1.0 Introduction

The University of Dayton is pleased to submit this annual report to the National Aeronautics and Space Administration (NASA) Langley Research Center which documents the development of an Operations and Support (O&S) Cost model as part of a larger Life Cycle Cost (LCC) structure. It is intended for use during the conceptual design of new launch vehicles and spacecraft. This research is being conducted under NASA Research Grant NAG-1-1327. This research effort changes the focus from that of the first two years in which a reliability and maintainability model was developed to the initial development of an operations and support life cycle cost model. Cost categories were initially patterned after NASA's three axis work breakdown structure consisting of a configuration axis (vehicle), a function axis, and a cost axis. A revised Cost Element Structure (CES), which is currently under study by NASA, was used to established the basic cost elements used in the model. While the focus of the effort was on operations and maintenance costs and other recurring costs, the computerized model allowed for other cost categories such as RDT&E and production costs to be addressed. Secondary tasks performed concurrent with the development of the costing model included support and upgrades to the Reliability and Maintainability (R&M) model. The primary result of the current research has been a methodology and a computer implementation of the methodology to provide for timely operations and support cost analysis during the conceptual design activities.

1.1 Research Objectives

The major objectives of this research are:

a. to obtain and to develop improved methods for estimating manpower, spares, software and hardware costs, facilities costs, and other cost categories as identified by NASA personnel;

b. to construct an operations and support cost model of a space transportation system for budget exercises and performance-cost trade-off analysis during the conceptual and development stages,

c. to continue to support modifications and enhancements to the R&M model;

d. to continue to assist in the development of other models and to support analysis activities in the study of proposed space systems.
1.2 Status of research tasks

The following tasks, as defined in the proposal, have been completed:

Task 1. (Problem Definition) Cost categories for inclusion in the cost model have been identified. These costs are based upon the three axis work breakdown structure and will include recurring hardware, software, facilities, and manpower costs. Hardware includes vehicle spares and expendables as well as ground support equipment. A proposed Cost Element Structure (CES) pertaining to the operations and support costs has formed the basis for the cost model described below. This cost structure is discussed in Section 2.0 and is recommended to NASA for use in all LCC processes.

Task 2. (Literature Search) An extensive literature review to determine existing methodologies for estimating costs in each of the major categories identified in Task 1 has been completed. Many of the cost estimating relationships identified during this task has been utilized in the operations and support cost model. Primarily Defense Department and contractor life cycle costing models have provided cost data and parametric cost relationships relevant to this study. Section 3.0 summarizes these references and compares and contrasts various LCC models. A completed bibliography is also provided.

Task 3. (Data Collection) From Task 1 and Task 2, it was determined that existing cost models did not adequately address facilities costs. In addition, the uniqueness of the space operations at both Cape Canaveral and the Johnson Space Center necessitated the use of Shuttle and contractor supplied cost data to support the development of new cost estimating relationships. In particular, data to support the life cycle costing of facilities has been obtained from the Air Force. This data and the resulting methodology is described in Section 5.0.

Task 4. (Data Analysis) Parametric cost estimating equations based upon the facilities data obtained in Task 3 have been developed. These equations are documented in Section 5.0. Section 4.0 describes the general methodology utilized in the cost model. This methodology is a result of the insight obtained from the three previous tasks.

Task 5. (Model Development) Based upon the CES and the available and derived parametric cost equations, an initial operations and support cost model has been developed. The model has been structured to include RDT&E costs, investment or acquisition costs and operations costs as inputs in order to provide for a complete cost analysis. However, the model will compute most of the support (maintenance and logistics) costs from various input parameters. This model includes inflation factors and will compute costs inflated to a given base year or compute costs in then year (inflated) dollars. The cost model utilizes output from the R&M model.

Task 6. (Model Implementation) A PC model has been completed for NASA's to use on a trial basis. Updates and revisions to the model are expected. This program is written in compiled BASIC and is compatible with the previously developed R&M model.
Task 7. (R&M Upgrade) Several changes have been accomplished to the R&M model. These include (1) using a weighted average to compute the vehicle manhour per maintenance action factor, (2) redefining ground processing and ground power-on times, (3) converting pad and integration time from hours to days, (4) changing the input parameter from flights per month to flights per year, (5) computing an air abort rate (not integrated into model), (6) computing the number of maintenance crews to be assigned, (7) providing a hard copy reports generator module, (8) revising the method used to account for main engine redundancy, and (9) establishing procedures for the user to specify a subsystem reliability rather than have the model compute one. This last upgrade was significant in that it required reverse engineering the computation of a mean time between maintenance actions in order to provide consistent maintenance manhours, manpower, spares, and vehicle turntime calculations.

Task 8. (Simulation Support) This task has been deferred and will be addressed as part of the follow-on integration effort.
2.0 Cost Element Structure (CES)

A cost element structure (CES) is a methodical representation of the economic activities which make-up an economic entity. The purpose of the structure is to provide visibility to the costs of interest. The cost element structure provides a hierarchial ordering of the costs where the greatest detail is rolled-up into ever higher and larger aggregation of costs. The degree of cost roll-up necessary is dependant upon the initial cost detail and structure. A cost element structure can be used to track the ongoing operations of an economic entity or to predict the future financial condition of an economic entity.

2.1 Program Categories

To track the economic activity of a program the most commonly used cost element structure, in government projects, matches the CES used in how the money is received from the funding organization or congress. This matching of cost categories extends to the level of detail required by the management structure of the organization working the project and the funding organization's requirements. The costs at the lowest level (greatest detail) of the cost element structure is determined by one of two methods, actual cost figures (if they are available) or estimates of the cost figures (typically used in estimating a conceptual program or early in the life cycle of the program). The method used is determined by the availability and quality of actual cost data to be used in the predictive model. A schematic representation of the program phase and estimation technique is shown below.

![Figure 1 Cost Estimation Technique](image-url)
A production program goes through a well defined sequence of stages. Briefly, the stages are:

**Concept Development** - Initial definition of the program elements and the structure of the systems composing the program at a gross level. Technologies are identified and the general subsystem operational parameters and requirements are identified.

**Demonstration/Validation (DEM/VAL)** - Refinement of the system parameters with the production of test article(s) for further verification of the ability to meet the requirements with the current design. System parameters are relatively well defined and the costs of the systems are becoming more complete.

**Full Scale Early Deployment (FSED)** - Initial production runs of the system where system parameters are well defined and the costs well understood.

**Production** - Full production of the system. The system costs are known and the system parameters are fixed. Operational costs can be estimated accurately at this point.

**Operations** - The system has entered service and all the costs associated with the system are known and the operational cost are being developed.

An alternative method to define the system stages and the comparison to the system method shown are Research and Development (concept development and dem/val), Production (FSED and production), Operating and Support (operations), and Disposal. The alternative system stage definitions are given in the discussion below.

**Research and Development** are those costs associated with research, development, test, and evaluation of system hardware and software. More specifically, it includes the cost of feasibility studies; simulation or modeling; engineering design, development, fabrication, assembly, and test of prototype hardware; initial system evaluation; associated documentation; and test of software.

**Production** are those costs associated with producing the system, initial support equipment, training, technical and management data, initial spares and repair parts, plus any other items required to introduce a new system.

**Operating and Support** is the cost of personnel, material, and facilities of both a direct and indirect nature required to operate, maintain, and support the hardware and software of the system.

**Disposal** is the cost associated with disposing of a system at the end of its useful life, minus any salvage value. This category is seldom estimated in most analyses. Often this value is very small in comparison to the other three cost categories.
The descriptions of the two different representations of the life cycle of a project parallel each other very closely. The primary difference is emphasis placed in the first representation on the early phases of a program while the second includes the cost of disposal of the system. In order to follow the guidance of DoD's cost analysis improvement group (CAIG) we will

2.2 Cost Estimating Techniques

The cost estimating techniques (shown in figure 1, of section 2) are based upon the actual program cost information available to the analyst at that particular stage of the program. The use of parametric cost techniques occurs early in the program when the system is poorly defined and the actual cost can only be estimated, based upon previous systems. This estimation must be done carefully to avoid problems which will be discussed later. As the program progresses the degree of uncertainty in the design decreases and the reliance on cost estimating relationships (CER's) diminishes.

Analogy cost analysis (or historical rates and percentages) requires a well defined program and system that is compared with similar projects to arrive at an estimate of the program cost. The analyst must use caution in applying the analogy and determining the correct allowances for differences between the two programs and systems.

