = \alpha \Delta_{a_{jk}} \text{old} + (1 - \alpha) \Delta_{a_{jk}}(n-k) \]

\[ \alpha = \text{the learning rate of the neural network} \]

\[ \Delta_{d_{jk}} \text{old} = \text{the most recent update for the kth zero element between first processing element } j \text{ and second processing element } i \]

\[ \Delta_{a_{jk}} \text{old} = \text{the most recent update for the kth pole element between first processing element } j \text{ and second processing element } i \]

\[ \eta = \text{damps the most recent update} \]

\[ y_{g}(n-k) = \text{the activation value for the filter element between first processing element } j \text{ and second processing element } i, \text{ k time steps in the past} \]

38. The network defined in claim 34, wherein the kth pole coefficient for said filter between network input element \( j \) and first processing element \( i \), \( a_{ij} \), is adjusted in accordance with the formula:

\[ \Delta_{a_{ij}} = \alpha \Delta_{a_{ij}} \text{old} + (1 - \alpha) y_{j}(n-k) \]

\[ \Delta_{a_{ij}} = \alpha \Delta_{a_{ij}} \text{old} + (1 - \alpha) y_{j}(n-k) \]

where:

\[ \Delta_{a_{ij}} = \text{the update for the kth pole coefficient, } a_{ij}, \text{ lying between network input element } j \text{ and first processing element } i \]

\[ \alpha = \text{the learning rate of the neural network} \]

\[ \Delta_{a_{ij}} \text{old} = \text{the most recent update for the kth pole coefficient between network input element } j \text{ and first processing element } i \]

\[ \eta = \text{damps the most recent update} \]

\[ y_{j}(n-k) = \text{the output of the jth first processing element } k \text{ time steps in the past} \]

39. The network defined in claim 34 wherein said filter coefficients \( a_{jk} \) and \( b_{jk} \) are adjusted in accordance with the formulae:

\[ \Delta_{b_{jk}} = \alpha \Delta_{b_{jk}} \text{old} + (1 - \alpha) y_{j}(n-k) \]

\[ \Delta_{b_{jk}} = \alpha \Delta_{b_{jk}} \text{old} + (1 - \alpha) y_{j}(n-k) \]

\[ \alpha = \text{the learning rate of the neural network} \]

\[ \Delta_{b_{jk}} \text{old} = \text{the most recent update for the kth zero coefficient between network input element } j \text{ and first processing element } i \]

\[ \eta = \text{damps the most recent update} \]

\[ y_{j}(n-k) = \text{the output of the jth first processing element } k \text{ time steps in the past} \]
45

$y_d(n-k)$ is the activation value for the filter element between network input element $j$ and first processing element $i$, $k$ time steps in the past.

40. The network defined in claim 34, wherein the $k$th zero coefficient $b_{ijk}$ of the filter between network input element $j$ and first processing element $i$ is adjusted in accordance with the formula:

$$\Delta b_{ijk} = \alpha [n \Delta b_{ijk}^{old} + (1 - \alpha) x_j y_k (n-k)]$$

where:

- $\Delta b_{ijk}$ is the update for a zero coefficient, $b_{ijk}$, lying between network input element $j$ and first processing element $i$.
- $\epsilon_i$ is the backpropagated network error at the $i$th first processing element.
- $\alpha$ is the learning rate of the neural network.
- $\Delta b_{ijk}^{old}$ is the most recent update for the $k$th zero coefficient between network input element $j$ and first processing element $i$.
- $\gamma$ damps the most recent update.
- $x_j(n-k)$ is the $j$th network input $k$ time steps in the past.

41. The network described in claim 33, further comprising a means for propagating the error $\Delta \epsilon (n)$ measured at the outputs of the $g$th second processing element backward through the intervening filter connections between first and second processing elements thereby to provide a means for adjusting the coefficients of the filters which connect the inputs of the network to the first processing elements.

42. The network defined in claim 38, wherein said means for backward propagation of error is described by the formula:

$$\epsilon_i(n) = f(S_i(n)) \left[ \sum_{j=0}^{T} d_{ijk} \epsilon_i (n+k) + \sum_{j=1}^{U} c_{ijk} y_j(n-k) \right]$$

where:

- $\epsilon_i(n)$ is the result of backward propagation of network error from the outputs of all second processing elements through the filters between first processing element $i$ and the plurality $N$ of second processing elements.
- $c_{ijk}$ is the $k$th pole coefficient of the filter between first processing element $i$ and second processing element $j$.
- $d_{ijk}$ is the $k$th zero coefficient of the filter between first processing element $i$ and second processing element $j$.
- $T$ and $U$ are respectively the non-recursive and recursive orders of the filter through which back-propagation occurs.
- $\Delta \epsilon(n+k)$ is the error computed at the output of the $j$th second processing element $k$ time steps in the future.
- $y_j(n-k)$ is the output from $k$ time steps in the past of the filter operating on the inverted sequence of network errors.
