Optimal Experimental Designs for the Estimation of Thermal Properties of Composite Materials

by

Deborah A. Moncman

Committee Chairman: Dr. Elaine P. Scott
Mechanical Engineering

(ABSTRACT)

Reliable estimation of thermal properties is extremely important in the utilization of new advanced materials, such as composite materials. The accuracy of these estimates can be increased if the experiments are designed carefully. The objectives of this study are to design optimal experiments to be used in the prediction of these thermal properties and to then utilize these designs in the development of an estimation procedure to determine the effective thermal properties (thermal conductivity and volumetric heat capacity).

The experiments were optimized by choosing experimental parameters that maximize the temperature derivatives with respect to all of the unknown thermal properties. This procedure has the effect of minimizing the confidence intervals of the resulting thermal property estimates. Both one-dimensional and two-dimensional experimental designs were optimized. A heat flux boundary condition is required in both analyses for the simultaneous estimation of the thermal properties. For the one-dimensional experiment, the parameters optimized were the heating time of the applied heat flux, the temperature sensor location, and the experimental time. In addition to these parameters, the optimal location of the heat flux was also determined for the two-
dimensional experiments.

Utilizing the optimal one-dimensional experiment, the effective thermal conductivity perpendicular to the fibers and the effective volumetric heat capacity were then estimated for an IM7-Bismaleimide composite material. The estimation procedure used is based on the minimization of a least squares function which incorporates both calculated and measured temperatures and allows for the parameters to be estimated simultaneously.
dimensional experiments.

Utilizing the optimal one-dimensional experiment, the effective thermal conductivity perpendicular to the fibers and the effective volumetric heat capacity were then estimated for an IM7-Bismaleimide composite material. The estimation procedure used is based on the minimization of a least squares function which incorporates both calculated and measured temperatures and allows for the parameters to be estimated simultaneously.

A composite material is composed of two or more materials joined together to form a new medium with properties superior to those of its individual constituents. There are many potential advantages of these materials including higher strength-to-weight ratios, better corrosion and wear resistance, and an increased service life over standard metals. Because of these improved characteristics, the use of composite materials has become quite extensive in the past twenty years, with the most widespread use being in the aerospace and aeronautic industries for the design of aircraft structural components. For example, composites are used in applications such as aircraft tail sections, wing skins, and brake linings. The F-111 horizontal stabilizer was the first flight-worthy composite component and in 1986, an all-composite airplane (the Voyager), set a world record in nonstop flight around the world, revealing amazing toughness and rigidity against harsh environmental conditions. However, the use of composites is not limited to the aerospace industry. Composite technology has also gained the attention of the automotive, tooling and sporting goods industries. Everything from car bodies and brake linings to tennis
rackets, golf clubs, bicycles, and fishing rods have been successfully manufactured from composite materials.

Composites are typically classified according to their reinforcement forms; these include particulate, fiber, laminar, flake, and filled/skeletal (Vinson and Sierakowski, 1987). Fiber-reinforced composites can be further classified as continuous or discontinuous. The major types of reinforcing fibers used in composites include glass, carbon/graphite, organic, boron, silicon carbide and ceramic fibers, while the major matrix resins consist of epoxy, polyimide, polyester, and thermoplastic, with epoxy resins being the most versatile of the commercially available matrices. The composite materials focused on in this study consist of continuous carbon fiber-epoxy matrix combinations.

With the increased use of composite materials in aerospace structures and other applications, it is important that the properties of these advanced materials be known for design purposes. Many studies on the mechanical properties of composites have been conducted; however, limited analyses have been made regarding the thermal properties. Knowledge of the thermal properties becomes important when the composite is subjected to a non-isothermal environment which creates thermal loads on the component. These thermal loads induce temperature variations within the structure, which in turn results in the development of thermal stresses and possible structural failure. In order to accurately predict these thermal stresses and prevent component damage, the temperature response of the structure must first be known. However, to determine this response, the thermal properties of the composite sample, which can be thermally or directionally dependent, are required. The prediction of these thermal properties has provided the motivation for
this study. This information will then aid designers in estimating thermal stresses existing in a structural component and in turn, allow them to prevent component failure.

1.1 Goals and Objectives

The main goal of this research is to predict the thermal properties of composite materials. This prediction requires temperature measurements, and therefore, experiments must be conducted. The overall objectives of this study are to

1) develop optimal experimental designs to be used in the prediction of these thermal properties

and

2) utilize these optimal designs in the development of an estimation procedure to determine the effective thermal properties, namely the thermal conductivity and volumetric heat capacity.

Optimal experiments were designed for both isotropic and anisotropic composite materials by selecting optimal experimental parameters that maximize the sensitivity of the temperature response with respect to changes in the unknown thermal properties. An isotropic material has identical properties in every direction while materials exhibiting directional characteristics are called anisotropic. For the anisotropic composite material, the effective thermal conductivity both parallel and perpendicular to the fiber axis direction can be estimated. This optimization procedure was performed because it increases the accuracy in the resulting thermal property estimates by minimizing the
confidence intervals of the estimated parameters.

The experimental designs that were optimized not only depend on the boundary conditions used, but also on what variability is permitted. An imposed heat flux at one boundary, resulting in conductive heat transfer through the composite sample, is required in the design to allow for the simultaneous estimation of the thermal properties. Therefore, optimal experimental parameters, such as the duration of the applied heat flux, should be determined. The optimal experimental parameters determined for the isotropic case include the heating time, sensor location, and experimental duration. For the anisotropic case, two different experimental designs were used. Both designs had a uniform heat flux applied over a portion of one boundary. However, this portion varied for the two configurations. Therefore, in addition to the parameters optimized for the one-dimensional case, the optimal position of the heat flux was also found in the two-dimensional analysis.

Utilizing the optimal experimental design determined for the isotropic composite material, the effective thermal conductivity perpendicular to the fiber axis and the effective volumetric heat capacity were then estimated for a composite consisting of continuous IM7 graphite fibers and a Bismaleimide (5260) epoxy matrix. Note that this is actually an anisotropic composite material; however, since the thermal conductivity is only estimated in one direction, this is equivalent to using an isotropic material. The estimation procedure used in this investigation was the Gauss linearization method and is based on the minimization of a least-squares function, containing experimental and calculated temperatures, with respect to the unknown thermal properties. This method not
only allows for the effective thermal conductivity and effective volumetric heat capacity to be estimated simultaneously, but also enables validation of the transient heat conduction equation.
Chapter 2

Literature Review

2.1 Determination of Thermal Properties of Composite Materials

This chapter summarizes the present state of knowledge pertaining to the estimation of thermal properties of composite materials. Due to their anisotropic nature, the estimation of the thermal properties of composites has proved to be a challenging task. This estimation problem is further complicated because a composite consists of at least two different materials, each with different thermal properties. Many methods, both experimental and analytical, have been proposed for estimating these properties with the thermal conductivity being most frequently estimated. In the following two sections, these estimation techniques are reviewed, describing the methods and procedures used. The experimental techniques utilized include both steady-state and transient heat conduction processes, while the analytical methods estimate the effective thermal properties using proposed mathematical models. These models assume prior knowledge of the thermal properties of the fiber and matrix themselves, along with the void fraction
of the fibers. The third section describes a minimization procedure based on the Gauss method used to estimate the thermal properties. The advantage of this procedure over previous techniques is that it allows thermal properties, such as thermal conductivity and volumetric heat capacity, to be estimated simultaneously. The thermal properties are found by minimizing an objective function containing calculated and measured temperatures. The last section discusses optimal experimental designs to be used with this minimization procedure which provide more accurate parameter estimates. Optimal experimental parameters to be used in these designs are found by maximizing the sensitivity of the temperature response with respect to changes in the thermal properties.

2.1.1 Experimental Determination of the Thermal Properties of Composite Materials

Experimental methods have been one of the main areas for determining the thermal properties of composite materials. These methods can be classified as either steady-state or transient. Ziebland (1977) described some steady-state experiments used to calculate the thermal conductivity that used both absolute measurements, where the thermal conductivity is determined directly from the measured quantities, and relative methods, in which the thermal conductivity is determined by reference to a substance of known thermal conductivity. The absolute methods are accurate but require expensive instrumentation and are generally time consuming and thus, expensive. One steady-state, absolute technique frequently used is the guarded hot-plate method. In this method, the specimen is heated by a hot metal plate attached to it and the resulting temperature is measured at the interface to estimate the thermal conductivity (Ziebland, 1977). Although
this method is quite accurate, substantial time is required to reach steady-state; therefore, the experiment is both expensive and time consuming.

Dickson (1973) has also described a simple steady-state method for measuring the thermal conductivity of insulation materials using heat flow sensors. This method requires the measurement of a heat flux and the temperature difference across a test specimen of known thickness. Penn, et al. (1986) extended this method to composite materials and developed a thermal conductivity measuring apparatus that uses heat flow sensors. This steady-state device used smaller sample sizes and as a result, reached thermal equilibrium in only a few hours. In addition, Harris, et al. (1982) used a two plate apparatus to experimentally determine the thermal conductivities of Kevlar 49 fibers in directions parallel and perpendicular to their lengths as functions of temperature, while Havis, et al. (1989) experimentally investigated the effect of fiber direction on the effective thermal conductivity of fibrous composite materials.

The evaluation of thermal conductivity from steady-state experiments is mathematically simple but frequently lengthy; it was for this reason that transient methods were developed. One transient method used to determine the thermal diffusivity, heat capacity, and thermal conductivity of materials is the laser-flash method which was first introduced by Parker, et al. (1961). In this method, the front face of a small sample is subjected to a short, radiant energy pulse. The resulting temperature rise on the rear surface of the sample is measured and the thermal diffusivity is then determined from the time required for the back surface to reach one half of the maximum temperature rise. This can be mathematically expressed as
\[ \alpha = \frac{KL^2}{t_{1/2}} \]  

where \( K \) is the constant corresponding to one-half of the maximum temperature rise, \( L \) is the sample thickness, and \( t_{1/2} \) is the time taken for the back surface to reach one-half of the maximum temperature rise. The heat capacity is found from the maximum temperature rise of the specimen, and the thermal conductivity is then calculated from the product of the thermal diffusivity, heat capacity, and density \((k = \alpha \rho c_p)\). The advantage of this technique over steady-state methods is that smaller sample sizes and shorter experimental durations could be used. Taylor, et al. (1985) studied the applicability of the laser-flash technique for measuring the thermal diffusivity of fiber-reinforced composites and found that the technique is appropriate for examining the transient heat flow in these materials.

Lee and Taylor (1975) used the laser-flash method along with an absolute method to directly measure the thermal diffusivity of graphite/carbon fiber in unidirectionally fiber-reinforced composites. The thermal diffusivity of graphite fiber-reinforced composites (Morganite II and Thronal 50 S) was also calculated from the effective thermal conductivity of composite samples measured by an absolute method. Taylor and Kelsic (1986) also used the laser-flash method to measure the thermal diffusivity of unidirectional fiber-reinforced composites. They then investigated the effects of the thermal conductivity ratio, fiber fraction, fiber orientation, and specimen length on the thermal diffusivity. Their results indicated that the fiber-matrix thermal conductivity ratio
was the major factor governing the thermal behavior followed by the fiber volume fraction. In addition, the thermal diffusivity of both silica and carbon fiber-phenolic resin composites was measured as a function of temperature using the laser-flash technique (Mottram and Taylor, 1987a). This work was extended (1987b) and the effective thermal conductivity parallel and perpendicular to the fiber axis was calculated using specific heat and density data.