Engineering cost estimates may be the most difficult and time consuming to determine. Almost complete cost data must be available for the smallest component to the largest system. This is a "bottom-up" analysis of costs. The cost at the lowest level of the system (component or individual) is accounted for and then rolled-up into course divisions of cost. The process requires handling a large volume of data in minute detail. This is the beginning of an "accounting" type of cost estimating.

Actual cost analysis relies on a rapidly maturing program where the requirements are fixed and the system is in initial production. Until the system is disposed of a system's cost will never be calculated entirely by the actual method. The disposal cost are unknown exactly until the disposal is performed. So even entering the disposal phase of a systems life cycle there will be some engineering estimates required to develop the costs of the system at this stage.

The accounting method relies upon a relative static financial entity with known historical costs. The use of cost estimating relationships (CER's) to predict costs requires historical cost data for similar financial entities and the best guess as to how the costs of the current financial entity differ from those which comprise the historic cost database from which the CER's were developed. The user of the CER must understand the limitation imposed upon the CER by the data from which the CER was estimated. Estimating costs with parameters outside of the original database must be approached with caution. Extrapolation of cost data is highly dependent upon the mathematical structure of the CER rather than the underlying historical data.
2.3 Three-Axis Model

NASA (LRC) has developed a useful conceptual cost model which will be referred to as the three-axis LCC model. The three axis are: (1) phase (e.g. development, production), (2) system (e.g. vehicle structure, engines), and (3) cost category (e.g. hardware, personnel). A general view of this model is shown on the next page. The three dimensional format of the model allows rapid investigation of different relationships depending upon which face of the "cube" is investigated and at what level. The implementation of the "cube" requires more thought and planning than a more traditional "flat" presentation. The additional planning is a result of resolving the interrelationships (where the three axis cross) and to ensure proper the cell contains the appropriate cost formula. The information required to fill a cubic presentation with appropriate formulas at each intersection of the cell faces may not always be available or appropriate. This results in many empty cells. The result is that in some cases the effort required to develop a cubic presentation is not justified in terms of the additional information to be gained by studying the interrelationships between the different cube faces and what cell intersections are used. The degree to which each cell in the cube is filled is dependent upon the degree of refinement in the data used in creating the formulas in each cell. The cubic format lends itself to the representation of the interrelationships of data if information to fall the cells is abundant and of a high quality. The three-axis model has proven to be a useful conceptual model with which to identify the relevant cost elements. However, in implementing the described model, the more traditional linear approach has been adopted.

Manpower, etc. required to process the booster through the facility

Moris 12
2.4 Cost Element Structure

Table 2-1 represents the linear Cost Element Structure (CES) currently being considered by NASA for the purpose of conducting Life Cycle Costing. This structure has been adopted for use in this study recognizing that changes will probably occur. However, the structure has presented here provides the appropriate level of detail for implementing the costing methodology discussed in Section 4.0.

2.4 Program Phasecost
3.0 Life Cycle Cost (LCC) Models

3.1 Relevant Life Cycle Models

A review of the existing life cycle cost models literature was conducted by searching computerized databases of periodic and published manuscripts. These included library, Defense Technical Information Center (DTIC) and NASA holdings. The library holdings and the periodic literature were mostly generic methodologies on developing LCC models or predicting the production cost of a large number of consumer articles. There was very little utility in these references except as general background material. The DTIC and NASA documents were more illuminating.

The NASA and DTIC documents discussed high-tech systems in a low-production environment and their life cycle costs. The library references did not address the unique aspects of this type of system. The economic environment of a space vehicle is that the prototype or engineering built article will be a significant fraction of the number of vehicles constructed. The NASA and DTIC documents did include references to systems built in such an environment.

From the many references in the bibliography there are a few which are especially noteworthy for their direct application to the development of cost estimating relationships for conceptual design space vehicles. These references include:

1) AFI 655-03 (former AFR 173-13)
2) Conceptual Design & Analysis of Hypervelocity Aerospace Vehicles: Volume 5 - Cost (HVL)
4) Life Cycle Cost User’s Manual (HVLCCM)
5) Modular Life Cycle Cost Model (MLCCM) for Advanced Aircraft Systems
6) NATO: Software Life Cycle Costing
7) Naval Fixed Wing Aircraft Operating and Support Cost Estimating Model
8) PREVAIL: Algorithms for Conceptual Design of Space Transportation Systems (PREV)
9) Strategic Missile (Minuteman) Operating and Support Cost Factors (STRAMICE)
10) Unmanned Space Vehicle Cost Model, Sixth Edition (SD TR-88-97)
11) A New Approach to Modeling the Cost of Ownership for Aircraft Systems (MACO)
12) Logistics Cost Analysis Model (LOG)
13) Reliability and Maintainability Model (RAM)

All but the last two references are addressed in detail in Appendix A and all are discussed briefly below. The last two reference were developed specifically for NASA’s use and are adequately documented separately.

3.1.1 AFI 655-03 (former AFR 173-13), reference 1, is a compilation of cost data appropriate for anyone doing O&S life cycle cost analysis for current (and former) aircraft used in the US Air Force. The data includes military and civilian salaries, support costs by aircraft, and inflation indices. The use of these costs factors is mandated by the regulation to
comply with the CAIG requirements. The most important aspect of AFI 655-03 is that it contains a generic O&S cost model. The CORE cost model has seven major cost categories with up to four levels of indenture (i.e. 7.1.2.2.1 Officer), for a total of 93 entries. The main levels are: Unit Mission Personnel, Unit Level Consumption, Intermediate Maintenance (external to unit), Depot Maintenance, Contractor Support, Sustaining Support, and Indirect Support. The regulation is updated (at least) quarterly.

3.1.2 References 2 and 3 are the same document separated by three years, number 3 being the later of the two. This is an application of the standard modular life cycle cost model (MLCCM) to a hypervelocity vehicle. The vehicle can be manned or unmanned. The model was verified with shuttle data obtained from outside the contractor for the shuttle (congressional testimony, NASA documentation, etc.) and was found to predict the LCC of the shuttle relatively closely. This reference contains cost and manpower estimating relationships for R&D, production, and O&S life cycle cost for a hypervelocity vehicle. The model was designed to be run as a spreadsheet where the costs associated with each stage of the system is developed separately and then consolidated into a system summary of the life cycle costs over the life of the system. There are only minor revisions to the first document in the second.

3.1.3 Reference 4 documents the operation of the life cycle cost model developed in references 2 and 3 and is derived from reference 5. It explains how multiple stages (segments) of the vehicle can be costed separately using the appropriate CER or using actual cost data, if it is available, and then how the costs are to be accumulated in the appropriate subsystem. This accounting of costs complies with the guidelines of the CAIG. The program itself is implemented as a spreadsheet under LOTUS.

3.1.4 The modular life cycle cost model (MLCCM), reference 5, is the standard LCC model used by the US Air Force to comply with the CAIG directives. Most of the LCC models used in the Air Force are derived from this model. The model has more than 100 different data inputs and encompasses all phases of the life cycle (except disposal) of an avionic system life cycle. The model uses the type of material used in the different aircraft structures to determine the costs of materials, production, and repair based upon a comparison to standard aluminum practices. The shortcoming is the inability to predict disposal costs, but neither does any other appropriate LCC model.

3.1.5 Reference 6 is an attempt by NATO to develop a uniform method to estimate the life cycle cost of computer systems (software and hardware) used in C3I systems. This reference surveys the different types of models used in developing the cost estimates, which include PRICE-S, COCOMO, etc. The driver used in estimating the other output parameters (facilities, personnel, etc.) is lines of code (LOC). The different models use different methods in developing this simple parameter, depending upon which computer language is used and the complexity of the application. The more sophisticated models also use the size of computer, the application to be hosted, if hardware is to be developed and if it is to be developed in tandem with the software, and what level of experience the team creating the software/hardware has in similar projects. The costs are in international accounting units (IAUs) to reduce the bias
involved with selecting a particular monetary unit.

3.1.6 Reference 7 updates a Naval parametric Operating and Support estimating model using the CAIG guidelines for O&S cost analysis. The model updates 14 direct cost elements using 15 different aircraft types which represents the bulk of the Navy and Marine fixed-wing aircraft. Both linear and semi-log (log-linear) cost estimating relationships were developed for each of the direct cost elements. The presentation of the regression equations is the most complete of any of the models. The data points used, the residuals, outliers, and the fitting parameters are shown for each CER, this enables rapid verification of the CER or the development of different (exponential, etc.) relationships. The operational requirements and the maintenance philosophy used by the Navy prevents the direct application of many of the developed CER’s for use in this study. The completeness of the data analysis in developing the CER’s provides a basis of comparison between those developed for a space system and the CER’s developed from the NAVY data. This allows a validity check of the space developed CER’s by analogy with the NAVY CER’s. The NAVY CER’s can be used as a bound on CER’s developed for conceptual space systems.

