INTRODUCTION

America's next major step into space will be the construction of a permanently manned Space Station which is currently under development and scheduled for full operation in the mid-1990s. Most of the construction of the Space Station will be performed over several flights by suited crewmembers during an extravehicular activity (EVA) from the Space Shuttle. Once fully operational, EVAs will be performed from the Space Station on a routine basis to provide, among other services, maintenance and repair operations of satellites currently in Earth orbit.

BACKGROUND

When a crewmember ventures outside the spacecraft, an extravehicular activity (EVA) is performed. To perform an EVA from the Space Shuttle, an astronaut must don an extravehicular mobility unit (EMU) — a space suit assembly and portable life-support backpack that provides, respectively, the pressure retention and habitable atmosphere that a human requires to perform a productive umbilical-free EVA in the vacuum of space. Attached to the front of the Shuttle EMU shown in Figure 1 is a display and control module (DCM), a large chestpack with life-support controls and a 12-character red LED display located just beneath the helmet visor. Through the DCM display, the astronaut is able to read various life-support parameters (e.g., oxygen pressure, suit pressure, etc.). These parameters are continuously measured and monitored by a caution and warning system (CWS) microcomputer located within the backpack. If any anomalous conditions are detected, caution or warning messages are generated and then relayed from the CWS to the EVA crewmember via the DCM display. Should any of these messages be reported by the CWS, the astronaut then refers to corrective instructions in the EMU cuff checklist, a "flip-through" reference booklet attached to the wrist of the suit. (In addition to these corrective instructions, the cuff checklist also contains information about general mission procedures and EVA equipment operation.)

LIMITATIONS TO THE SHUTTLE EMU INFORMATION SYSTEM

Although several spectacular EVAs have been performed from the Shuttle, a number of limitations with the Shuttle EMU information-exchange system have been identified. These limitations relate to the DCM visibility, information accessibility, information capacity, and the DCM size. Both the display and the controls on the DCM are difficult to view. The location of the DCM display requires the crewmember to look down at an uncomfortable angle. Since its viewing distance is so small, some astronauts require the use of a special lens to read the characters. In addition, bright environments "wash out" the red LED characters, sometimes forcing the crewmember to cup his hands over the display for viewing. Difficulties also exist in viewing the controls located on the front of the DCM, requiring the EVA crewmember to wear a wrist mirror to read the reflected images.

Information retrieval during EVA must be manually sequenced. The astronaut must
toggle a switch to receive each 12-character line of DCM data, and referring to the cuff checklist is a two-hand operation.

The amount of data that may be presented is severely limited. The entire library available during EVA consists of a number of twelve-character messages (an astronaut would have to toggle 24 times just to read this paragraph) and 40 to 50 pages of a 3.25-inch x 4.5 inch cuff checklist.

The DCM not only invades the astronaut's prime work envelope (i.e., the area directly in front of the chest), but its mere presence has restricted improvements to the reach capability and arm mobility of the EMU.

The DCM not only invades the astronaut's prime work envelope (i.e., the area directly in front of the chest), but its mere presence has restricted improvements to the reach capability and arm mobility of the EMU.

INFORMATION SYSTEM IMPROVEMENTS

Although the DCM and cuff checklist are suitable for the occasional EVAs performed from the Shuttle, the nearly routine EVA anticipated for the Space Station dictates that productivity be maximized. Ideally for Space Station EVA, the access to information should be a "hands-free" operation, especially for labor-intensive EVA scenarios such as satellite servicing, unplanned maintenance, or emergency operations. Furthermore, the display medium should support text, graphical, and video formats in all EVA environments. To meet these ambitious goals, NASA is developing a voice recognition and control system to provide "hands-free" operations and a helmet-mounted projection device to display information to the EVA crewmember.