The composite method was used by Brennan, et al. (1982) to measure the thermal conductivity and diffusivity of silicon carbide fibers. This method consists of measuring the thermal diffusivity of the composite and the matrix itself (without the fibers) using the laser-flash technique. From the definition of thermal diffusivity and the Rule-of-Mixtures (discussed in the next section), the thermal properties of the fiber can then be determined. It was found that the accuracy of the thermal conductivity values determined for the fibers could be increased by using a matrix material with a thermal conductivity as close as possible to that of the fibers. Furthermore, for this method to yield reliable data, it is essential that the scale of the microstructure and the size of the composite sample behave as a continuum in its transient response (Brennan, et al., 1982).

The laser-flash method also served as the basis for the techniques developed by Welsh, et al. (1987, 1990). In these studies, a pulsed heat flux was imposed on the surface of a material and the resulting thermal response at the same surface was then recorded. This method differs from the traditional laser-flash method in that the temperature response is observed at the heated surface rather than on the surface opposite to the flux. One disadvantage of this method is that the heat capacity and thermal
conductivity cannot be estimated independently, only the thermal diffusivity can be
determined.

In addition, Fukai, et al. (1991) also conducted transient experiments using a
periodic hot-wire heating method to simultaneously estimate the thermal conductivity and
diffusivity. In this method, the thermal conductivity and diffusivity were determined from
the amplitude and phase lag of the temperature response. The calculated properties agree
well with those measured by conventional methods. Beck and Al-Araji (1974) also used
a transient experiment to estimate thermal conductivity and volumetric heat capacity
independently.

2.1.2 Mathematical Determination of the Thermal Properties of Composite Materials

Mathematical models that are functions of the components of a composite have
also been used to determine the effective thermal properties, particularly thermal
conductivity. These models are based on the original theories by Maxwell and Rayleigh
(Hasselman and Johnson, 1987), with the effective properties being direct functions of the
thermal properties of the constituents, namely the fiber and the matrix. Therefore, it is
assumed that the thermal properties of the matrix and fiber are known, along with the
void fraction of the fibers. Typically, results of the mathematical model approach are
expressed as the ratio of the effective conductivity of the composite to the matrix
conductivity. This ratio depends on the ratio of the volume of the fiber to the total
volume and the fiber-matrix conductivity ratio (Han and Cosner, 1981). Hasselman
(1987) also found that if an interfacial thermal barrier resistance was present in a
composite system, the effective thermal conductivity not only depends on the volume fraction of the fibers but also on the fiber size.

One mathematical model, known as the Rule-of-Mixtures, to describe the effective thermal conductivity \( (k_{\text{eff}}) \) of a composite with heat flow parallel to the axis of the fiber is given by

\[
k_{\text{eff}} = k_f V_f + (1 - V_f) k_m
\]

(2.2)

where \( k_f \) is the thermal conductivity of the fibers, \( k_m \) is the thermal conductivity of the matrix, and \( V_f \) is the fiber volume fraction.

A unit-cell approach was presented by Ziebland (1977) to describe the thermal conductivity of a composite perpendicular to the fiber axis; this can be mathematically expressed as

\[
k_{\text{eff}} = \frac{k_m k_f}{k_m V_f + (1 - V_f) k_f}
\]

(2.3)

The Rule-of-Mixtures has also been used to calculate the effective thermal diffusivity (Taylor and Kelsic, 1986).

\[
\alpha_{\text{eff}} = \frac{V_f k_f + V_m k_m}{V_f (\rho c)_f + V_m (\rho c)_m}
\]

(2.4)

Here, \( V_m \) is the matrix volume fraction and \( (\rho c)_f \) and \( (\rho c)_m \) are the volumetric heat capacities of the fiber and matrix, respectively.

As indicated by Progelhof, et al. (1976), none of the correlations developed accurately predict the thermal properties of all types of composites. A review of additional models used to predict the thermal conductivity of composite systems is given.
by Progelhof, et al. (1976). Beran and Silnutzer (1971) presented upper and lower bounds for the effective thermal conductivity of a fiber-reinforced composite in terms of volume fractions and a geometric factor. They found that the effective thermal conductivity could be significantly increased by changing the packing geometry.

In addition to the analytical models used to estimate thermal properties, numerical methods have also been incorporated. Havis, et al. (1989) developed a numerical model using the finite difference method that calculated the effective thermal conductivity of aligned fiber composites when the fiber to matrix conductivity ratio was greater than one. James and Harrison (1992) extended this finite difference method to enable the calculation of the temperature distribution and effective thermal conductivity in composite materials made from anisotropic materials. The standard finite difference equations were modified on a node-by-node basis to take into account anisotropy by local re-orientation of the grid. A finite difference method has also been used by James and Keen (1985) to calculate the thermal conductivity of uniaxial fiber composites. The effective thermal conductivity was then found from the fiber-matrix ratio for a range of fiber volume fractions. This finite difference approach was modified by James, et al. (1987) to calculate the transverse thermal conductivity of continuous fiber composites in which the fibers can be at any angle to the faces of the sample.

In addition to the finite difference approach, finite elements has also been used to predict thermal properties. A finite element analysis of a unit-cell approach was used by Han and Cosner (1981) to measure the effective thermal conductivity of fibrous composites for two different geometrical arrangements of the fibers, rectangular and
staggered. Their analysis assumed prior knowledge of the geometry and thermal conductivities of the composite constituents. Veyret, et al. (1993) also used a finite element formulation to determine the effective thermal conductivity of a composite material using the Laplace equation.

Other methods have also been used to determine thermal properties. One such method is based on the analogy between the response of a unidirectional composite to longitudinal shear loading and to transverse heat transfer (Springer and Tsai, 1967). In this approach, the thermal conductivities of unidirectional composites were predicted by replacing the composite stiffness with the thermal conductivity and the shear modulus ratio with the thermal conductivity ratio of the components in the numerical solutions obtained for the shear loading problem. Ishikawa (1980) used a method that was equivalent to that used by Springer and Tsai. His method was again based on the longitudinal shear problem and measured the thermal conductivities of unidirectional, carbon-epoxy composite systems using an apparatus based on the infra-red radiation method. These analytical results were obtained using a Fourier series analysis and required knowledge of the thermal conductivity of the matrix and the fiber volume fraction.

Another technique presented by Behrens (1968) used the method of long waves to obtain the average thermal conductivity. By calculating the thermal waves damping coefficients in the principal directions of the medium, Behrens was able to develop explicit expressions for the average thermal conductivity. In addition, Mottram (1992) developed design charts to estimate the effective longitudinal and transverse thermal conductivity.
conductivities of continuous composites using only the fiber and matrix properties.

2.2 Minimization Methods Used for the Estimation of Thermal Properties

An alternate procedure for estimating the thermal properties of composite materials is to use a minimization technique. One minimization technique frequently used is the Gauss linearization method. This is an iterative procedure that involves the minimization of the least squares function. Beck (1963) was the first to use this minimization procedure to estimate thermal properties, namely thermal diffusivity.

2.2.1 Gauss Linearization Method

The Gauss Linearization method, which is based on the least squares function, is one of the more popular estimation methods used. This method not only allows for the simultaneous estimation of the thermal properties, but also enables validation of the transient heat conduction equation. A least squares function, as given by Beck and Arnold (1977), is

\[ S = [Y - T(\beta)]^T[Y - T(\beta)] \]  \hspace{1cm} (2.5)

where \( Y \) is a vector containing measured temperatures, \( T(\beta) \) is a vector containing calculated temperatures, and \( \beta \) is the true parameter vector. Here, the thermal properties are found by minimizing the square of the difference between the measured temperatures and the calculated temperatures. For continuous, transient temperature measurements, the
The sum of squares function is minimized with respect to the parameters using the Taylor series approach. This is done by differentiating $S$ with respect to $\mathbf{b}$, setting the resulting equation equal to zero, and then solving for $\mathbf{b}$, the estimated parameter vector for $\mathbf{b}$. This method, as described by Beck and Arnold (1977), is one of the simplest and most effective methods for seeking minima which are reasonably well-defined provided that the initial estimates are in the general region of the minimum. However, as explained by Box and Kanemasu (1972), if poor initial estimates for the parameters are used or severe non-linearity in the model exists, this method may cause large oscillations to occur from one iteration to another which leads to non-convergence of the estimates. In an attempt to improve the Gauss method, Box and Kanemasu (1972) modified it by changing the step size used in seeking the minimum. However, this method still did not include a check that the sum of squares function, $S$, decreased from iteration to iteration. Bard (1970) modified the Box-Kanemasu method to include this check; if the function was not decreasing, the step size is reduced by one-half.

The Gauss estimation procedure was used by Beck when he determined the thermal conductivity and specific heat of nickel simultaneously from transient temperature measurements (1966a) and the thermal contact conductance for both steady-state and transient conditions with a periodic contact (1988). Scott and Beck (1992a) also used this method to simultaneously estimate the thermal conductivity and volumetric heat capacity of carbon composites as functions of temperature and fiber orientation. They found that the thermal properties increased with temperature over the range studied and different stacking orientations resulted in significantly different thermal conductivity values. This
method was also used by Scott and Beck (1992b) to develop an estimation methodology for thermoset composite materials during curing, and by Xu and Bao (1990) to simultaneously estimate thermal conductivity and diffusivity.

Loh and Beck (1991) performed a two-dimensional analysis using this estimation procedure to simultaneously determine the effective thermal conductivities of anisotropic thermoset carbon composites parallel and perpendicular to the fiber axis. They found that the conductivity parallel to the fibers is about seven times higher than transverse to the fibers. In addition, Jurkowski, et al. (1992) used this method to simultaneously estimate the thermal conductivity and thermal contact resistance, as did Garnier, et al. (1992) to simultaneously estimate thermal conductivity and volumetric heat capacity without internal temperature measurements. Instead, temperature measurements were made with thin resistance thermometers and thermocouples. Using finite differences to describe the heat transfer model, Pfahl and Mitchel (1970) used this minimization technique to estimate six thermal properties of a charring carbon-phenolic material. The calculated property values were shown to be in good agreement with values from conventional tests.

2.3 Optimal Experimental Designs

Reliable estimation of thermal properties is extremely important in the utilization of composite materials. The accuracy of these estimates can be increased if the experiments are designed carefully. A carefully designed experiment is one in which there is minimum correlation between the estimated properties, as well as maximum
sensitivity of the measured experimental variables to changes in the properties being estimated (Beck and Arnold, 1977). To create such optimal experimental designs, optimal experimental parameters should first be determined. Many criteria have been proposed for the design of optimal experiments. Beck and Arnold (1977) have listed some of these criteria that are all in terms of the product of the sensitivity coefficients and their transpose ($X^T X$). These coefficients are the derivative of temperature with respect to the parameters being estimated. The proposed criteria are (1) maximization of the determinant of $X^T X$, (2) maximization of the minimum eigenvalue of $X^T X$, and (3) maximization of the trace of $X^T X$. The first method was chosen in this study because it has the effect of minimizing the confidence intervals of the resulting estimates.

This optimization method was used by Beck to determine the optimal experiments for the simultaneous estimation of thermal conductivity and specific heat (1969) and to determine the optimal transient experimental design for estimating the thermal contact conductance (1966b). Taktak, et al. (1991) also used this technique to determine the optimal heating time of an applied heat flux, optimal number of temperature sensors, and the optimal temperature sensor location for the estimation of thermal conductivity and volumetric heat capacity of a semi-infinite and a finite thickness composite material.

As explained, several methods for estimating the thermal properties of composite materials have been proposed. These include both experimental methods and the use of mathematical models. The procedure used in this study to estimate the thermal properties is a modification of the Gauss Linearization method discussed in Section 2.2.1. This method was chosen because it allows for the effective thermal conductivity and effective
volumetric heat capacity to be estimated simultaneously. Also, when using this technique, optimal experiments can be designed resulting in more accurate parameter estimates.
Chapter 3

Theoretical Analysis

In this chapter, the theoretical development used to determine the optimal experimental designs for both isotropic and anisotropic composite materials is presented. The minimization procedure used to estimate the effective thermal conductivity perpendicular to the fiber axis and the effective volumetric heat capacity of a carbon fiber-epoxy matrix composite is also discussed. Recall that this estimation procedure requires both experimental and calculated temperatures. In this study, both exact analytical temperature solutions and numerical temperature solutions were obtained, with the two results being compared to determine the accuracy of the numerical results. The numerical solutions were calculated using a finite element program called Engineering Analysis Language (EAL, Whetstone, 1983). This finite element software was utilized because of the need for future analyses of complex structures, typical in aerospace components, for which exact solutions are either complicated or unavailable.