3.1.7 Reference 8 is geared toward a transportation system to place man and/or material in space. The costs are for three different configurations of vehicle (winged, aerodynamic and ballistic) with different launch scenarios. The model can be implemented on a PC using a spreadsheet.

3.1.8 Reference 9 is a summary of the cost model used by the former Strategic Air Command (SAC) to do a high level estimation of the costs associated with the strategic nuclear missile fleet. This high level fast response model relies heavily on readily available information contained in AFI 655-03 (former AFR 173-13) as input to the model. This model will run on a simple PC-based spreadsheet.

3.1.9 Reference 10 is the USAF Space Division’s detailed analytic cost estimating relationships derived from eighteen unmanned space vehicles. The CER’s are derived from regressions equations encompassing recurring and nonrecurring costs across system phases. The system phases include research and development, and production of space hardware from the component level (when available) through final assembly including normal program costs (like overhead and G&A). Some systems have over 3000 account names which were then incorporated into larger systems. This costing system is organized to be implemented as a PC based spreadsheet.

3.1.10 The study identified in reference 11 is a detailed and comprehensive set of algorithms for estimating operations and support costs of Air Force aircraft systems. Referred to as the Model for estimating Aircraft Costs of Ownership (MACO), the study was completed in 1981 and used as a basis for developing cost relationships. The study used as primary sources of input: AFR 173-13, the Logistics Support Cost Model (LSC), the Logistics Composite Model (LCOM), and AFM 26-3 (Manpower Standards) as well as other models. Much of the organization level manpower was based on LCOM generated manpower obtained from tactical
fighter aircraft. There is also considerable detail on the costing of repairable spares which follows the Air Force's methodology for requirements determination. The study is a combination of new cost estimating relationships (CERs), accounting formulas, and some historical rates and percentages. The cost element structure used is consistent with the CAIG guidelines.

3.1.11 The Logistics Cost Analysis Model (which will be referred to as the Logistics Model) was developed in 1993 by Rockwell International at the request of NASA to review, modify and validate costing methodologies that apply to certain categories of logistics costs based upon the Shuttle program and other relevant military and commercial logistics operations. A key feature of this study is the identification of typical input parameter values needed to perform an accounting method of cost estimation. The completed model is available on an EXCEL spreadsheet.

3.1.12 The Reliability and Maintainability (RAM) model was developed by the University of Dayton in order to provide a parametric method for estimating the mean time between maintenance actions and removals as well as the mean time to repair failed components. This model was developed for use during the conceptual design of new space transportation systems. It was originally intended to provide input into a computer simulation model of the proposed space transportation systems. However, the model, using the estimated reliability and maintainability parameters, will provide estimates of organizational level manpower, initial spares, removal rates, and vehicle turn times which can be used in determining support costs. Use of the output of this model for costing provides a direct relationship between design and performance trade-off which impact on reliability and maintainability and the subsequent operations and support costs.
3.2 Application to the NASA Cost Element Structure

Although the cost element structure utilized in this study is the linear one presented in Table 2-1, there is a second dimension to the costing which must be considered. The second dimension is that of time. A typical project will go through a predictable life cycle, as shown in Figure 2-1. Initially the project will be in Research and Development (including testing and evaluation), Production, Operation and Support (including spares), and Disposal. A life cycle cost is the total dollar value of the resources (material, labor, etc.) that the project will consume from its inception to its ultimate disposal. The two-dimensional view of the life cycle costs is shown in Table 3-1. In computing operational and support costs, the economic life of the system is assumed to begin at its initial beddown year. Prior years in which conceptual development and acquisition costs were incurred does not include the operations and support costs.

4.0 Methodology

4.1 General approach

The ultimate objective is the development of an automated life cycle costing model (LCCM) to be used during the conceptual design of a space transportation system. To meet this objective, the following steps were pursued:

4.1.1 The establishment of a Cost Element Structure (CES) useful in the development, implementation, and execution of the LCCM. The structure must be compatible with existing LCC methodologies, be acceptable to NASA, and provide the necessary level of detail to establish a reliable cost estimate. Section 2.0 documented the initial effort in the development of such a CES by identifying NASA's current CES (which is still under review) which was based, in part, on a comparative analysis of the cost element structures used by other LCC models. The CES documented in Section 2.0 formed the basis for the costing model presented in this section.

4.1.2 An analysis and summary of current costing models which may be adaptable in the space environment. These models were developed for use in costing aircraft, launch vehicle, and other space systems. The intent was to evaluate the costing methodology and resulting relationships in order to adapt these relationships, where appropriate, to the current study. The existing costing techniques were used to the extent possible. Section 3.0 summarizes those costing studies which were relevant and identifies those costing relations which were utilized.

4.1.3 The identification of those cost elements from the CES which were not appropriately addressed in existing studies. For the facilities cost elements, new cost data has been obtained and new cost relationships established. Since the hypervelocity cost model discussed in Section 3.0 required the use of vehicle design and performance variables not previously used in the RAM model, additional parametric equations were developed to estimate these values from a relatively small set of "driver" variables such as "dry weight", "length plus wing span", "crew size", and "number of main engines." These equations were identical in form to the "secondary variable" equations developed for use in the RAM model. Section 5.0 addresses both these additional secondary equations and the facilities cost relationships developed for direct use in the model.

4.1.4 The integration of new and existing cost element relationships (CER's) into the model in a logical and cohesive manner. This required selective adaptation and, in some cases, modification of existing CER's. In particular, input parameter data had to consist of those performance and design specifications which can be determined during the early conceptual design of the vehicles. Some parameters were estimated from knowledge of others using the parametric equations discussed above and output from the Reliability and Maintainability model using primarily dry weight (a measure of the size of the vehicle) as the independent variable. Different LCCM's also have utilized different costing base years, therefore, using inflation indices, these cost estimates had to be transformed to a common base year.
4.1.5 The development of a user-friendly computer model to implement the costing methodology. This model is compatible with the Reliability and Maintainability Model using both its input and output where appropriate to provide input to the O&S cost model. The computerized model has user friendly input of additional parameter values and provides several levels of output reports in support of the vehicle design studies. In particular, it should be suitable for performing trade and "what-if" studies.

4.2 Costing Relationships

The final costing model utilizes four different approaches in developing the cost estimates:

a. Cost Estimating Relationships (CERs)
b. Accounting techniques
c. Historical factors (analogy)
d. Direct cost input

Primary use is made of cost estimation relationships (CER) obtained by using multiple regression techniques to fit historical cost data to one or more vehicle design or performance variables. Parametric estimating methods provide a statistical basis for establishing a relationship between costs and one or more "cost-drivers." With the dependent variable being cost, independent variables such as weight, length, thrust, volume, quantities, etc. may be excellent "cost-drivers." Many of these CER's have been derived from aircraft data. To the extent the range of values of the independent variables encompass the space vehicle values, these relationships can be adopted for use in this study. Again, however, the independent variables must consist of those parameters which can be determined or estimated (perhaps themselves parametrically) in the early conceptual phase of the study. Some cost estimates are also based upon analogy using cost data obtained from the shuttle program. Adjustments may be made for difference in size, number of engines, performance, etc. For some subsystems and some functions (particularly in the area of operations) this approach may provide the only means for obtaining a cost estimate since the shuttle is the only vehicle of its type and purpose (a sample size of one).

Accounting techniques make use of direct input of rates and cost factors. Annual and life cycle costs based upon these factors are then computed by multiplying cost rates and quantities and then summing the resulting costs. For example, annual fuel cost (consumables) is obtained by multiplying the fuel requirements (in lbs) per mission by the number of missions per year by the unit cost of the fuel. These costs are summed across each propulsion system (e.g. main engines, OMS, RCS).

Historical factors are generally percentages or rates computed from past data. Examples include ILS management which is a percent of logistics cost elements and modification costs which are computed as a percent of the vehicle unit production cost (flyaway cost). In some cases these factors are based upon Shuttle data and in other cases they reflect an average aircraft environment value.
Finally, in some cases direct costs may be used. This is true for those operational categories in which the shuttle program may provide the only source of data. The primary costing method utilized is CERs with analogy from the space shuttle as a secondary costing method.