Although space is inherently a harsh environment, the rather benign conditions inside the EMU facilitate the use of speech recognition technology. First, sounds within the EMU are absent of noises that commonly cause problems for speech recognizers, such as background voices and extraneous clamor found at industrial workstations or breathing noises inherent with masked fighter pilots. The EMU helmet contains only fan and airflow noises which are high-frequency sounds that can be easily filtered. Second, an extensive vocabulary is not required for the EMU since a vocabulary of about 50 words will suffice for the procedurally oriented tasks of EVA. Furthermore, even though a connected-word recognizer may allow more flexibility, an isolated-word recognizer is all that is necessary. Finally, the voice recognition system need not be speaker-independent to allow multiple users since each EVA-qualified crewmember aboard the Space Station will have an EMU. Similar to military helmet-mounted and heads-up displays, the EMU helmet-mounted display (HMD) consists of projection optics and image/illumination source electronics that permit convenient viewing of text, graphics, and video on a transparent display deposited onto the helmet visor. With a transparent screen, the astronaut can read information overlaid onto the real world when the HMD is active. When the HMD is off, the screen is practically invisible. Displayed images are located conveniently above the astronaut's prime field-of-view to prevent visual interference while performing EVA tasks.

Through control system electronics, the voice recognizer can select imagery on the HMD, thus providing a powerful and valuable tool for the Station EVA astronaut (other functions are also available). The combined system will
replace the need for the DCM, the cuff checklist, and the EMU wrist mirror, thus enhancing EVA productivity while sacrificing none of their services.

With the HMD and the aid of a voice recognition system, almost unlimited amounts of information are conveniently available to the astronaut during the EVA. The astronaut may review EMU status information, receive EMU alarms with corrective action, obtain general EVA operational information (previously supplied by the cuff checklist), control EMU switches by voice, monitor transmissions from the astronaut's personal TV camera, and access the Station's main computer (which can provide data retrieval from onboard memory or a ground database).

**NASA EVA SIMULATION**

At the NASA Johnson Space Center, the data available to a Space Station EVA astronaut may be simulated in an Advanced EVA Systems Laboratory. This simulation concentrates on the anticipated Space Station EMU data logic flow required to efficiently provide the EVA crewmember with various informational types while maximizing the usefulness of the voice recognition/control system and helmet mounted display. The simulation program is run on a Macintosh II and operates in conjunction with a bench model of the HMD and a speaker-dependent voice recognition system. The simulation allows the user to perform the pre-EVA series of checklists required to exit the spacecraft, offers the user all informational data types (including alarms) available during the EVA, and provides the series of checklists to return safely inside the vehicle. Below is a brief description of the simulation program.

**PRE-EVA**

Pre-EVA procedures are performed within the airlock prior to exiting the spacecraft. After the EMU is donned and powered up, the HMD supports a preparation mode where the astronaut user is led through a series of checks prior to depressurizing the airlock. Detailed instructions including illustrations for depressurization and subsequent airlock egress are provided. In the simulation, the pre-EVA HMD screens are split into three fields (excluding the header). The top field contains procedural information, the middle field contains a series of switches that may be manipulated by voice, and the bottom field lists valid functions selectable by voice. The pre-EVA checks and switch manipulations are controlled by voice commands. The following is the sequence of events required to perform the pre-EVA operation. (Note the quoted commands spoken by the user.)

1. Simulating power applied to the EMU, the HMD will display a power restart message and a Systems Check of the EMU (See Figure 2).

2. Following the systems status check (and if OK), the first page of the pre-EVA file is shown (see Figure 3). The crewmember is directed to turn the EMU fan on and then to
pressurize the suit. To activate the fan, the crewmember simply says "FAN ON." The FAN block in the middle field will then toggle position. In a similar fashion, the suit is pressurized by first selecting "O2 ACTUATOR" followed by "PRESS." After the suit is fully pressurized, the next page, suit leak check, will be shown.

(3) A leak check (to determine suit integrity) is performed automatically in the simulation. During the leak check simulation, a status of the check including time left, suit pressure, and O2 actuator positions are displayed (See Figure 4). The leak check may be aborted in progress by saying "EXIT." An aborted leak check may be either restarted ("ACKNOWLEDGE") or by-passed entirely ("CONTINUE"). An unaborted leak check with positive results is shown in Figure 5. (Note that a second test, if desired, can be conducted by saying "ACKNOWLEDGE.")