The first section of this chapter focuses on the mathematical models used to describe one-dimensional (isotropic) and two-dimensional (anisotropic) heat conduction.
processes. The second section describes the mathematical details of the parameter estimation technique used in both the exact and numerical analyses to estimate the thermal properties. Note that in both cases, the thermal properties estimated were the effective properties of the composite, not of the individual fiber and matrix components. In the final section, the mathematical criterion used to design optimal experiments, resulting in greater accuracy of the thermal properties, is discussed.

3.1 Mathematical Models Used in Estimating the Thermal Properties of Composite Materials

The formulation of a mathematical model is based on the experimental system being analyzed. In this investigation, formulating mathematical models, either exact or numerical, to describe the conductive heat transfer occurring within the composite sample will allow for the temperature distribution to be calculated. This distribution is required for the estimation of the thermal properties. As mentioned, both one-dimensional and two-dimensional heat conduction analyses have been conducted. The mathematical formulation behind both are defined in the following two subsections.

3.1.1 One-Dimensional Analysis - Isotropic Composite Material

For the isotropic situation, one-dimensional heat conduction through a carbon-epoxy composite was investigated. Note that this isotropic situation is equivalent to analyzing the properties in one direction of an anisotropic composite, as was the case in
this study. The samples used consisted of a thin, flat disk with an aspect ratio such that the two-dimensional effects at the edges can be ignored. One plane boundary had an imposed heat flux perpendicular to the fiber axis, and a known, constant temperature existed at the second boundary, as shown in Fig. 3.1. Since composite materials tend to have low thermal conductivities in directions perpendicular to the fibers, this isothermal boundary condition is readily available. The heat flux boundary condition is required for the independent estimation of the thermal properties. This requirement occurs because this type of boundary condition introduces a new equation into the model which contains only the thermal conductivity and not the volumetric heat capacity. This equation is known as Fourier's Law and is given by

\[ q_x = -k_e \cdot \frac{\partial T}{\partial x} \]  

(3.1)

where \( q_x \) is the applied heat flux. If this boundary condition was not used, and instead, a constant temperature or insulated condition was used, then only the thermal diffusivity \( (k/pc_p) \) could be estimated.

The formulation to describe this problem can be found from an energy balance and is expressed as

\[ \frac{\partial}{\partial x} \left( k_{x,ef} \cdot \frac{\partial T}{\partial x} \right) = C_{ef} \cdot \frac{\partial T}{\partial t}, \quad 0 < x < L_x, \quad t > 0 \]  

(3.2)

where \( T \) is temperature, \( k_{x,ef} \) and \( x \) are the effective thermal conductivity and position, respectively, in the direction of heat transfer, \( C_{ef} \) is the effective volumetric heat capacity.
Figure 3.1. Experimental Set-Up for the Estimation of the Effective Thermal Conductivity and Volumetric Heat Capacity of an Isotropic Material.
(or product of density and specific heat), and \( t \) is time. The heat flux and constant temperature boundary and initial conditions can be described as

\[
-k_x \frac{\partial T}{\partial x} = q_x \quad x = 0 \quad 0 < t < t_h
\]

\[
= 0 \quad x = 0 \quad t > t_h \tag{3.3a,b}
\]

\[
T(x,t) = T_{o,x} \quad x = L_x \quad t > 0 \tag{3.4}
\]

\[
T(x,t) = T_i \quad 0 \leq x \leq L_x \quad t = 0 \tag{3.5}
\]

where \( t_h \) is the time that the heat flux is applied to the sample. After this time, the boundary condition becomes insulated, as seen by Eqs. (3.3a,b). The heat flux, \( q_x \), the temperature at \( x = L_x (T_{o,x}) \), and the initial temperature, \( T_i \), are assumed to be known without errors. Note that two solutions were required for this analytical problem; one while the heat flux was applied and one after the duration of the heat flux. Also, since the experiments were conducted at room temperature, it was assumed that the temperature at \( x = L_x \) was equal to the initial temperature; i.e. \( T_{o,x} = T_i \). Using these assumptions, the exact solutions to describe the temperature distributions were obtained using Green’s function (Beck, et al., 1992). The Green’s function required for this solution is given by

\[
G(x,t|x',\tau) = \frac{2}{L_x} \sum_{n=1}^{\infty} \cos \left( \frac{\beta_n x}{L_x} \right) \cos \left( \frac{\beta_n x'}{L_x} \right) \exp \left( -\frac{\beta_n^2 k_{x-eff}(t-\tau)}{L_x^2 C_{eff}} \right) \tag{3.6}
\]

where \( \beta_n \) is an eigenvalue represented by

\[
\beta_n = \pi \left( n - \frac{1}{2} \right) \tag{3.7}
\]
solved for, resulting in the following:

\[
T(x,t) = T_{ox} + \frac{q_x L_x}{k_{x-eff}} \left[ 1 - \frac{x}{L_x} - 2 \sum_{n=1}^{\infty} \frac{1}{\beta_n^2} \cos \left( \frac{\beta_n x}{L_x} \right) \exp \left( -\frac{\beta_n^2 k_{x-eff} t}{C_{eff} L_x^2} \right) \right]
\]  

(3.8)

for \( 0 < t < t_h \), and

\[
T(x,t) = T_{ox} - \frac{q_x L_x}{k_{x-eff}} \sum_{n=1}^{\infty} \frac{1}{\beta_n^2} \cos \left( \frac{\beta_n x}{L_x} \right) \left[ \exp \left( -\frac{\beta_n^2 k_{x-eff} t}{C_{eff} L_x^2} \right) - \exp \left( -\frac{\beta_n^2 k_{x-eff} (t-t_h)}{C_{eff} L_x^2} \right) \right]
\]  

(3.9)

for \( t > t_h \).

The temperature solution was also obtained numerically from the finite element software, EAL, using an implicit transient analysis. In EAL, the weighted residual method is used to derive the implicit time integration equations. During each time step, the temperature vector is approximated by

\[
(C + \Delta t K)T_{i+1} = (C - \Delta t K)T_i + F \Delta t + \ddot{F} \Delta t^2
\]  

(3.10)

where \( T_i \) is the temperature vector at time \( t_i \), \( T_{i+1} \) is the temperature vector at time \( t_{i+1} \), \( \Delta t \) is the time step size, \( C \) is the capacitance matrix, \( K \) is the stiffness matrix, and \( F \) is the matrix containing the boundary conditions. (Whetstone, 1983). Again, a numerical approach was utilized for the future need to analyze complex structures which do not have exact solutions available.

### 3.1.2 Two-Dimensional Analysis - Anisotropic Composite Material

The two-dimensional analysis is similar to the one-dimensional analysis, only now,
two-dimensional heat conduction through an anisotropic composite sample is considered. Two different experimental configurations were used in this analysis. The first consists of an imposed heat flux perpendicular to the fiber axis over a portion of one boundary (with the remainder of the boundary insulated) and known constant temperatures at the remaining three boundaries, as shown in Fig. 3.2. The second configuration also has a heat flux imposed over a portion of one boundary, only now, the boundary opposite to the heat flux is maintained at a constant temperature, while the remaining two boundaries are insulated, as shown in Fig. 3.3. For both experimental assemblies, the heat flux boundary condition will allow for the determination of thermal conductivity in two directions. However, the actual estimation of these thermal conductivities will not be performed in this study; only the experimental designs required for this estimation process will be analyzed (Section 3.3).

The temperature distribution within the material for both configurations can be determined from conservation of energy

$$\frac{\partial}{\partial x} \left( k_x \frac{\partial T}{\partial x} \right) + \frac{\partial}{\partial y} \left( k_y \frac{\partial T}{\partial y} \right) = C_v \frac{\partial T}{\partial t} \quad 0 < x < L_x \quad 0 < y < L_y \quad t > 0 \quad (3.11)$$

where, in this case, $k_y$ and $y$ are the effective thermal conductivity and position, respectively, perpendicular to the direction of heat transfer. The temperature solutions obtained for both configurations are discussed in the following two subsections.
Figure 3.2. Experimental Set-up Used for Configuration 1 in the Estimation of the Effective Thermal Conductivities in Two Orthogonal Planes.

Figure 3.3. Experimental Set-up Used for Configuration 2 in the Estimation of the Effective Thermal Conductivities in Two Orthogonal Planes.
3.1.2.1 Configuration 1 - Isothermal Boundary Conditions

The heat flux and isothermal boundary conditions and the initial temperature condition for Configuration 1 (Fig. 3.2) can be described as

\[-k_x \frac{\partial T}{\partial x} = q_x \quad x = 0 \quad 0 < y < L_{p,1} \quad 0 < t < t_h\]

\[= 0 \quad x = 0 \quad 0 < y < L_{p,1} \quad t > t_h \quad (3.12a,b)\]

\[\frac{\partial T}{\partial x} = 0 \quad x = 0 \quad L_{p,1} < y < L_y \quad t > 0 \quad (3.13)\]

\[T(x,y,t) = T_{o,x} \quad x = L_x \quad 0 < y < L_y \quad t > 0 \quad (3.14)\]

\[T(x,y,t) = T_{o,y1} \quad 0 < x < L_x \quad y = 0 \quad t > 0 \quad (3.15)\]

\[T(x,y,t) = T_{o,y2} \quad 0 < x < L_x \quad y = L_y \quad t > 0 \quad (3.16)\]

\[T(x,y,t) = T_i \quad 0 < x < L_x \quad 0 < y < L_y \quad t = 0 \quad (3.17)\]

where \(q_x\) is the applied heat flux, \(T_{o,x}\), \(T_{o,y1}\), and \(T_{o,y2}\) are the known temperature boundary conditions, \(L_x\) is the thickness of the plate in the \(x\) direction, \(L_y\) is the thickness of the plate in the \(y\) direction, \(L_{p,1}\) is the portion of the plate where the heat flux is imposed, and \(T_i\) is the initial temperature. The specific value for \(L_{p,1}\) will be found using the optimization procedure discussed in Section 3 of this chapter. Note that once again, two solutions are required for this analytical case; one while the heat flux is applied and one after the duration of the heat flux. Also, since the experiments were again conducted at room temperature, it is assumed that \(T_{o,x} = T_{o,y1} = T_{o,y2} = T_i\). Using these assumptions, the solutions to describe the temperature distribution within the composite sample were
obtained using Green’s functions. For the two-dimensional case, two Green’s functions are required for the temperature solution; one for both the \(x\) and \(y\) direction boundary conditions. The Green’s function for the heat transfer along the \(x\) axis is provided in Eq. (3.6), and the Green’s function along the \(y\) axis is given by (Beck, et al., 1992).

\[
G_y(y, t | y', \tau) = \frac{2\kappa_{xy}^2}{L_y} \sum_{m=1}^{\infty} \sin\left(\frac{m\pi y}{L_y}\right) \sin\left(\frac{m\pi y'}{L_y}\right) \exp\left(-\frac{m^2\pi^2 k_{y, eff}(t-\tau)}{L_y^2 C_{eff}}\right) \tag{3.18}
\]

where \(\kappa_{xy}\) is the effective thermal conductivity ratio, \((k_{y, eff}/k_{x, eff})\). Using these Green’s functions, the temperature solutions for Configuration 1 are represented by

\[
T(x, y, t) = T_{ox} + \frac{4q_x L_x}{k_{x, eff}} \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} \sin\left(\frac{m\pi y}{L_y}\right) \cos\left(\frac{\beta_n x}{L_x}\right) \left[1 - \cos\left(\frac{m\pi L_{p,1}}{L_y}\right)\right] \cdot \left(\frac{1}{mB}\right) \left[1 - \exp(-At)\right] \tag{3.19}
\]

for \(0 < t < t_h\), and

\[
T(x, y, t) = T_{ox} + \frac{4q_x L_x}{k_{x, eff}} \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} \sin\left(\frac{m\pi y}{L_y}\right) \cos\left(\frac{\beta_n x}{L_x}\right) \left[1 - \cos\left(\frac{m\pi L_{p,1}}{L_y}\right)\right] \cdot \left(\frac{1}{mB}\right) \left[\exp[-A(t-t_h)] - \exp(-At)\right] \tag{3.20}
\]

for \(t > t_h\), where

\[
A = \frac{m^2\pi^2 k_{y, eff}}{L_y^2 C_{eff}} + \frac{\beta_n^2 k_{x, eff}}{L_x^2 C_{eff}} \tag{3.21}
\]

\[
B = m^2\pi^2 L_y^2 \kappa_{xy} + \beta_n^2 \tag{3.22}
\]
and $L_{xy}$ is the ratio of the composite dimensions ($L_x/L_y$).