Table 4-1 summarizes the methodology used in deriving costs estimates for each of the support cost elements addressed in this study.

4.3 Inflation Adjustments

Since various cost models have differing historical base years, an inflation adjustment had to be made to bring the costs to an initial 1993 base year. This adjustment was based upon NASA's Code B inflation rate indices providing actual (historical) inflation factors. The basic calculation is:

\[
COST_{93} = (\text{inflation factor}) \times COST_{yr} 
\]

A further calculation is then made to adjust the cost to the base year identified by the user (assuming it is different from 1993) where f' is the geometric average annual inflation factor for the period from 1993 to the base year. This factor is calculated from the NASA inflation rate index (future). The final cost is then given by:

\[
COST_{\text{base yr}} = COST_{93} \times (1+f')^{\text{base yr}-93} 
\]

This cost is then applied to both nonrecurring and recurring costs over the life of the system in order to obtain constant dollars at the base year.

In order to obtain actual (i.e. then year) dollars for year t, the following additional calculation is performed:

\[
COST_{yr \ t} = COST_{\text{base yr}} \times (1+f')^{\text{base yr}-\text{yr}} 
\]

Total life cycle costs may also be computed in two ways: (1) constant base year dollars or (2) then year (inflated) dollars. For constant base year dollars the recurring costs inflated to the base year are multiplied by the system life. For then year calculations, the following formula is used:

\[
LCC = \left[ \frac{(1+f')^n-1}{i} \right] \times (\text{annual recurring cost}) + \text{nonrecurring costs} 
\]

where f' is the geometric mean inflation rate over the beddown life of the system and n is the number of years of system life. Both the recurring and nonrecurring costs are inflated to the beddown year. The only exception to this calculation is Program Phaseout which is reflected as a single annual cost inflated to the last year of the system life.
5.0 Parametric Equation Development

5.1 Facility Operating and Maintenance Costs

Identification of facility requirements necessary to support systems that are in the conceptual design phase is, at best, difficult. Specific requirements of the system concerning the design, operational concepts and maintenance concepts have not been finalized. Additionally, areas such as support equipment development, spares requirements, or maintenance procedures in many cases have not been thought of yet or at best they are in their design infancy. In all likelihood, the design or procedures will change as the system develops and ultimately have a significant impact of the facility requirements needed to support the system. This section provides a methodology that can be used by space systems planners to estimate the gross facility requirements so that an initial life cycle cost can be derived for the proposed conceptual space system. This methodology will not consider facilities that are unique to an operational or maintenance feature of a specific system. These facilities (e.g., composite repair, heat absorbent material repair, etc.) will have to be identified and costed separately based on the information available concerning the facility. However, the methodology developed as a result of this research effort will provide a means to estimate the general facility requirements of a system. Parametric equations for facility square footage will be developed from data applicable to a wide range of aircraft currently in the United States Air Force inventory. Table 5.1, Study Aircraft (USAF), lists the US Air Force aircraft that were used in this study. The assumption here, is that future space systems will be aircraft like and use operational and maintenance procedures similar to those used in the United States Air Force and commercial aircraft industry. The effort included a review of the procedures established by the Aeronautical System Center, Directorate of Systems Facility Engineering, Wright-Patterson AFB, Ohio, for identification of facilities required to support bed down of new aircraft weapon systems. The Advanced Manned Launch System study provided the following information of the facilities required to support a space transportation system. The study summarized five major facility areas--landing site, horizontal processing facility, payload containment system processing

Table 5.1 Study Aircraft (USAF)
facility, launch pad and launch/mission control center.

Landing Site. The landing site will be used for arrival of orbiter and booster elements at the launch site. The vehicles will arrive either from the manufacturer on a carrier aircraft such as the Boeing 747, or as part of recovery of the orbiter and boosters upon completion of a mission.

Horizontal Processing Facility. The Horizontal Processing Facility will consist of three areas--processing bays, mating bays, and storage bays. Vehicles will be processed in a horizontal position similar to commercial aircraft to decrease the facility height, decrease operational complexity, and permit ease of access to the vehicle elements. The overall impact of these decisions will be a reduction in the initial cost of the facility--using more standard construction techniques--reduce facility operating costs, as well as, the overall operating cost of the system.

Payload Containment System Processing Facility. The Payload Containment System Processing Facility consists of a single facility capable of performing minimal checkout and verification of the orbiter and its payload.

Launch Pad. The pad will have a minimal tower structure with few umbilical connections to the vehicle. The tower structure will provide access to the crew module and payload containment system.

Launch/Mission Control Center. The control center will allow for the integration of data from all aspects of the vehicle operations. Training resources, flight operations and launch control would reside within this one common complex.

The support concepts represent a major change in the maintenance philosophy away from the concept currently used to support space vehicles toward one more similar to that of an aircraft where one-time certification with constant maintenance to ensure air worthiness of the vehicle is the normal certification and maintenance procedure for aircraft. The maintenance would be performed by airframe and propulsion technicians as is currently the practice in the commercial airline industry. The various airframe and propulsion skills that would be necessary to perform maintenance include: Structural, Thermal Protection Systems, Helium Purge, Landing Gear and Auxiliary Systems, Main Propulsion, Prime Power, Electrical Conversion and Distribution, Surface Control Actuators, Avionics, Environmental Control, Personnel Provisions. Each of these skills in turn would require facility space to perform the maintenance required on the system.

---

1 "Advanced Manned Launch System Study (AMLS), Interim Review, Rockwell International, June 1991"
A review of current United States Air Force standard facility requirements, as well as, procedures used by the Aeronautical Systems Center to identify facilities to support bed down of aeronautical systems resulted the list of general operational and maintenance facilities shown in Table 5.2, General Operational and Maintenance Facilities.

Table 5.4 Facility/Skill Comparison

A comparison reveals that facilities similar to those supporting United States Air Force aircraft will be required to support conceptual space vehicles using comparable maintenance concepts.

5.2 Estimation of O&S Costs

In this analysis, multiple regression techniques were used to determine parametric relationships for operations and support cost per aircraft as a function of various design, performance, and weight data. Historical operations and support cost were analyzed in an effort to develop general cost estimating relationships that could be used in estimating the facility operations and support costs. The following dependent facility variables were determined using regression analysis: Material Costs, contract costs, personnel costs, and other costs measured in dollars per aircraft.
Table 5.5 identifies the independent variables and the range of the variable used in this analysis.

Table 5-5, Independent Variables
Facility operation and support cost ($ per aircraft) parametric estimating relationships were developed to estimate the yearly cost to operate, repair and maintain the facilities necessary to support the anticipated operational and support concepts of a conceptual space vehicles or systems. The objective for providing these equations is to provide space system planners with a means to identify an initial "ball park" estimate of the facility operation and support cost requirements that will form the basis for performing initial facility life cycle costing on the proposed space system.

The operations and support cost data was obtained from the Visibility and Management of Operating and Support Cost (VAMOSC) System. The costs included those allocated to the personnel assigned to the maintenance and operation of real property facilities and related management and engineering support work and services. The costs also include those associated with materials, contract and other expenses associated with maintenance of real property facility assets. The cost data used to develop the parametric cost estimating relationships was the total yearly aggregated cost for a specific weapon system and mission design series ($ per year and aircraft type). No relationship exists between operation and support cost parametric estimating equations and the size and type of facility. The cost of a specific type of facility type ($ per square foot) could not be obtained for use in the development of the operation and support cost parametric estimating equations.

The operating and support cost parametric estimating equations (Table 5.6) are derived from fiscal year 1989 operation and support cost for the twelve specific aircraft identified in Table 5.1, Study Aircraft (USAF). Four specific cost areas were identified in the Visibility and Management Operating and Support Cost database and they included material, contract, other and personnel costs needed to maintain and repair the facilities necessary to support the mission of the aircraft selected.

Material Costs: This data includes all costs expensed for materials associated with the repair and maintenance of real property facilities identified by specific command and geographical location codes (OAC/OBAN codes). The costs must also carry a PEC code of XXX94 for real property maintenance cost expenses with Element of Expense Investment Code of 60XXX through 63XXX.

Contract Costs: This data includes all costs associated with real property facility maintenance that was completed by contract and are identified by specific command and geographical location codes (OAC/OBAN codes). These costs must also carry a PEC code of XXX94 for real property maintenance cost expenses with Element of Expense Investment Code of 51XXX through 59XXX.

Other Costs: This data includes all remaining Element of Expense Investment Codes associated with real property facility maintenance within PEC code XXX94.