(4) By saying "CONTINUE," the crewmember will proceed to the Airlock Depress Checklist, a series of procedures to depressurize the airlock to vacuum (see Figure 6). Note the use of graphics. (A "GO BACK" command at this point will display Figure 5, but will not redo the actual check unless the previous leak check was aborted or was not satisfactory.) By saying "CONTINUE" again, the crewmember will enter the second page of the checklist (see Figure 7). Note that airlock pressure is located within the checklist step requiring the monitoring.

Figure 4. Pre-EVA Leak Check (in-progress)

Figure 5. Pre-EVA Leak Check (completed)

Figure 6. Airlock Depress Checklist (page 1)

Figure 7. Airlock Depress Checklist (page 2)
(5) Once the simulated depressurization to vacuum is accomplished, the crewmember will "CONTINUE" to the Pre-Egress Checklist (see Figure 8). (Note that the crewmember may switch several controls with a single voice command.) Once he has completed this checklist, he will "CONTINUE" to the Egress Checklist (Figure 9). The Pre-Egress and Egress procedures lead the crewmember safely out of the airlock to perform the actual EVA. After the final page of this checklist has been read, an "EXIT" command will display the Normal EMU Status page for use during the EVA.

EMU Status - The EMU Status file is the base state of the simulation program. Each page is split into two fields (excluding the header) as shown in Figure 10. The top field displays specific EMU parameters and consumable values in two formats: on a quick-read bar graph format and actual (or calculated) values. This method allows the astronaut to quickly and accurately assess the performance of the EMU. The lower field lists valid available functions.

EMU Operational Information - This subroutine allows the astronaut to select and read various data files from a main menu by voice commands. By saying "MAINTENANCE," the user obtains the menu as shown in Figure 11. This file and the "CHECKLIST" file...
provide information about maintenance procedures, equipment operation, and contingency or troubleshooting flow charts, among other information subfiles in text and graphical formats. Once accessed, the user may page back and forth through the file. As an example, if "THREE" were selected, the crewmember would retrieve the "PAM Large Sunshield" file, which details a procedure for installing "sunglasses" on the Space Shuttle's windows. Page one of the "PAM Large Sunshield" file lists the tools the EVA crewmember must collect to perform the job (see Figure 12). From here, the astronaut may "CONTINUE" to obtain the next page of information. An "EXIT" within a file would bring the user back to the main menu. Another "EXIT" would bring the user to the base state, the first Status page.

**EMU Switch Manipulation** - (This procedure is identical to that described in the pre-EVA section.)

**EMU Camera Monitoring** - Shuttle EVA astronauts are not capable of monitoring TV cameras. They depend on ground or Shuttle communication for feedback on pointing the camera. On the other hand, with the Station EMU, an astronaut can say "CAMERA" and receive live video from his TV camera directly on his HMD. Currently the simulation program only displays still graphics to the user. An enhancement to the simulation program will soon be added to allow the crewmember to move and position a camera by voice.

**Accessing Information From The Station** - From the Station's central computer, the EVA astronaut may receive unlimited amounts of information via a radio frequency link to the crewmember. This information, in the form of files, will be accessed by the EVA crewmember much like the operational information described above. These files may have been produced prior to launch, prior to the EVA by that astronaut, or by someone on the ground to be transmitted, real-time, to an EVA astronaut. A procedure to simulate this function is currently being developed.

**Other Functions** - Other functions are also available to the crewmember while receipt of alarms with corrective action, notifying Station astronauts of anomalous conditions (which includes an option for sending them EMU transmitted data), a complete recognizer vocabulary menu, and updating voice templates by voice.

**Post-EVA** - To complete the EVA, the astronaut enters the airlock and connects his umbilical line to the EMU. Post-EVA instructions are provided to the crewmember via the HMD and are basically a reverse sequence of the pre-EVA set of events, concluding with a power-down and doff of the EMU.
CONCLUSION

Both voice recognition and helmet-mounted display technologies can improve the productivity of workers in space by potentially reducing the time, risk, and cost involved in performing manned extravehicular activity. NASA has recognized this potential and is currently developing a voice-controlled information system for Space Station EVA. Two bench-model helmet-mounted displays and an EVA simulation program have been developed to demonstrate the functionality and practicality of the system.