### 3.1.2.2 Configuration 2 - Isothermal and Insulated Boundary Conditions

The heat flux and isothermal boundary conditions and the initial temperature condition for Configuration 2 (Fig. 3.3) can be described as

\[
-k_x \frac{\partial T}{\partial x} = q_x, \quad x = 0, \quad 0 < y < L_{p,2}, \quad 0 < t < t_h
\]

\[
\frac{\partial T}{\partial x} = 0, \quad x = 0, \quad 0 < y < L_{p,2}, \quad t > t_h \tag{3.23a,b}
\]

\[
\frac{\partial T}{\partial x} = 0, \quad x = 0, \quad L_{p,2} < y < L_y, \quad t > 0 \tag{3.24}
\]

\[
T(x,y,t) = T_{o,x}, \quad x = L_x, \quad 0 < y < L_y, \quad t > 0 \tag{3.25}
\]

\[
\frac{\partial T}{\partial y} = 0, \quad 0 < x < L_x, \quad y = 0, \quad t > 0 \tag{3.26}
\]

\[
\frac{\partial T}{\partial y} = 0, \quad 0 < x < L_x, \quad y = L_y, \quad t > 0 \tag{3.27}
\]

\[
T(x,y,t) = T_i, \quad 0 < x < L_x, \quad 0 < y < L_y, \quad t = 0 \tag{3.28}
\]

where $L_{p,2}$ is the portion of the plate where the heat flux is imposed. Again, the specific value for $L_{p,2}$ will be found using the optimization procedure discussed in Section 3 of this chapter. Due to the different boundary conditions used in the two configurations, $L_{p,2}$ will be different than $L_{p,1}$ (the heat flux position calculated for Configuration 1). Since the experiments were again conducted at room temperature, the same assumption was used as for Configuration 1; i.e., $T_{o,x} = T_i$. The solutions to describe the temperature distribution within the composite sample were then obtained using Green's functions. Two Green's functions are again required for this configuration, one for both the $x$ and $y$ direction boundary conditions. The Green's function along the $x$ axis is provided in Eq.
(3.6), and the Green’s function along the y axis is given by (Beck, et al., 1992)

\[ G_y(y,t|y',\tau) = \frac{L_y^{1/2}}{L_y^{1/2}} \left[ 1 + 2 \sum_{n=1}^{\infty} \cos \left( \frac{m \pi y}{L_y} \right) \cos \left( \frac{m \pi y'}{L_y} \right) \exp \left( -m^2 \pi^2 k_{y-eff} (t-\tau) \right) \right] \]  

(3.29)

Using these Green’s functions, the temperature solutions for Configuration 2 are represented by

\[ T(x,y,t) = T_{ox} + \frac{2q_x L_x L_{p,2}}{k_{x-eff} L_y} \sum_{n=1}^{\infty} \frac{1}{\beta_n^2} \cos \left( \frac{\beta_n x}{L_x} \right) \left[ 1 - \exp(-Ct) \right] \]

\[ + \frac{4q_x(t)L_x}{\pi k_{x-eff}} \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} \cos \left( \frac{\beta_n x}{L_x} \right) \cos \left( \frac{m \pi y}{L_y} \right) \sin \left( \frac{m \pi L_{p,2}}{L_y} \right) \left( \frac{1}{m B} \right) [1 - \exp(-At)] \]  

(3.30)

for \( 0 < t < t_h \), and

\[ T(x,y,t) = T_{ox} + \frac{2q_x L_x L_{p,2}}{k_{x-eff} L_y} \sum_{n=1}^{\infty} \frac{1}{\beta_n^2} \cos \left( \frac{\beta_n x}{L_x} \right) \left[ e^{(-C(t-t_h))} - e^{-Ct} \right] \]

\[ + \frac{4q_x(t)L_x}{\pi k_{x-eff}} \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} \cos \left( \frac{\beta_n x}{L_x} \right) \cos \left( \frac{m \pi y}{L_y} \right) \sin \left( \frac{m \pi L_{p,2}}{L_y} \right) \left( \frac{1}{m B} \right) [e^{(-A(t-t_h))} - e^{(-At)}] \]  

(3.31)

for \( t > t_h \), where \( A \) and \( B \) are given by Eqs. (3.21) and (3.22), respectively, and \( C \) is represented by

\[ C = \frac{\beta_n^2 k_{x-eff}}{L_x^2 C_{eff}} \]  

(3.32)

In determining these temperature distributions as functions of time, one should note that there are steady state terms which need to be calculated only once since they are time
invariant. This is important since these series are slow to converge and require hundreds of terms, whereas the time varying terms of the summation converge rather quickly. An alternate solution method involves the use of time partitioning (Beck, et al., 1992). In this method, the solution is partitioned into two regions and both large-time and small-time Green's functions are used to find the temperature. For example, at early times, the solution is the same as that for a semi-infinite body, and therefore, the overall solution can be divided up into early and steady state solutions.

3.2 Minimization Procedure Used in Estimating the Thermal Properties

The method used to estimate the thermal properties is based on the minimization of an objective function with respect to the unknown parameters, effective thermal conductivity and effective volumetric heat capacity. This procedure is called the Gauss method and allows for the simultaneous estimation of the thermal properties. A modification of the Gauss method that allows for nonlinearities in the model to exist is the Box-Kanemasu method, which is utilized in this investigation. In this method, the objective function used is the least-squares function, \( S \), and is given by

\[
S = [Y - T(\hat{B})]^T [Y - T(\hat{B})]
\]  

\( (3.33) \)

(Beck and Arnold, 1977). Here, \( Y \) is the measured temperature vector, \( T(\hat{B}) \) is the calculated temperature vector found using a transient mathematical model (as given in Eqs. (3.8-9), (3.19-20), and (3.30-31)) and the parameter estimates, and \( \hat{B} \) is the exact
parameter vector that contains the unknown thermal properties. The objective function, $S$, is minimized with respect to the unknown parameters, $\beta$. This is done by differentiating $S$ with respect to $\beta$ and setting the resulting equation equal to zero, giving

$$\nabla_\beta S = 2[-X^T(\beta)] [Y - T(\beta)] = 0$$

(3.34) (Beck and Arnold, 1977). Here, the sensitivity coefficient matrix, $X(\beta)$ is defined as

$$X(\beta) = [\nabla_\beta T^T(\beta)]^T$$

(3.35)

These coefficients are the derivatives of temperature with respect to the parameters being estimated and represent the sensitivity of the temperature response with respect to changes in the unknown parameters. In order for the parameters to be estimated simultaneously, the determinant of the sensitivity coefficients and their transpose, $|X^TX|$, cannot equal zero. That is, any one column of $X$ cannot be expressed as a linear combination of any other column.

Because the heat conduction process in this study is a non-linear problem, the estimator, $\beta$, cannot easily be solved for. Therefore, two approximations are used in Eq. (3.34) to prevent this difficulty; (1) Replace $X(\beta)$ by $X(b)$, where $b$ is an estimate of $\beta$, and (2) Use the first two terms of a Taylor series for $T(\beta)$ about $b$ to approximate $T(\beta)$ (Beck and Arnold, 1977). Using these approximations and implementing an iterative scheme, Eq. (3.34) can be solved for $b$, the estimated parameter vector, resulting in the following expression for $b^{(k+1)}$:

$$b^{(k+1)} = b^{(k)} + P^{(k)}[X^{T(k)} (Y - T^{(k)})]$$

(3.36)

where
\[ P^{(k)} = [X^{(k)}T X^{(k)}]^{-1} \] (3.37)

This is known as the Gauss linearization equation. Here, \( k \) is the iteration number, \( b^{(k+1)} \) is the new parameter estimate, \( b^{(k)} \) is the estimate at the previous iteration, and \( T(b)^{(k)} \) contains temperatures calculated using \( b^{(k)} \).

For a nonlinear problem, Eq. (3.36) is altered and becomes

\[ b^{(k+1)} = b^{(k)} + h^{(k+1)} \Delta g^{(k)} \] (3.38)

where

\[ \Delta g^{(k)} = P^{(k)}[X^{(k)} (Y - T^{(k)})] \] (3.39)

and \( h^{(k+1)} \) is a scalar interpolation function. To use this nonlinear estimation procedure, an initial estimate, \( b^{(0)} \), is required. This estimate is then used to calculate \( T^{(0)} \) and \( X^{(0)} \) which are used to obtain the improved parameter vector, \( b^{(i)} \). This procedure continues until all parameters in \( b \) do not change significantly (Beck and Arnold, 1977).

Equation (3.38) represents the Box-Kanemasu method which is a modification of the Gauss method. In the Box-Kanemasu method, the sum of squares, \( S \), is approximated at each iteration by a quadratic function in \( h \). The minimum \( S \) is located where the derivative of \( S \) with respect to \( h \) is equal to zero, or at an \( h \) value of (Beck and Arnold, 1977)

\[ h^{(k+1)} = G^{(k)} \alpha^2 [S^{(k)}_e - S^{(k)}_o + 2G^{(k)} \alpha]^{-1} \] (3.40)

where

\[ G^{(k)} = [\Delta g^{(k)}]^{T} (X^{(k)} [\Delta g^{(k)}]) \] (3.41)
The parameter for $\alpha$ is initially set equal to one and $S_a^{(k)}$ and $S_o^{(k)}$ are the values of $S$ at $\alpha$ and zero, respectively. If $S_a^{(k)}$ is not less than $S_o^{(k)}$, $\alpha$ is reduced by one-half and the inequality is checked again. This is a modification over the original Box-Kanemasu method. A flow chart illustrating the modified Box-Kanemasu estimation procedure, as presented by Beck and Arnold (1977), is shown in Fig. 3.4. Note that if the investigation requires $\alpha$ to become less than 0.01, the calculations are terminated. One reason why this may occur is that correlation (or linear dependence) between the sensitivity coefficients exists, causing the sum of squares function not to have a unique minimum. It is therefore very important to calculate and analyze the sensitivity coefficients for possible correlation to ensure reliable parameter estimates.

A parameter estimation program was written using the modified Box-Kanemasu method and is called MODBOX; this program is based on the original program NLINA, by Beck (1993). This program uses sequential in-time estimation to calculate the parameters at each time step. The exact mathematical models given in Eqs. (3.8) and (3.9) were used in this program as well as the derived sensitivity coefficients, allowing for the estimation of the effective thermal conductivity perpendicular to the fibers and the effective volumetric heat capacity of a composite consisting of IM7 graphite fibers and a Bismaleimide epoxy matrix. The modified Box-Kanemasu method was also implemented into EAL where the temperature solution was obtained numerically. Again, the same effective thermal properties were estimated. The advantage of this sequential estimation technique is that it allows the user to observe the effects of additional data on the sequential estimates and study the validity of the proposed mathematical model and
Figure 3.4 Flow Chart for the Modified Box-Kanemasu Estimation Procedure
experimental design. Ideally, at the conclusion of an experiment, any additional data should not affect the parameter estimates.