Personnel Costs: This data includes all costs allocated to personnel assigned to the maintenance, repair, and operation of real property facilities and related management and engineering support work and services.

5.3 Secondary Variable Equations

In order to provide a means of assigning values to many of the independent variables required by the various LCC models, regression equations were developed using the same aircraft data set which was used in the RAM study. The following equations were derived and are consistent with the development and use of the "secondary variable" equations used in the RAM model.

The detailed regression reports may be found in Appendix B. These equations are evaluated based upon values assigned to the independent variables from the RAM model. Therefore, any changes in those variables from the reliability analysis will have an impact on the cost model.

5-8
6.0 Support Cost Model

Following the cost element structure described in Section 2.0 and using the LCC models described in Section 3.0, the following cost equations were selected, updated, and implemented into the overall support cost model. The variable definitions may be found in Appendix C and the costing equations are summarized in Appendix D. The following discussion pertains to cost elements 2.3.2 Maintenance, 2.3.3 Logistics, and 2.3.4 System Support. Equations based upon the Logistics Cost Analysis Model are not discussed in detail here since they are adequately presented in the Rockwell study (reference 48) and are being independently evaluated by NASA.

6.1 Refurbishment (CES 2.3.2.1)

The only source of a cost estimating equation was the Prevail model. Since the Prevail model consists of algorithms for the conceptual design of space transportation systems, the cost relationships developed were based in part on Shuttle cost data. Prevail defines refurbishment as a function of those subsystems which must be repaired (refurbished) or replaced and the cost of sustaining engineering for refurbishment items. The assumption is that this task is consistent with NASA's definition of refurbishment which is the restoration of the system from conditions exceeding normal wear and tear. Cost is a function of two elements:

\[
\text{Total Refurb Cost} = \text{refurb of vehicle} + \text{refurb of engines}
\]

where

\[
\text{refurb of vehicle} = .02 \times \text{avg cost of production stage (AVST) ($M)} + .05 \times \text{sustaining engineering costs (SE) ($M)} \text{ for refurbished subsystems}
\]

and

\[
\text{refurb of engines} = .1 \times \text{nbr of engines (NOENG)} \times \text{avg cost of production engine (AVCE) ($M)} + .1 \times \text{sustaining engineering cost for refurbished engines (SENG) ($M)}
\]

Production costs should be obtained from the acquisition costs (CES 2.2.2) while sustaining engineering costs must currently be estimated. Both costs currently require direct input into the model. Prevail provides a methodology for estimating sustaining engineering costs, however, to implement this methodology, the Prevail CER's for production costs must also be implemented.

6.2 Organizational Maintenance (CES 2.3.2.2)

Organizational maintenance costs consists of three cost elements: (1) direct labor maintenance personnel, (2) maintenance overhead, and (3) maintenance material. Direct labor maintenance personnel costs are determined directly from the total personnel required as computed by the RAM model. This includes both unscheduled and scheduled manpower based upon the maximum of the total manhours of work generated by workcenter or the minimum crew
size by workcenter. This number is then converted into a direct labor cost as follows:

direct labor cost = avg technician salary ($/hr) x 40 x 52 x manpower (from RAM)

Maintenance overhead costs are based upon the MACO model using the following CERs which provide manhours per month:

<table>
<thead>
<tr>
<th>Function</th>
<th>Equation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Chief of Maintenance</td>
<td>$2125.6 + .5032 \times \text{msn hrs per month}$</td>
</tr>
<tr>
<td>Quality Control</td>
<td>$3477.2 + .7469 \times \text{msn per month}$</td>
</tr>
<tr>
<td>Maintenance Control</td>
<td>475.397</td>
</tr>
<tr>
<td>Job Control</td>
<td>$1082.7 + 1.143 \times \text{msn hrs per month}$</td>
</tr>
<tr>
<td>Plan &amp; Scheduling</td>
<td>$532.8 + 1.0813 \times \text{msn per month}$</td>
</tr>
<tr>
<td>Documentation</td>
<td>264.2 + 6.393 \times \text{nbr of vehicles}$</td>
</tr>
<tr>
<td>Material Control</td>
<td>$19.18 \times \text{(msn per month)}^{0.4269}$</td>
</tr>
<tr>
<td>Supply Liaison</td>
<td>$505.8 + 1.013 \times \text{msn per month}$</td>
</tr>
<tr>
<td>Production Control</td>
<td>$713.7 + .9658 \times \text{msn per month}$</td>
</tr>
</tbody>
</table>

Total monthly hours are computed and then divided (and rounded up) by the monthly manhours available per person from the RAM model (default = 144 hours). These numbers are then converted to costs using the same calculation as direct labor.

The material costs (hardware) are based upon the HVL model which provides separate CERs for organizational level maintenance material and depot level maintenance material (both of which are separate from initial and replenishment spares). The regression equations shown provide dollars per flight and are then multiplied by the number of flights per year to obtain a total annual recurring cost.

6-2
ECLS  \[252.16 \times \text{hours per msn}^{5813} \times \text{Fuselage vol}^{46728}\]

Flight Provisions  \[11.5099 \times \text{cargo vol}^{42602} \times \text{hours per msn}^{77562}\]

Docking  \[.0749785 \times \text{cargo weight}^{5375} \times \text{takeoff weight}^{40765}\]

The variable util rate is the number of mission hours per year per vehicle and is computed from the number of vehicles, the hours per mission, and the number of missions per year.

6.3 Depot Maintenance (CES 2.3.2.3)

Depot maintenance consists of two cost elements: (1) personnel and (2) material. Both of these are computed using the HVL CER's which may be found in Appendix D. The primary driver variables are the vehicle design and performance variables obtained from the RAM model, or, in a few instances, input directly by the user. These equations provide dollars per flight and are then multiplied by the number of flights per year. All dollars are FY 1980 and are adjusted to an FY 1993 value.

6.4 Modifications (CES 2.3.2.4)

This cost element is based upon a historical factor found in the MACO model. The modification costs are obtained by taking \(.004494 \times \text{unit production costs (flyaway cost)} \times \text{number of vehicles in the fleet in year t}\). The number of vehicles in a given year is assumed to be constant in the initial implementation of this model. Therefore, the factor is currently multiplied by the production costs (CES 2.2.2) to arrive at an annual modification cost. It is then treated as a recurring cost.

6.5 Spares (CES 2.3.3.1)

There are two alternative methods for estimating spares cost. One is based upon the HVL model CER's for both initial and replenishment spares. The other is based upon the Logistics Cost Analysis Model (LOG). The HVL cost equations use the design and performance variables as input and computes dollars per flight for each of the nine WBS categories shown above under the organizational maintenance costs. The 18 equations (shown in Appendix D) are then multiplied by the number of flights per year and summed.

The LOG model is based upon the Rockwell study and output from the RAM model. Initial spares costs are computed from the number of spare LRU's generated from the RAM model (rather than the sufficiency formula shown in the Rockwell study) multiplied by an adjusted average dollar cost per LRU. Replenishment spares are computed from:

removals per flt (from the RAM model) \(\times\) flight/yr \(\times\) condemnation rate \(\times\) avg LRU cost
This cost may be further adjusted by a commonality factor.

6.6 Expendables (CES 2.3.3.2)

Expendables are items which are expended on a per flight basis. While NASA treats the external tank as an expendable item, the military has traditional considered expendables to be the non-repairable items used in maintaining components. Items such as transistors, nuts and bolts, circuit boards, cable, etc. are computed using economic order quantity models (EOQ) and are therefore sometimes referred to as EOQ items. This is the category of items which are currently being costed. The MACO model provides the only source for costing this type of expendables. A modified equation from the MACO model resulted in:

$$\text{EOQ } \$ = -29.9 + .039 \times \text{removals/flight} \times \text{flights/yr} \times (1-\text{condemn rate}) \times \text{avg LRU cost.}$$

6.7 Consumables (CES 2.3.3.3)

The LOG model provides an accounting formula for computing consumables consisting of fuel, oxidizer, and ECLSS costs. Fuel and oxidizer costs are based upon consumption in lbs per flight x the number of flights per year x $ cost per lb while life support system costs are computed from:

$$\text{crew size} \times \text{ECLSS } \$ \text{ cost/2 person days} \times \text{mission hrs/48} \times \text{flight/yr}$$

Consumption rates and cost factors must be input directly. Both a recurring and nonrecurring cost is computed.