### 3.3 Optimal Experimental Designs Used in Estimating Thermal Properties of Composite Materials

Since the Gauss method requires experimental temperatures of the composite system to be measured, the accuracy of the thermal properties estimated can be greatly increased if these experiments are designed carefully. To create such optimal experimental designs, optimal experimental parameters must first be determined. The focus of this section is on the criterion used in obtaining these optimal parameters. For the one-dimensional analysis, the experimental design consisted of a thin plate with an imposed heat flux applied for a finite duration at one boundary and a known, constant temperature at the second boundary. For this design, the optimal experimental parameters that were determined are the heating time, temperature sensor location, and total experimental time.

For the two-dimensional heat conduction analysis, two different configurations were used, allowing for the effective thermal conductivity in two directions and the effective volumetric heat capacity to be determined simultaneously. Both designs had a heat flux imposed over a portion of one boundary, with the remainder of the boundary insulated. In addition, Configuration 1 had known, constant temperatures at the remaining three boundaries, while Configuration 2 had a constant temperature at the boundary.
opposite to the heat flux, and insulated conditions at the remaining two boundaries. Therefore, in addition to the optimal experimental parameters found for the one-dimensional case, the optimal position of the heat flux was also determined for both configurations used in the two-dimensional case. Note, however, that this optimal heat flux location will not be the same for both configurations due to the different boundary conditions used.

3.3.1 Design Criterion Used for Optimal Experimental Designs

Many criterion have been proposed for the design of optimum experiments. As mentioned previously, the sensitivity coefficients indicate the sensitivity of temperature to changes in the thermal properties and optimal experiments are those which maximize these coefficients for each property. Therefore, the criterion chosen for this analysis is the maximization of the determinant \((D^+)\) of \(X^T X^+\), which contains the product of the dimensionless sensitivity coefficients and their transpose (Beck and Arnold, 1977). This criterion is subject to a maximum temperature rise, a fixed number of measurements, and the following seven standard statistical assumptions: additive, zero mean, constant variance, uncorrelated normal errors with errorless independent variables, and no prior information. It is recommended by Beck and Arnold because it has the effect of minimizing the confidence intervals of the resulting parameter estimates. Note, it was desired to perform the optimization procedure in non-dimensional terms so the results could be applicable for any material, not just composite materials.

For the one-dimensional analysis where two properties are estimated \((k_{\text{eff}}\) and \(C_{\text{ef}}\),
\[ |X^+X^+| \] is a 2 x 2 matrix. Therefore, the dimensionless determinant is given as

\[ D_{i-D} = \begin{vmatrix} d_{11}^+ & d_{12}^+ \\ d_{12}^+ & d_{22}^+ \end{vmatrix} = d_{11}^+d_{22}^+ - (d_{12}^+)^2 \] (3.42a,b)

where \( d_{ij}^+, d_{12}^+, \) and \( d_{22}^+ \) are found from (Beck and Arnold, 1977)

\[ d_j^+ = \left[ \frac{1}{T_{\text{max}}^2} \right] \left[ \frac{1}{M_t_N} \right] \sum_{p=1}^{M} \int_0^{t_i^*} X_i^+(t^*)X_j^+(t^*) \, dt \] (3.43)

In this equation, \( M \) is the number of temperature sensors used and \( t^*, t_N^+, \) and \( T_{\text{max}}^+ \) are defined as

\[ T_{\text{max}}^+ = \frac{(T_{\text{max}} - T_{o,x})}{q_x L_j/k_{x-eff}} \]

\[ t^* = \frac{k_{x-eff} f}{C_{eff} I_x^2} \]

\[ t_N^+ = \frac{k_{x-eff} I_N}{C_{eff} I_x^2} \] (3.44a-c)

where \( t_N^+ \) is the total experimental time, \( T_{\text{max}}^+ \) is the maximum temperature reached between the start and end of the experiment, and \( T_{o,x}^+ \) is the surface (and in this case, initial) temperature. It should be noted that this definition of \( T_{\text{max}}^+ \) was used to verify previous optimal experimental parameter results by Taktak, et al. (1991) and is not the best representative choice.

The integral in Eq. (3.43) was calculated numerically, being approximated by a summation. From Eq. (3.43), it is evident that the matrix in Eq. (3.42a) is symmetric; i.e., \( d_{12}^+ = d_{21}^+ \). This simplifies the problem by decreasing the number of equations that must be numerically integrated.

When extending this analysis to the two-dimensional case, three properties \( (k_{x-eff}, k_{y-eff}, \) and \( C_{eff}) \) can now be estimated simultaneously for both configurations. Therefore,
\[ |X^*T^+| \] is a 3 x 3 symmetric matrix and the dimensionless determinant is given by

\[
D_{2-D}^+ = \begin{vmatrix} d_{11}^* & d_{12}^* & d_{13}^* \\ d_{12}^* & d_{22}^* & d_{23}^* \\ d_{13}^* & d_{23}^* & d_{33}^* \end{vmatrix}
\]

\[
D_{2-D}^+ = d_{11}^*(d_{22}^*d_{33}^* - d_{23}^*^2) - d_{12}^*(d_{12}^*d_{33}^* - d_{13}^*d_{23}^*) + d_{13}^*(d_{12}^*d_{23}^* - d_{13}^*d_{22}^*) \quad (3.45a,b)
\]

Again, the \( d_{ij}^+ \) values were found from Eq. (3.43), where the integral was calculated numerically. To compare both configurations used in the two-dimensional analysis, the value for \( T_{max}^+ \) was redefined as the temperature reached at steady-state conditions. This is a more accurate choice than the \( T_{max}^+ \) selected for the one-dimensional design, used by Taktak, et al. (1991), because it represents the true maximum temperature that can be attained for the defined problem.

From Eqs. (3.42) and (3.43), it is seen that the dimensionless sensitivity coefficients are required for this optimization procedure; these coefficients are given by

\[
X_{k_{x-\sigma}}^+ = \frac{k_{x-eff}}{q_x/L_x/k_{x-eff}} \frac{\partial T}{\partial k_{x-eff}} \quad (3.46)
\]

\[
X_{c_{\sigma}}^+ = \frac{C_{eff}}{q_x/L_x/k_{x-eff}} \frac{\partial T}{\partial C_{eff}} \quad (3.47)
\]

and

\[
X_{k_{y-\sigma}}^+ = \frac{k_{y-eff}}{q_y/L_y/k_{y-eff}} \frac{\partial T}{\partial k_{y-eff}} \quad (3.48)
\]

where \( X_{k_{x-\sigma}}^+ \) and \( X_{c_{\sigma}}^+ \) are used in the one-dimensional analysis and \( X_{k_{x-\sigma}}^+ \), \( X_{k_{y-\sigma}}^+ \), and \( X_{c_{\sigma}}^+ \) are used in the two-dimensional analysis.
3.3.2 One-Dimensional Optimal Experimental Design Formulation

In performing this optimization procedure, a mathematical model, either exact or numerical, is required to represent the experimental process. An exact model for the one-dimensional analysis is given by the temperature solutions in Eqs. (3.8) and (3.9). Using the following dimensionless variables

\[ x^* = \frac{x}{L_x}, \quad t^* = \frac{k_{x-eff} t}{C_{eff} L_x^2}, \quad t_h^* = \frac{k_{x-eff} t_h}{C_{eff} L_x^2}, \quad T^* = \frac{T-T_{ref}}{q_L/L_x/k_{x-eff}} \]  

these temperature distributions can be expressed in dimensionless form as

\[ T^*(x,t) = 1 - x^* - 2 \sum_{n=1}^{\infty} \frac{1}{\beta_n^2} \cos(\beta_n x^*) \exp(-\beta_n^2 t^*) \]  

for \( 0 < t^* < t_h^* \), and

\[ T^*(x,t) = -2 \sum_{n=1}^{\infty} \frac{1}{\beta_n^2} \cos(\beta_n x^*) \left[ \exp(-\beta_n^2 t^*) - \exp[-\beta_n^2 (t^* - t_h^*)] \right] \]  

for \( t^* > t_h^* \), where \( \beta_n \) is given by Eq. (3.7). This temperature distribution, which is calculated using a dimensionless heating time, \( t_h^* \), equal to the total experimental time, is shown in Fig. 3.5 for several \( x^* \) locations.

The dimensionless sensitivity coefficients, \( X_{k_{x-eff}}^* \) and \( X_{C_{eff}}^* \), were then found by differentiating Eqs. (3.50) and (3.51) with respect to \( k_{x-eff} \) and \( C_{eff} \). The effective thermal conductivity sensitivity coefficients are given by

\[ X_{k_{x-eff}}^* = (x^* - 1) + 2 \sum_{n=1}^{\infty} \left( \frac{1}{\beta_n^2} + t^* \right) \cos(\beta_n x^*) \exp(-\beta_n^2 t^*) \]
Figure 3.5. Dimensionless Temperature Distribution ($T^*$) for One-Dimensional Heat Conduction Using a Dimensionless Heating Time, $t_h^*$, Equal to the Total Experimental Time for Several $x^*$ ($x/L_x$) Locations.
for $0 < t^* < t_h^+$, and

$$X_{C_e}^* = 2 \sum_{n=1}^{\infty} \cos(\beta_n x^*) \left[ \frac{1}{\beta_n^2} + t^* \right] e^{-\beta_n^2 t^*} - \left[ \frac{1}{\beta_n^2} + (t^* - t_h^*) \right] e^{-\beta_n^2 (t^* - t_h^*)} \right) \right]$$  \hspace{1cm} (3.53)$$

for $t^* > t_h^+$, while the effective volumetric heat capacity sensitivity coefficients can be expressed as

$$X_{C_e}^* = -2 \sum_{n=1}^{\infty} t^* \exp(-\beta_n^2 t^*) \cos(\beta_n x^*) \hspace{1cm} (3.54)$$

for $0 < t^* < t_h^+$, and

$$X_{C_e}^* = -2 \sum_{n=1}^{\infty} \left[ t^* \exp(-\beta_n^2 t^*) - (t^* - t_h^*) \exp[-\beta_n^2 (t^* - t_h^*)] \right] \cos(\beta_n x^*) \hspace{1cm} (3.55)$$

for $t^* > t_h^+$.

These dimensionless sensitivity coefficients are then used in the optimization procedure to determine the maximum determinant value, as given by Eqs. (3.42) and (3.43), and the corresponding optimal experimental parameters. Viewing these coefficients as functions of experimental time will also give insight into the experimental design, as will be shown in Chapter 5. The sensitivity coefficients in dimensional form are also required in the program, MODBOX, to estimate the effective thermal conductivity and effective volumetric heat capacity simultaneously, as shown in Eqs. (3.36) and (3.37).

### 3.3.3 Two-Dimensional Optimal Experimental Design Formulation

The exact model used to describe the temperature distribution for two-dimensional heat transfer in an anisotropic composite material is given in Eqs. (3.19) and (3.20) for
Configuration 1 and Eqs. (3.30) and (3.31) for Configuration 2. The derived sensitivity coefficients for both configurations required for the optimization procedure are discussed in the following two subsections.

3.3.3.1 Optimal Experimental Design Formulation for Configuration 1

Using the dimensionless variables already given in Eq. (3.49) along with the following non-dimensional variables

\[ y^* = \frac{y}{L_y}, \quad L_{p,i}^* = \frac{L_{p,i}}{L_y}, \quad i=1,2 \]  

(\( i \) corresponds to the configuration number) the temperature distributions for Configuration 1 can be expressed in dimensionless form as

\[ T^*(x^*, y^*, t^*) = \frac{4}{\pi} \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} \sin(m\pi y^*) \cos(\beta_n x^*) \left[ 1 - \cos(m\pi L_{p,i}^*) \right] \left( \frac{1}{mB} \right) \left[ 1 - \exp(-Bt^*) \right] \]  

(3.57)

for \( 0 < t^* < t^+_h \), and

\[ T^*(x^*, y^*, t^*) = \frac{4}{\pi} \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} \sin(m\pi y^*) \cos(\beta_n x^*) \left[ 1 - \cos(m\pi L_{p,i}^*) \right] \left( \frac{1}{mB} \right) \left[ \exp(-B(t^* - t^+_h)) - \exp(-Bt^*) \right] \]  

(3.58)

for \( t^* > t^+_h \), where \( L_{xy} (L_y/L_x) \) and \( \kappa_{xy} (k_{xy,off}/k_{x,eff}) \) are the dimension and effective thermal conductivity ratios, respectively, and \( B \) is given in Eq. (3.22).

The sensitivity coefficients for all three effective parameters, thermal conductivity
perpendicular to the fibers ($k_{x,y}$), thermal conductivity parallel to the fibers ($k_{y,y}$), and volumetric heat capacity ($C_{v}$), were then calculated by differentiating the above temperature distribution with respect to each property. The sensitivity coefficients for the thermal conductivity perpendicular to the fiber axis are given by

$$X_{k_{x,y}}^* = \frac{4}{\pi} \sum_{n=1}^{\infty} \sum_{m=1}^{\infty} \sin(m\pi y^*) \cos(\beta_n x^*) \left[1 - \cos(m\pi L_{y,1}^*)\right] \left(\frac{1}{mB}\right)$$

$$\cdot \left[\beta_n^2 t_0^* \exp(-Bt^*) + (D - 1)(1 - \exp(-Bt^*))\right]$$

(3.59)

for $0 < t^* < t_h^*$, and

$$X_{k_{x,y}}^* = \frac{4}{\pi} \sum_{n=1}^{\infty} \sum_{m=1}^{\infty} \sin(m\pi y^*) \cos(\beta_n x^*) \left[1 - \cos(m\pi L_{y,1}^*)\right] \left(\frac{1}{mB}\right)$$

$$\cdot \left[(D - 1)(e^{1-B(t^*-t_0^*)} - e^{-Bt^*}) + \beta_n^2 \exp(-Bt^* - Bt^*)\right]$$

(3.60)

for $t^* > t_h^*$ where $D$ is equal to

$$D = \left(\frac{m^2 L_{x,y}^2 k_{x,y}}{m^2 L_{x,y}^2 \kappa_{x,y} + \beta_n^2}\right)$$

(3.61)

The dimensionless sensitivity coefficients for $X_{C_{v}}^*$ and $X_{k_{x,y}}^*$ were also calculated; the solutions for $0 < t^* < t_h^*$ are given by

$$X_{C_{v}}^* = \frac{4}{\pi} \sum_{n=1}^{\infty} \sum_{m=1}^{\infty} \sin(m\pi y^*) \cos(\beta_n x^*) \left[1 - \cos(m\pi L_{y,1}^*)\right] \left(-\frac{1}{mB}\right) \left(-Bt^* \exp(-Bt^*)\right)$$

(3.62)

and
and for $t^* > t_h^*$, by

$$X_{c^*} = \frac{4}{\pi} \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} \sin(m\pi y^*) \cos(\beta_n x^*) \left[ 1 - \cos(m\pi L_{p,1}^*) \right] \left[ \frac{1}{mB} \right] \left[ m^2 \pi^2 L_{xy}^2 \kappa_{xy} t^* \exp(-Bt^*) - D(1 - \exp(-Bt^*)) \right]$$

(3.66)

where $B$ and $D$ are given in Eqs. (3.22) and (3.61), respectively.

3.3.3.2 Optimal Experimental Design Formulation for Configuration 2

Using the dimensionless variables given in Eqs. (3.49) and (3.56), the temperature distribution obtained for Configuration 2 (Eqs. (3.30) and (3.31)) can be expressed in dimensionless form as

$$T^*(x^*, y^*, t^*) = 2L_{p,2}^* \sum_{n=1}^{\infty} \frac{1}{\beta_n^2} \cos(\beta_n x^*) \left[ 1 - e^{-\beta_n^2} \right]$$

$$+ \frac{4}{\pi} \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} \cos(\beta_n x^*) \cos(m\pi y^*) \sin(m\pi L_{p,2}^*) \left( \frac{1}{mB} \right) \left[ 1 - e^{-Bt^*} \right]$$

(3.66)
for 0 < \( t^+ < t_h^+ \), and

\[
T^+(x^+, y^+, t^+) = 2L_{p,2}^+ \sum_{n=1}^{\infty} \frac{1}{\beta_n^2} \cos(\beta_n x^+) \left[ e^{\left[-\beta_n(t^+-t_h^+)\right]} - e^{\left[-\beta_n t_h^+\right]} \right]
\]

\[
+ \frac{4}{\pi} \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} \cos(\beta_n x^+) \cos(m\pi y^+) \sin(m\pi L_{p,2}^+) \left( \frac{1}{mB} \right) \left[ e^{\left[-\beta_n(t^+-t_h^+)\right]} - e^{\left[-\beta_n t_h^+\right]} \right]
\]  

(3.67)

for \( t^+ > t_h^+ \).

Again, the sensitivity coefficients for all three effective parameters, thermal conductivity perpendicular to the fibers \( (k_{x,\text{eff}}) \), thermal conductivity parallel to the fibers \( (k_{y,\text{eff}}) \), and volumetric heat capacity \( (C_{e,\text{eff}}) \), were then calculated by differentiating the above temperature distributions with respect to each property. The sensitivity coefficients for the thermal conductivity perpendicular to the fiber axis are given by

\[
X_{k_{x,\text{eff}}} = 2L_{p,2}^+ \sum_{n=1}^{\infty} \cos(\beta_n x^+) \left[ \frac{-1}{\beta_n^2} + \left( t^+ + \frac{1}{\beta_n^2} \right) e^{\left[-\beta_n t_h^+\right]} \right] + \frac{4}{\pi} \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} \cos(\beta_n x^+) \cdot \cos(m\pi y^+) \sin(m\pi L_{p,2}^+) \left( \frac{1}{mB} \right) \left[ (D-1)(1 - e^{\left[-\beta_n t_h^+\right]} + \beta_n^2 t^+ e^{\left[-\beta_n t_h^+\right]} \right]
\]  

(3.68)

for 0 < \( t^+ < t_h^+ \), and

\[
X_{k_{x,\text{eff}}} = 2L_{p,2}^+ \sum_{n=1}^{\infty} \cos(\beta_n x^+) \left[ \left( \frac{1}{\beta_n^2} + t^+ \right) e^{\left[-\beta_n t_h^+\right]} - \left( \frac{1}{\beta_n^2} + (t^+ - t_h^+) \right) e^{\left[-\beta_n(t^+-t_h^+)\right]} \right]
\]

\[
+ \frac{4}{\pi} \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} \cos(\beta_n x^+) \cos(m\pi y^+) \sin(m\pi L_{p,2}^+) \left( \frac{1}{mB} \right) \left[ (D-1)(e^{\left[-\beta_n(t^+-t_h^+)\right]} - e^{\left[-\beta_n t_h^+\right]} + \beta_n^2 t^+ e^{\left[-\beta_n t_h^+\right]} - \beta_n^2 (t^+ - t_h^+) e^{\left[-\beta_n(t^+-t_h^+)\right]} \right]
\]  

(3.69)
for $t^+ > t_h^+$. The dimensionless sensitivity coefficients for $X_{C_{\sigma}}^*$ and $X_{s_{\sigma}}^*$ were also calculated; the solutions for $0 < t^+ < t_h^+$ are given by

\[
X_{C_{\sigma}}^* = -2L_{p,\sigma} \sum_{n=1}^{\infty} t^+ \cos(\beta_n x^+) \cos(m \pi y^+) \sin(m \pi L_{p,\sigma}^+) \left( \frac{1}{mB} \right) (-Bt^* e^{-Br^*}) + \frac{4}{\pi} \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} \cos(\beta_n x^+) \cos(m \pi y^+) \sin(m \pi L_{p,\sigma}^+) \left( \frac{1}{mB} \right) (-Bt^* e^{-Br^*}) \]

\text{(3.70)}

and

\[
X_{s_{\sigma}}^* = \frac{4}{\pi} \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} \cos(\beta_n x^+) \cos(m \pi y^+) \cos(m \pi L_{p,\sigma}^+) \left( \frac{1}{mB} \right) (-D(1 - e^{-Br^*}) + m^2 \pi^2 L_{x,\sigma}^2 k_{\sigma} f^* e^{-Br^*}) \]

\text{(3.71)}

and for $t^+ > t_h^+$, by

\[
X_{C_{\sigma}}^* = 2L_{p,\sigma} \sum_{n=1}^{\infty} \cos(\beta_n x^+) \left[ (t^+ - t_h^+) e^{-B(t^*-t_h^*)} - t^+ e^{-Bt^*} \right] + \frac{4}{\pi} \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} \cos(\beta_n x^+) \cos(m \pi y^+) \sin(m \pi L_{p,\sigma}^+) \left( \frac{1}{mB} \right) \left[ B(t^+ - t_h^*) e^{-B(t^*-t_h^*)} - Bt^* e^{-Br^*} \right] \]

\text{(3.72)}

and

\[
X_{s_{\sigma}}^* = \frac{4}{\pi} \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} \cos(\beta_n x^+) \cos(m \pi y^+) \cos(m \pi L_{p,\sigma}^+) \left( \frac{1}{mB} \right) (-D \left( e^{-Br^*} - e^{-Br^*} \right) + m^2 \pi^2 L_{x,\sigma}^2 k_{\sigma} \left( t^+ e^{-Br^*} - (t^+ - t_h^*) e^{-Br^*} \right) \]

\text{(3.73)}
where $B$ and $D$ are given in Eqs. (3.22) and (3.61), respectively.

Again, as in the one-dimensional analysis, the dimensionless sensitivity coefficients for both configurations will be used in the optimization procedure to determine the maximum determinant and the corresponding optimal experimental parameters.
Chapter 4

Experimental Procedures

This chapter describes the experimental procedure used to estimate the thermal properties of a continuous IM7 graphite fiber - Bismaleimide epoxy matrix composite material. Although optimal experiments were designed for both one-dimensional (isotropic) and two-dimensional (anisotropic) heat conduction, only the one-dimensional experiment was conducted, allowing for the effective thermal conductivity perpendicular to the fibers and the effective volumetric heat capacity to be estimated simultaneously.

As discussed previously in Section 3.2, the estimation procedure used in this study is the modified Box-Kanemasu method. Recall that when using this method, experimental temperatures must be recorded. To estimate the thermal properties independently, the experiments must be transient and one of the boundary conditions must be a heat flux (Beck and Arnold, 1977). With these required conditions, the experimental assemblies were designed accordingly. Discussed next are the experimental set-up and procedure utilized.
4.1 One-Dimensional Experiment for the Estimation of Thermal Properties

The experimental assembly for the one-dimensional analysis used to estimate the thermal properties of the given composite material consists of a thin composite sample subjected to a heat flux perpendicular to the fiber axis at one boundary and a known constant temperature at the other boundary. Temperature measurements were then taken at the flux boundary and were used in the estimation procedure. These experiments are described in detail in the following subsections.