6.8 Inventory Management and Warehouse (CES 2.3.3.4)

Again the LOG model is the basis for computing this cost element. This cost is primary the cost of obtaining and maintaining supplies to support the missions. The LOG model computes both a recurring and nonrecurring cost. The nonrecurring cost is based upon the number of spares LRUs and the number of components per LRU giving a total inventory level which is then multiplied by an initial warehouse manhour value and a logistics salary in dollars per hour. The recurring cost is a multiplicative factor (recurring inventory factor) of the total number of recurring and nonrecurring spares. The implementation of this methodology resulted in computing recurring costs in the same manner as nonrecurring costs. That is,

$$\text{recur costs} = \text{removals/flt} \times \text{condemnation rate} \times \text{flights/yr} \times \text{avg nbr of components/LRU} \times \text{init warehouse mhrs} \times \text{logistics salary}$$

6-4
6.9 Training (CES 2.3.3.5)

Training includes both organizational and depot level and both nonrecurring and recurring cost categories. The LOG model provides the cost equations which requires course times, course costs, number of technicians, technician turnover rate (for nonrecurring costs) and technician salaries as input. The equations are listed in Appendix D.

6.10 Documentation (CES 2.3.3.6)

Both the LOG model and the HVL model provide a costing methodology for documentation (data in HVL). HVL is broken into the nine WBS categories and provides only recurring costs in dollars per flight based upon vehicle design and performance variables. The LOG model computes both recurring and nonrecurring costs using an estimate for maintenance significant items, tech manual page counts, tech manual page costs, and other factors. The equations are listed in Appendix D.

6.11 Transportation (CES 2.3.3.7)

Addressed only in the LOG model, transportation costs are computed by:

\[
\text{nonrec: } \# \text{ vehicles} \times \text{dry weight} \times \text{packaging weight tax} \times \text{distance} \times \text{transporter $/lb-mi}
\]

\[
\text{rec: } \text{nonrec cost} + \text{removals/flt} \times \text{dry weight/# LRUs} \times \text{packaging wgt tax} \times \text{depot distance} \times \text{depot transporter $/lb-mi}
\]

All factors must be input directly.

6.12 Support Equipment (CES 2.3.3.8)

Both the HVL and LOG models provide equations for both recurring and nonrecurring support equipment costs. The LOG model equations are in Appendix D and are functions of the vehicle size (dry weight) launch rate, number of vehicles, and vehicle turnaround times. It is a proration of a shuttle based vehicle GSE cost and DSE (Depot support equipment).

The HVL equations for nonrecurring costs in dollars are given below:

<table>
<thead>
<tr>
<th>WBS</th>
<th>EQUATION</th>
</tr>
</thead>
<tbody>
<tr>
<td>Structure</td>
<td>644.063 \times \text{fus vol}^{70593}</td>
</tr>
<tr>
<td>Landing Gear</td>
<td>.306413 \times \text{takeoff weight}^{70378} \times \text{maxmach nhr}^{11614}</td>
</tr>
</tbody>
</table>
Payload Deply/ret \( \cdot 02 \) x unit production cost

Avionics \( 376.149 \) x avionics install wgt\(^{1.1071}\)

Electrical \( 20536 \) x Max KVA\(^{1.8723}\) x Maxmach nbr\(^{87839}\)

Hydraulics \( 2400.88 \) x nbr hydr subsys\(^{76158}\)

ECLS \( 7812.31 \) x nbr seats\(^{78097}\) x maxmach nbr\(^{9731}\)

Flight Provisions \( 3.059 \times 10^9 \) x tot thrust\(^{1.8319}\)

Docking \( \cdot 795139 \) x fus volume\(^{70503}\)

For recurring costs, the cost (dollars) per flight is \( \cdot 2 \) x nonrecurring cost.

6.13 ILS Management (CES 2.3.3.9)

The LOG model determines an ILS management cost as a fixed percent of the sum of all other logistics cost elements. This is done for both recurring and nonrecurring costs. These factors are currently \( \cdot 08 \) for nonrecurring costs, and \( \cdot 13 \) for recurring costs.

6.14 Support Staff (CES 2.3.4.1)

Staff consists of administrative and engineering. The HVL model provides the following costing methodology for the administrative costs by first computing aircrew and command staff costs.

\[
\begin{align*}
\text{aircrew } \$ \text{ cost} &= \cdot 21458 \times \text{crew size}^{1.6422} \times \text{nbr of vehicles}^{89681} \\
\text{comd staff } \$ \text{ cost} &= \cdot 21458 \times \text{util rate}^{50621} \times \text{nbr of vehicles}^{89225} \\
\text{admin staff } \$ \text{ cost} &= \cdot 2 \times (\text{aircrew } \$ + \text{comd staff } \$)
\end{align*}
\]

The Prevail model provides a historical factor for computing an engineering support cost which is 5 percent of the launch, flight, and recovery operations (i.e. CES 2.3.1). Recurring costs for support staff is then computed from:

\[
\text{support staff } \$ = \text{admin staff } \$ + \cdot 05 \times \text{annual operations costs } \$
\]

6.15 Facilities operations and maintenance costs (CES 2.3.4.2)
These recurring annual costs are computed from the CERs identified and discussed in Section 5.0.

6.16 Communication (CES 2.3.4.3)

Communications costs are estimated from an installation support cost equation found in the MACO model. Installation support costs include communications, civil engineering, supply services, personnel services, security, transportation, financial services, and other base support activities. The communications cost is a one-sixth proration of the total installation support cost as computed in Section 6.17.

\[
\text{comm} \; \$ = \frac{\text{installation spt} \; \$}{6}
\]

6.17 Base Operations (CES 2.3.4.4)

This cost category includes various base support functions such as security, fire protection, weather, legal services, personnel services, base transportation, accounting and finance, and etc. The MACO computes a personnel cost and then a material cost based upon a historical factor:

\[
\text{personnel cost} \; \$ = 0.156 \times 40 \times 52 \times \$/\text{hr technician salary} \times \text{nbr of mission personnel}
\]

Primary mission personnel is defined to be the total number of aircrews + command staff + maintenance personnel assigned at the base level directly supporting the mission activity.

\[
\text{hardware cost} \; \$ = 1920.77 \times \text{nbr of mission personnel}.
\]

Then

\[
\text{Installation spt} \; \$ = \text{personnel cost} \; \$ + \text{hardware cost} \; \$
\]

Since this cost includes facility costs (civil engineering) and communications which are addressed under separate cost elements, then

\[
\text{base operations} \; \$ = \frac{4 \times \text{installation spt} \; \$}{6}
\]

The prorations are arbitrary, and a further analysis of historical cost data is necessary to obtain more valid percentages.

6.18 Pre and Post launch cleanup (CES 2.3.4.5)

This function is normally performed by the civil engineering squadron on an airbase with some support from the aircraft maintenance manpower (as indirect work). Therefore, its cost is assumed to be included in the facilities O&M costs (CES 2.3.4.2).
7.0 Computer Implementation

The equations presented in Section 6.0 and in Appendix D are implemented in PC based model written in compiled BASIC for execution on any DOS computer. This model is compatible with the RAM model and will read directly a data file created by the RAM model. The model is menu driven allowing for easy file maintenance and update of input values.

The program is executed by typing LCC at the DOS prompt (or alternately the model could be loaded via Microsoft windows). The program will request a vehicle/file name. The name assigned should be the same name used in RAM model since the RAM model will produce an output file called "name".CST for use in the LCC model. Input values will be saved and subsequently read in by the LCC model from a file called "name".INP. Therefore the "name" assigned will be part of the file name for three different files each having a different extension (RAM saves its data in a file called "name".DAT).