4.1.1 One-Dimensional Experimental Set-Up

The experimental design for one-dimensional heat conduction was composed of two composite disks of approximately equal size, a resistance heater, eight thermocouples, and two copper cylinders. The assembly was symmetrical consisting of, from the center to the top, a thin resistance heater, two thermocouples, the composite sample, two additional thermocouples, and a copper block. The composite sample was 4.77 cm in diameter and 0.678 cm thick. The copper blocks, each with a height of 6.35 cm and a diameter of 5.08 cm, were used as heat sinks to attempt to attain the constant temperature boundary condition while the resistance heater was used to provide the heat flux boundary condition. All of the experiments were conducted at the National Aeronautics and Space Administration - Langley Research Center, Aircraft Structures Branch (NASA-LaRC,ASB) using the equipment available in their testing lab. All supplies required in the experiment, such as the resistance heater and heat sink compound, were also supplied by NASA-
LaRC. The carbon fiber-epoxy matrix composites were prepared and the thermocouples (Type K) were fabricated by NASA-LaRC personnel. The data acquisition hardware and software used in taking temperature, voltage, and current measurements had been previously programmed. Therefore, only the assembly of the experimental apparatus remained to be completed, with the details given next.

4.1.1.1 Experimental Set-Up Assembly

The one-dimensional experimental apparatus involved the following procedure:

1) Measure the thickness and diameter of two composite samples (Samples 1 and 2), and the height and diameter of two copper blocks.

2) Coat one surface of a copper block with a thin layer of silicon heat sink compound. Make sure the compound is smooth and evenly distributed. A flat edge the width of the sample is useful to apply the coating with.

3) Place (2) thermocouples on top of the copper block layered with the heat sink. The junction should be in the center of the samples and the two wires should be parallel to each other and equidistance approximately 0.635 cm from the center of the second axis. To keep the thermocouples in place, tape them down either to the table or to the sides of the sample. Be sure to number the thermocouples so that their position can be recorded (see Fig. 4.1).

4) Coat one surface of Sample 1 with a thin layer of silicon heat sink compound. Again, be sure the compound is smooth and evenly distributed. Carefully place the composite sample (coated surface down) on top of the copper block over the thermocouples (see Fig. 4.2). Do not slide the composite sample on the block or
Figure 4.1. Position of Thermocouples (T/C's) on Copper Block for the One-Dimensional Experimental Design.

Figure 4.2. Sample 1 Placed on Top of the Copper Block for the One-Dimensional Experimental Design.
the thermocouples will be moved. Make sure that the contact is good.

5) Coat the other side of Sample 1 and again, place two thermocouples at this surface in the same manner as discussed previously.

6) Apply silicon grease to the heater on one side and place it on top of Sample 1. Be sure the heater is placed symmetrically over the sample so the same magnitude of heat flux is being distributed (see Fig. 4.3).

7) Coat the exposed top surface of the heater with the heat sink compound as before and place two more thermocouples at this surface, as described previously.

8) Coat Sample 2 (of approximately the same thickness as Sample 1) with silicon grease and place it on top of the exposed heater surface, over the thermocouples.

9) Coat the opposite side of Sample 2, place two more thermocouples as before on the surface, and finally, place a coated copper block over the composite sample (see Fig. 4.4).

10) Wrap the exposed sides of the composite material with rope insulation. Four pieces were used, two on each composite. If any thermocouple wire is exposed, tuck it inside of the insulation (see Fig. 4.5).

11) Carefully place the stacked samples between two plates and apply pressure evenly over the surface, taking care not to break the thermocouples. If thermocouples break, use less pressure. (Note, pressure was applied through threaded rods which ran through the corners of the plates).

Figure 4.4. Final Assembly of the Experimental Apparatus for the One-Dimensional Experimental Design with Eight Thermocouples (T/C's).
Figure 4.5. Insulation Wrapped Around the Heater and Composite Samples for the One-Dimensional Experimental Design.
4.1.1.2 Experimental Procedure

The experimental procedure consisted of applying a heat flux to a composite sample already at steady-state and then measuring the resulting temperatures using the data acquisition system. The process used for these experiments is given as follows:

1) Place the press containing the experimental set-up inside a temperature controlled oven. Connect the thermocouple wire to leads leading to a temperature compensator and data acquisition system. Heat the oven to the desired ambient temperature and allow the instrumented samples to equilibrate.

2) Activate the data acquisition system. Turn on the heater and simultaneously record temperature (mvolts) from thermocouples, and measured voltage and current to the heater. Turn the heater off after a pre-determined heating time and continue recording measurements until a pre-determined experimental time has elapsed.

3) If desired, the experiment can be repeated after the samples have again come to equilibrium with the oven temperature or the oven temperature can be changed and steps 1 and 2 can be repeated.

In these experiments, temperatures were recorded using eight Type K thermocouples at 0.5 second intervals up to a predetermined experimental time. All experiments were conducted at room temperature with the heater being applied for a predetermined heating time. (These times were determined using the optimal design criterion discussed previously). Experiments were conducted using three different voltage
inputs to the heater; 4.9V, 6.1V, and 7.3V. These resulted in maximum temperature rises of approximately 2°C, 3°C, and 4.5°C, respectively, over the initial temperature.

As mentioned, a one-dimensional heat conduction process through the composite sample was assumed. This assumption may introduce experimental error into the problem. However, to verify the validity of this assumption, the resistance to heat transfer was calculated both parallel and perpendicular to the direction of heat transfer. For one-dimensional heat conduction to be assumed, the parallel resistance should be much smaller than the perpendicular resistance, indicating that most of the heat will be conducted in one direction. To calculate the resistance in the direction of heat transfer, where only conduction through the sample is considered, the following equation was used:

$$R_{\text{cond}} = \frac{L_s}{k_{x-\text{eff}}A_x} \quad (4.1)$$

where $A_x$ is the cross-sectional area normal to the direction of heat transfer, $k_{x-\text{eff}}$ is the effective thermal conductivity parallel to the direction of heat transfer and $L_s$ is the thickness of the sample. For the resistance perpendicular to the direction of heat transfer, both conduction through the insulation material and convection with the air must be considered. The convective resistance is given as

$$R_{\text{conv}} = \frac{1}{hA} \quad (4.2)$$

where $h$ is the convective heat transfer coefficient. As an extreme case, this resistance was calculated using a $h$ of 10 W/m²°C. This indicates that heat is lost through the insulation by convection to the surrounding air. Since the experiments were conducted
at room temperature, this $h$ value is a good approximation for natural convection situations, as may be the case in this experiment. A thermal conductivity of 0.05 W/m°C was assumed for the insulation material used.

When performing these calculations, it was found that the resistance parallel to the direction of heat transfer is 7.3 °C/W while the resistance normal to this direction is 220 °C/W. Since the perpendicular resistance is much larger than the parallel resistance, the one-dimensional heat conduction assumption is valid.
Chapter 5

Results and Discussion

This chapter focuses on the results obtained for the optimal experimental design procedure for both the one-dimensional and two-dimensional analyses. In both cases, the experimental parameters were optimized using the technique described in Section 3.3. The thermal property estimates, effective thermal conductivity perpendicular to the fibers and effective volumetric heat capacity, obtained for the IM7 graphite fiber - Bismaleimide epoxy matrix composite are also discussed. These thermal properties were estimated using both the parameter estimation program, MODBOX, which requires an exact temperature solution and the finite element software, EAL, where the temperature solution is calculated numerically. In both cases, the properties were estimated using the modified Box-Kanemasu method described in Section 3.2.

The first and second sections of this chapter discuss the optimal experimental results obtained for the one-dimensional analysis and the estimated thermal properties found utilizing this design, respectively, while the last section discusses the optimal experimental results obtained for the two-dimensional configurations.
5.1 Results Obtained for the One-Dimensional Analysis (Isotropic Composite Material)

The thermal properties estimated for the one-dimensional analysis include the effective thermal conductivity perpendicular to the fiber axis, or the isotropic thermal conductivity, and the effective volumetric heat capacity. As mentioned in Section 3.2, measured temperatures were required for this estimation procedure; therefore, experiments had to be conducted. The next subsections discuss the results obtained for the optimization procedure used to determine the optimal experimental parameters utilized in these experiments. This includes an analysis of the sensitivity coefficients and the determination of the following experimental parameters: the heating time of the uniform heat flux, the temperature sensor location, and the total experimental time.

5.1.1 One-Dimensional Optimal Experimental Design

The minimization procedure used in this analysis to estimate the effective thermal properties is the Box-Kanemasu method. This method requires both measured and experimental temperatures. The experiments used to obtain the measured temperatures were optimized to provide more accurate property estimates. The optimization technique selected in this study, as discussed in Section 3.3, maximizes the determinant of the product of the dimensionless sensitivity coefficients and their transpose. Therefore, the first step in the optimization procedure is to calculate and analyze the sensitivity coefficients for each property. These coefficients are discussed next.
5.1.1.1 Sensitivity Coefficient Analysis

The first step in the optimization procedure was to calculate and plot the sensitivity coefficients. Recall that these coefficients are the derivatives of the temperature with respect to the unknown thermal properties and indicate the sensitivity of the temperature response due to changes in the parameters. In order for the thermal properties to be independently and accurately estimated, these coefficients should be large in magnitude (on the order of the temperature rise) and linearly independent. If the sensitivity coefficients are small, not enough information is available for the estimation procedure and if linear dependence exists between them, the parameters cannot be independently estimated. It is important to note, however, that the sensitivity coefficients may be linearly dependent over one range but independent over a different range. Knowing these ranges will help optimize the physical experiment.

The dimensionless sensitivity coefficients for the isotropic analysis are given by Eqs. (3.52-55). Figures 5.1 and 5.2 show the dimensionless sensitivity coefficients for the effective thermal conductivity \( \tilde{k}_{x_{\text{eff}}} \) and effective volumetric heat capacity \( \tilde{c}_{x_{\text{eff}}} \), respectively, at various positions within the composite. In Fig. 5.1, it is seen that after a dimensionless time of approximately three, all of the coefficients converge to a constant value. This indicates that temperature measurements taken beyond this dimensionless time supply little additional information for the estimation of \( k_{x_{\text{eff}}} \). This same result also occurs for the effective volumetric heat capacity sensitivity coefficients (Fig. 5.2). Here, after a dimensionless time of approximately three, the coefficients converge to zero. To
Figure 5.1. Transient Effective Thermal Conductivity Sensitivity Coefficients with the Heat Flux, $q(t)$, Applied for the Entire Experimental Time for Various $x^*$ ($x/L_*$) Locations.
Figure 5.2. Transient Effective Volumetric Specific Heat Sensitivity Coefficients with the Heat Flux, $q_x(t)$, Applied for the Entire Experimental Time for Various $x^* (x/L_x)$ Locations.
more accurately estimate $C_{\text{eff}}$, the majority of the temperature measurements should be taken over the dimensionless time range of zero to three, where the magnitude of the sensitivity coefficients is largest. It is apparent from these figures that the coefficients with the largest magnitude occur at a dimensionless $x^*$ (defined as $x/L_x$) location of zero. This position corresponds to the heated surface in this analysis. However, it is also evident that the $X_{k_{-\sigma}}$ have a larger magnitude than those for $X_{C_{\sigma}}$. This indicates that the temperature data provides more information about $k_{\text{eff}}$ than it does for $C_{\text{eff}}$, and therefore, the estimates of $k_{\text{eff}}$ will be more accurate than those for $C_{\text{eff}}$.

It should be noted that the sensitivity coefficients in Figs. 5.1 and 5.2 were calculated with the heat flux applied for the entire duration of the experiment. Because the volumetric heat capacity coefficients approach zero, it suggests that a better scheme may consist of applying the heat flux for a finite duration instead of for the entire experimental time. This confirms that observing the sensitivity coefficients can give insight into the accuracy of the experimental design.