After assigning a name, the main menu appears as follows:

```
LIFE CYCLE COST MODEL
VEHICLE IS TEST
MAIN MENU

OPTION NBR
INPUT FROM RAM MODEL..............1
GO TO INPUT MENU................2
DISPLAY RESULTS..................3
REPORT GENERATOR................4
SAVE INPUT VALUES...............5
READ INPUT DATA FROM FILE.......6
CHANGE VEHICLE/FILE NAME.......7
TERMINATE SESSION..............8
```

Normal use of the model would require the user to read in the "name".CST file from the RAM model. This in turn will update several system parameters variables and many of the design and performance variables including the calculation of the additional secondary variable values computed by the regression equations in Section 5.0. The user should then go to the input menu

```
DATA INPUT MENU

CATEGORY NBR
SYSTEM PARAMETER TABLE........1
UPDATE WBS COSTING TABLE........2
COST FACTORS & RATES.............3
DESIGN/PERFORMANCE VARIABLES...4
MISC FACTORS.....................5
```

and systematically update the various input factors, costs, and parameters. The system parameter table contains general information for life cycle costing including the number of vehicles, mission lengths, flights per year, inflation factors, economic life of the system, and the base year for
costing. The WBS costing table lists the Cost Element Structure from Section 2.0. The user can then identify by cost element whether to compute a value or to default to a user supplied value. Since the equations only address the support costs, the other cost elements should be defaulted to or ignored (if the user is only interested in the support costs). The next table lists all the cost factor and rates. These values should reflect 1993 costs since the model will then inflate these costs from 1993 to the base year (or then year) identified by user. The design and performance variable table (used primarily by the HVL model) lists vehicle characteristics such as design weight, number of control surfaces, total wetted area, etc. Many of these values are obtained from the RAM model and should not be changed unless changed within the RAM model. This will insure compatibility between the two models. The last input table contains almost 40 miscellaneous variables used primarily by the LOG model. The default values are for the most part, those contained within the Rockwell study.

After updating the input tables, the user will return to the main menu and select "Display Result." The following options are available:

SCREEN DISPLAY SELECTION MENU

1.......... SUMMARY BY WBS
2.......... HYPERVELOCITY MODEL COSTS
3.......... FACILITY COSTS
4.......... LOGISTICS MODEL COSTS
5.......... ORG MANPOWER COSTS
6.......... SYSTEM SUPPORT COSTS

RETURN......MAIN MENU

The primary output screen is the "SUMMARY BY WBS." This shows the results of the costing model by CES combining both the computed and default values and summing these to the higher level costs. In those cases where both the HLV and the LOG model provide costs estimates, this display will reflect the choice the user made on the System Parameter Table (the default is the LOG model). This display shows an annual cost (which includes any nonrecurring support costs) and a life cycle cost. The remaining menu selections will provide a more detailed breakout of the costing performed by the HVL model, facility O&M equations, LOG model, organization manpower costs, and system support costs.

The user may select to have a hard copy listing of any of these reports by selecting "REPORT GENERATOR" from the main menu.

REPORT GENERATOR MENU

1.......... PRINT INPUT DATA
2.......... PRINT WBS SUMMARY REPORT
3.......... PRINT HYPERVELOCITY MODEL COSTS
4.......... PRINT LOGISTICS MODEL COSTS
5.......... PRINT ORG MANPOWER COSTS
6.......... PRINT FACILITIES COST
7.......... PRINT SYSTEM SUPPORT COST
8.......... PRINT TOTAL OUTPUT
9.......... PRINT TOTAL INPUT/OUTPUT
RETURN......main menu
8.0 Conclusion

The costing methodology identified in this study attempts to integrate the previous developed reliability and maintainability model with existing costing equations and algorithms. It also attempts to integrate the support costs with the other life cycle costs in order to provide the cost analyst with a complete analysis tool. Obviously, the cost elements for those categories not addressed in this study must be obtained from other cost relations and methodologies. This model was developed in a highly modularized fashion with the expectation that additional cost relations will be added later so that eventually this model will become a complete LCC. There has been very little opportunity to validate this implementation and to calibrate the input data. This needs to be done before the model can be used with any confidence.

Life Cycle Cost Model Summaries

MODEL: Avionics Laboratory Predictive Operations and Support (ALPOS) Cost Model

COMPUTER IMPLEMENTATION: CDC-6600 mainframe. Fortran IV

APPLICATION: parametric O&M cost estimate of avionics equipment

SOURCE OF DATA: regression of avionic equipment data

INCLUDES: 15 estimating equations derived from logistics, support, and cost parameters derived from 10 dependent and 20 independent variables

EXCLUDES:

STAGES: operation and maintenance

INPUTS: MMH/OH, MTBF, unit price, unit volume, weight, component type, BIT/FIT factor, number of SRUs per LRU, aircraft type, operating hours per month

WBS: not explicitly stated

SUBSYSTEMS: user input

MODEL: CORE (and ZCORE)

COMPUTER IMPLEMENTATION: PC based in BASIC

APPLICATION: constant year LCC estimation of O&S costs

SOURCE OF DATA: AFI 655-03 (former AFR 173-13)

INCLUDES: eight primary cost categories (Unit Mission Personnel, Unit-Level Consumption, Depot-level Maintenance, Sustaining Investment, Installation Support Personnel, Indirect Support Personnel, Depot Nonmaintenance, and Acquisition and Training), class IV modifications, contractor logistics support

EXCLUDES: factors below the system (aircraft) or subsystem (radar, APU, etc.) level are not covered, vary resource inputs (manpower, etc.), aircraft availability

STAGES: O&S

INPUTS: system operating parameters and characteristics

WBS: WUC structure

SUBSYSTEMS: WUC structure
MODEL: Frieman Analysis of Systems Technique (FAST-E)

COMPUTER IMPLEMENTATION: PRIME mainframe

APPLICATION: computerized parametric cost estimating model used primarily by the energy industry to estimate equipment and system costs

SOURCE OF DATA: regression of equipment and system parameters as they relate to cost

INCLUDES: technology maturity (electronic, electrical, heat, motion, mechanical control, containment and supportive components), design masses (energy conversion, design overhead, application, dimensional, and conditional), weight, size, economics of production, engineering,

EXCLUDES:

STAGES: engineering, production, and installation

INPUTS: characteristics (see INCLUDES) of the system or equipment under study

WBS: not applicable

SUBSYSTEMS:

MODEL: Hypervelocity Life Cycle Cost Model (HVLCCM)

COMPUTER IMPLEMENTATION: mainframe (Fortran 77) and PC (spreadsheet)

APPLICATION: conceptual military hypervelocity aircraft LCC model

SOURCE OF DATA: modification of MLLCM (cargo plane) based on shuttle data

INCLUDES: PHASES 3 and 14 systems and subsystems, direct and indirect costs, RDT&E (5 CERs), System and Support Investment (Production) (12 CERs), O&S (85 CERs)

EXCLUDES: final disposal

STAGES: 3 and summary

INPUTS: vehicle operational characteristics (fuselage volume, weight, etc.), materials used by subsystem structure, tooling, payload characteristics (volume, weight, etc), system parameters, life cycle, G&A percentage, profit, number of prototypes, production numbers

WBS: RDT&E, production, O&S

SUBSYSTEMS: structure, landing gear, docking, payload Deployment & Retrieval, main propulsion, orbiting maneuvering, RCS, avionics, electrical/mechanical power generation and distribution, hydraulics, ECLS, flight provision, engine installation
MODEL: Logistics Support Cost (LSC) Model

COMPUTER IMPLEMENTATION: PC based in Basic

APPLICATION: Operating and Support Cost model at the LRU/SRU level

SOURCE OF DATA: AFLCP 173-3 and AFR 173-13

INCLUDES: initial and replenishment spares, depot maintenance, second destination charges, condemnation spares and spares used to fill the logistics pipeline

EXCLUDES: connection of spare cost to aircraft availability and logistic system, preventive maintenance

STAGES: not typically used prior to Milestone III of a program. O&S costs

INPUTS: ASCII file input of SRU and LRU costs and characteristics, and avionic system characteristics (size, weight, flight hours, etc.).

WBS: three to four (some five) digit WUC structure

SUBSYSTEMS: most subsystems are included in this "accounting-type" model.

MODEL: Modular Life Cycle Cost Model (MLCCM) for Advanced Aircraft

COMPUTER IMPLEMENTATION: Mainframe (CYBER 750 and NOS2 O/S in FORTRAN), PC spreadsheet (LOTUS)

APPLICATION: military aircraft life cycle costing

SOURCE OF DATA: regression of USAF aircraft systems and subsystems

INCLUDES: 4 PHASES, 12 systems/subsystems, MIL and CIV personnel, materials, contract costs (G&A, overhead, profit)

EXCLUDES: final disposal

INPUTS: system operational parameters, and characteristics (ie. weight, length, fuel consumption, construction material, etc.) and costs if known

WBS: Phases: rdt&e, production, initial support, and O&S

SUBSYSTEMS: structures, crew system, landing gear, flight control, engines, ECS, electrical system, hyd/pneumatic system, fuel system, avionics, cargo handling(or armament)
**MODEL:** Naval Fixed-Wing Aircraft Operating and Support Cost-Estimating Model

**COMPUTER IMPLEMENTATION:** PC based spreadsheet (LOTUS)

**APPLICATION:** Naval Fixed-Wing Aircraft Operating and Support Parametric Cost Estimates

**SOURCE OF DATA:** regression (linear and log-linear) of current Navy aircraft cost data

**EXCLUDES:** emergency repair and support costs - regression equation did not provide significant results (low adjusted coefficient of determination ("goodness-of-fit")), modification procurement - unable to segregate costs for emergency versus non-emergency modification of aircraft

**STAGES:** O&S

**INPUTS:** personnel by job function (air or ground crew, maintenance, etc.), pay rates, flying hours, empty loaded, empty, airframe, and engine weight of aircraft, maximum aircraft speed at sea level, number of engines, maximum thrust per engine, cost of procurement of safety related items, POL costs, cost of first 100 aircraft, aircraft rework cost/yr, and unscheduled maintenance manhours per aircraft.

**WBS:** CAIG structure

**SUBSYSTEMS:** none

**MODEL:** PREVAIL

**REFERENCE:** PREVAIL Algorithms for Conceptual Design of Space Transportation Systems

**COMPUTER IMPLEMENTATION:** FORTRAN 77 on a MAINFRAME (CDC Cyber, VAX, IBM 3090) and IBM PC.

**APPLICATION:** Sizing and cost of launch and orbital transfer vehicles

**SOURCE OF DATA:** Centaur, IUS, Titan III, STS (Shuttle)

**INCLUDES:** Subsystem (15) CER's for three primary cost categories: Design Engineering, Test and Evaluation, and Production for LO2-LH2 motors, solid rocket motor, winged stages and whether the stages are manned or reusable.

**EXCLUDES:** Cost for ground equipment, facilities, military pay, sharing of common subsystems, horizontal launch.

**STAGES:** reusable or expendable liquid oxygen, liquid hydrogen, solid rocket motor, liquid fuels, winged or manned stages.

**INPUTS:** vehicle/subsystem parameters, launch parameters, payload parameters, orbital parameters

**WBS:** 15 primary systems/subsystems in three cost categories

**SUBSYSTEMS:** structures, thermal, reentry protection, landing system, electrical-power, electrical-wiring, guidance&control, data handling, instrumentation, communications, propulsions systems, engine(s), RCS, interstage adapter, payload fairing.
MODEL: Programmed Review of Information for Costing and Evaluation (PRICE)

COMPUTER IMPLEMENTATION: mainframe

APPLICATION: life cycle costing of electro-mechanical hardware assemblies and systems

SOURCE OF DATA: RCA - purchase of network time

INCLUDES: design, drafting, project management, documentation, sustaining engineering, special tooling and test equipment, government furnished or modified equipment, material, labor, testing, and overhead

EXCLUDES: non-hardware costs of field test, site construction, and software

STAGES: development, production, purchase

INPUTS: quantity of equipment, schedule, hardware geometry (size, weight, etc.), complexity, operational environment, fabrication process, fixed and variable costs of material, facilities, and labor, and technology improvement

WBS: none implicit in the model

SUBSYSTEMS: none implicit in the model

MODEL: Reliability, Maintainability and Cost Model (RMCM)

APPLICATION: weapons system and support equipment's life cycle costs used to conduct requirements, costs, and trade-off analyses

SOURCE OF DATA:

INCLUDES: recurring, nonrecurring, and disposal costs

EXCLUDES:

STAGES: conceptual, development, production, and operation and support

INPUTS: reliability and maintainability of subsystems, unit costs, number of units procured, depot repair cycle time, etc.

WBS: three to four digit level of the WUC structure

SUBSYSTEMS: at the LRU level (see WBS)
MODEL: TI-59 Handheld Calculator Aircraft Top Level Life Cycle Cost Model (TI-59 ATL²C²)

COMPUTER IMPLEMENTATION: TI-59 Handheld Calculator

APPLICATION: flyaway cost of quantity 750 aircraft

SOURCE OF DATA: LSC model

INCLUDES: 42 inputs (30 default)

EXCLUDES:

STAGES: RDT&E, Production, initial and recurring O&S

INPUTS: required: empty weight, material of airframe % (3), rated thrust of engine (military-uninstalled, 30 minutes), number of engines, avionics weight per aircraft

WBS: none specified by model

SUBSYSTEMS: none specified by model

MODEL: Unmanned Space Cost Model 6 (USCM6)

COMPUTER IMPLEMENTATION: PC - LOTUS spreadsheet

APPLICATION: CERs for estimating hardware costs of earth-orbiting space vehicles

SOURCE OF DATA: regression of historic earth-orbiting space vehicles (18 programs)

INCLUDES: recurring and nonrecurring costs for: Payload (mission equipment), Spacecraft, Aerospace Ground Equipment, Launch & Orbital Operation Support, Integration and Assembly, Program Level, Dispenser (including structure), Structures & Interstages, ACS, Thermal Control, EPS, Telemetry, Tracking and Command (TT&C), Apogee Kick Motor (AKM) (propulsion), and Communications

EXCLUDES: Ground C³, Launch Vehicle, Sensors, Cameras, and Other Payloads

STAGES: Purchase of the hardware

INPUTS: Structure, Apogee Kick Motor (AKM), and Altitude Control System weight, Space vehicle weight, electrical power weight, power required, AKM impulse and stabilization, mission equipment weight, number of solar cells, communications subsystem weight, number of altitude sensors and weight, RF power output, receiver/exciter design life, weight of subsystems. G&A costs, profit, and number of vehicles

WBS: I. Space Vehicle, A) Integration and Assembly, B) Spacecraft, 1. structure, interstage/adapter, dispenser, 2. altitude control system, 3. thermal control, 4. electrical power supply, 5. telemetry, tracking & command, 6. apogee kick motor, C) Communications Payload, D) Program Level - program management, systems engineering, systems test and evaluation, data, II. Aerospace Ground Equipment, III. Launch & Orbital Operations Support

SUBSYSTEMS: see INCLUDES
MODEL: Model for estimating Aircraft Cost of Ownership (MACO)

COMPUTER IMPLEMENTATION: none identified

APPLICATION: Parametric O&M cost estimates of base and depot level maintenance manpower (including overhead). Accounting type equations for estimating scheduled maintenance manpower requirements and spares requirements. CER estimate for expendable (EOQ) items. Accounting approach used for support equipment, aircrews, wing/base support manpower, and training. Some historical factors developed for computing modifications and installation support hardware (material).

SOURCE OF DATA: Tactical Air Command LCOM studies, AFR 173-13. For the accounting type calculations, the user must supply the cost factors and rates. Air Force data systems are identified.

INCLUDES: Numerous CER's developed for base level maintenance manpower by workcenter. Also considerable detail on the calculation of reparable spares including jet engines.

EXCLUDES: Six cost elements in the CAIG structure: including facility costs, war readiness spares, some support equipment acquisition costs, documentation costs, and training equipment and services.

STAGES: operation and maintenance

INPUTS: Flying hours, sortie rates, number of aircraft, salary rates, component daily demand rates, base repair rates, repair cycle times, average flyaway cost, manpower productivity (manhours per month), condemnation rates, consumable unit costs, various manpower work standards, activity rates, and cost factors.

WBS: A mapping into the (1980) CAIG structure is provided.

SUBSYSTEMS: organization level manpower maps to the Air Force 2-digit WUCs

Appendix E

COSTING MODEL - SOURCE LISTING

Module Definitions:

LCC.BAS primary input file - contains main menu, initialization and data input

CST - cost parameter input/display
DATAIN - read in input data from a file
DRIVERS - design/performance variable input/display
INFA - inflation factor computations
INPT - contains input menu
MISC - miscellaneous factors input/display (LOG model)
RAMI - read in data from RAM model
SAVE - saves input data
SYS - system parameter table - input/display
WBSS - cost element structure input/display

LCC2.BAS computational file - evaluates all equations

COMP - main computational module for CES calculations
DRIVER - calls other computational modules in the proper order
FACILITY - computes facility O&S costs
ORG - computes organization maintenance personnel & hardware costs
OS - secondary calculations for HYP model
SECOND - evaluates regression equations for design/performance variables
TOT - performs a cost structure roll-up to the higher levels

LCC3.BAS - output file

DISMENU - displays output menu
DISMAN - displays organizational maintenance manpower results
DISWBS - generates primary output screen by CES
SPTC - displays system support costs
FACCOST - displays facility O&S costs
HYPDIS - displays hypervelocity model output in detail
LOGS - display logistics cost model output in detail
(plus corresponding print modules)

note: Several modules contained in the files and not listed above are currently not in use. They pertain to development and acquisition cost equations which are not being evaluated.