As mentioned, if the sensitivity coefficients are linearly dependent, the thermal properties are correlated and cannot be simultaneously estimated. One way to determine if linear dependence exists is to plot the ratio of the sensitivity coefficients, as shown in Fig. 5.3 for an $x^*$ location of zero. In this figure, the ratio was plotted between the dimensionless time range of zero to three. (After this range, the volumetric heat capacity sensitivity coefficients converge to zero and the ratio becomes insignificant). If a constant curve occurs, the coefficients are linearly dependent. However, as evident from Fig. 5.3,

Figure 5.5. Maximum Dimensionless Determinant Curve, $D_{max}$, Used to Determine the Dimensionless Optimal Heating Time, $t_{h, opt}$.
For this study, the thickness of the sample, \( L_x \), was 6.78 mm. However, to determine \( \alpha_x \), \( k_{x,\text{eff}} \) and \( C_{\text{eff}} \) are required, which are the unknown parameters being estimated. Therefore, the actual heating time can be estimated by using previous estimates of \( k_{x,\text{eff}} \) and \( C_{\text{eff}} \) of other similar carbon-epoxy composite materials. The previous estimates used in this study were obtained from Scott and Beck (1992a). Using these values, the optimal heating time was calculated to be approximately 180 seconds. This value can be updated by conducting the experiments, obtaining new estimates for \( k_{x,\text{eff}} \) and \( C_{\text{eff}} \), recalculating the heating time using these new estimates, and repeating the process in an iterative procedure until the thermal properties no longer vary. However, as mentioned, a flat peak exists between heating times of 2.0 and 2.5. Therefore, the optimal heating time does not have to be precise to obtain the most accurate thermal property estimates.

5.1.1.3 Optimal Temperature Sensor Location

Next, the optimal temperature sensor location was determined by plotting the determinant as a function of heating time for various sensor locations (Fig. 5.6). It was found that the determinant is maximized when the sensor is located at the heated surface \((x^+ = 0.0)\). This result is consistent with the sensitivity coefficients shown in Figs. 5.1 and 5.2, where the coefficients with the largest magnitude occurred at the heated surface. Note that by placing additional thermocouples at other positions within the composite will be redundant and will not supply more information for the estimation procedure.
Figure 5.6. Determination of the Optimal Temperature Sensor Location, $x^* (x/L_a)$. 
5.1.1.4 Optimal Experimental Time

The last parameter that was determined was the optimal experimental time. In order to see the effect of added data to the value of the determinant, $D^+$, the determinant was calculated from Eqs. (3.42) and (3.43) using the optimal heating time and sensor location previously found, but without averaging the integral contained in Eq. (3.43) over time. The results are shown in Fig. 5.7; here, it is evident that after a dimensionless time of approximately five, the determinant no longer changes significantly. This implies that after this dimensionless time, the temperature is reaching its initial state and little additional information is being provided for the estimation of the thermal properties. Therefore, the experiments can be concluded after a dimensionless time, $t_N^+$, of approximately five. Note that this is a conservative choice, however, and from Fig. 5.7, a smaller value, such as four, could have also been chosen. Again, the actual experimental time that $t_N^+$ represented was found by using the definition of $t_N^+$ (Eq. (3.44c)) and the previous estimates for $k_{x,\text{eff}}$ and $C_{\text{eff}}$ (Scott and Beck, 1992a). The experimental time calculated for this study was approximately 8 minutes. However, when examining the measured temperatures obtained from the experiments, it is seen that its initial state (a dimensionless value of zero) is reached after approximately five to six minutes, indicating that no new temperature information is being supplied. This corresponds to a dimensionless experimental time of three to four, again showing that a $t_N^+$ of five is a conservative value.
Figure 5.7. Modified Dimensionless Determinant, $D^*$, Used to Determine the Dimensionless Optimal Experimental Time, $t_N^*$. 
5.1.1.5 Sensitivity Coefficient Using the Optimal Experimental Parameters

To illustrate the optimal results, the sensitivity coefficients were re-calculated using these optimal experimental parameters and are shown in Fig. 5.8 at an $x^+$ location of zero. As one can see from this figure, more information used to estimate the thermal properties is supplied when the heater is applied for the determined optimal heating time rather than over the entire experimental time. This occurs because when the heater is applied for the entire duration, steady-state values are reached early on and information is no longer available for the estimation of $C_{eff}$. However, when turning the heater off during the experiment, a new transient response is introduced which results in additional temperature information for the estimation procedure.

5.1.2 Estimation of Thermal Properties for Isotropic Materials

The thermal properties, effective thermal conductivity perpendicular to the fiber axis and effective volumetric heat capacity, were estimated for an IM7 graphite fiber - Bismaleimide epoxy matrix composite both analytically, using the program MODBOX, and numerically, utilizing the finite element software, EAL. In both cases, the modified Box-Kanemasu method was used in the estimation procedure. The properties were estimated using both experimental data and numerical and exact solutions so that the two could be compared and verification of the accuracy of EAL could be made. The estimated thermal properties obtained for the one-dimensional analysis are given in the following two subsections. In this analysis, the optimal experimental design previously determined was utilized to record the experimental temperatures required.
Figure 5.8. Transient Dimensionless Sensitivity Coefficients, $X_{k,e}^*$ and $X_{C,e}^*$, at an $x^* (x/L_x)$ Location of 0.0 Using the Dimensionless Optimal Heating Time, $t_{k,opt}^*$. 
5.1.2.1 Estimated Thermal Properties Using an Exact Temperature Solution

The thermal properties, effective thermal conductivity perpendicular to the fiber axis and effective volumetric heat capacity, were estimated from an exact temperature model (Eqs. (3.8) and (3.9)) using the sequential, non-linear estimation program MODBOX. The estimates that were obtained for three repeated experiments are given in Table 5.1, along with their 95% confidence intervals. The confidence intervals for each estimated parameter, \( b_i \), were approximated by

\[
b_i \pm \left( \frac{P_{ii}}{(N - p)} \right)^{1/2} t_{1-\alpha/2}(N - p)
\]

where \( p \) is the number of parameters estimated, \( N \) is the number of data points measured, \( P_{ii} \) is the \( i \)th diagonal of the \( P \) matrix (Eq. (3.37)) which represents the variance of the parameter, \( S \) is the sum of the squared residuals, and \( t_{1-\alpha/2}(N-p) \) is the value of the \( t \) distribution for \((1-\alpha/2)\) confidence region and \((N-p)\) degrees of freedom (Beck and Arnold, 1977). In this study, a considerable number of temperature measurements were taken and used in the estimation procedure; therefore, only a slight variance in the estimates would be expected. This is in fact the case, as shown by the small confidence intervals for each property estimate in Table 5.1. It is also seen that the confidence intervals for \( k_{x\text{-eff}} \) were smaller than those for \( C_{\text{eff}} \). This implies that the estimates for \( k_{x\text{-eff}} \) are more accurate than for \( C_{\text{eff}} \). This is consistent with the sensitivity coefficients (Figs. 5.1 and 5.2), where the magnitude of the effective volumetric heat capacity sensitivity coefficients is less than that of the effective thermal conductivity. Therefore, the
estimation of $C_{\text{eff}}$ is more sensitive to experimental errors and will not be as accurate as estimates for $k_{\text{eff}}$.

The mean value of the thermal property estimates was also calculated, along with its 95% confidence interval. In this case, the 95% confidence intervals were obtained from

$$\overline{b}_i \pm \frac{t_{\alpha/2}}{\sqrt{N}} s$$

where $\overline{b}_i$ and $s$ are the mean and standard deviation of the estimate, respectively, $N$ is the number of data points used, and $t_{\alpha/2}$ is the value of the $t$ distribution with $(N-1)$ degrees of freedom and $\alpha/2$ confidence region (Walpole and Myers, 1978). As seen in Table 5.1 for all three experiments, the property estimates fall within the 95% confidence intervals of the mean values.

To determine how accurately the calculated temperatures matched the measured temperatures, the Root Mean Square (RMS) error was also computed where

$$RMS = \sqrt{\frac{\sum_{i=1}^{n} (Y_i - T_i)^2}{N}}$$

Here, $T_i$ and $Y_i$ are the calculated and measured temperatures, respectively, at the $i$th time step, and $N$ is the total number of temperature measurements. The RMS values were calculated two different ways. First, the measured temperatures for each individual experiment were compared with calculated values using the thermal properties estimated for that experiment; these values are indicated by $RMS_i$ in Table 5.1. The RMS values
were then determined using the experimental temperatures and calculated temperatures determined using the mean thermal property values (also shown in Table 5.1); these values are indicated by $RMS_m$.

To demonstrate the validity of the estimated properties, the calculated temperatures obtained using the estimated effective thermal conductivity and effective volumetric heat capacity values were compared with the measured temperatures for Experiment 3 in Fig. 5.9. As one can see, there was very good agreement between the calculated and measured temperatures which indicates that the estimated values are reliable.

The significance of the $RMS_m$ values, or the errors resulting from using the mean

Table 5.1  Estimated effective thermal conductivity, $k_{x_{eff}}$, and volumetric heat capacity, $C_{eff}$, from Experiments 1, 2, and 3, using exact temperature solutions along with the Root Mean Square error calculated from individual and mean thermal property estimates ($RMS_I$ and $RMS_M$).

Figure 5.9. Calculated and Measured Temperature (T) Profiles for Exp. 3
thermal property estimates, was demonstrated by plotting the temperatures calculated using the mean thermal property estimates against each set of experimental data in Fig. 5.10. From this figure, it is evident that in each case, the calculated temperatures closely match the measured temperatures. Furthermore, in comparing Table 5.1 with Fig. 5.10, the slight under prediction of temperature in Experiment 2 and the slight over prediction of temperature in Experiment 3 can be attributed to the small differences between the individual estimated effective thermal conductivity and the mean value, with the thermal conductivity estimate for Experiment 2 being slightly under the mean and the value for Experiment 3 being slightly over the mean value. However, even with these slight variations, the $RMS_u$ as a percentage of the maximum temperature rise for each run was less than 0.5%, as shown in Table 5.1. This indicated that for all three cases, the mean values provided reasonable estimates of the true thermal property values. It also indicates that the model used to describe this heat conduction process, as well as the experimental design used to obtain the temperature data, are satisfactory.

The estimate obtained for the effective thermal conductivity was compared with results obtained at NASA-LaRC using a cut-bar comparative apparatus (Dynatech, model number TCFCM-N4). This device operates by supplying a steady state heat flow in one dimension across the composite sample and the same heat flow through a known standard material. The temperature difference across the standard material allows for the determination of the heat flux, while the temperature difference across the sample gives the value of the effective thermal conductivity. Using this apparatus, experiments were conducted on three composite samples that were the same type studied in this analysis.
Figure 5.10. Temperature (T) Profiles for Both Experimental and Calculated Measurements Using Average Thermal Property Estimates.
The average result obtained for these three composite samples for the thermal conductivity was $0.473 \pm 0.038 \text{ W/m}^\circ\text{C}$. This is approximately a 9% difference from the average $k_{x-eff}$ estimated in this study. However, these experiments were conducted at 40°C, whereas in this investigation, the experiments were performed at room temperature; therefore, an exact comparison cannot be made.

5.1.2.2 Estimated Thermal Properties Using a Numerical Temperature Solution

The thermal properties were also estimated using EAL, where the temperatures were calculated numerically. Again, the modified Box-Kanemasu estimation technique was employed. The results obtained for the estimated effective thermal conductivity perpendicular to the fibers and effective volumetric heat capacity for the three experiments are shown in Table 5.2, along with the % difference from the estimates obtained using the exact temperature solutions. This % difference is defined as

$$\frac{(\beta_{EAL} - \beta_{Exact})}{\beta_{Exact}} \times 100\%$$  (5.5)

where $\beta$ is the parameter being estimated. As one can see from Table 5.2, the estimates found using EAL closely match those obtained using exact temperature models with a percent difference of less than 1% occurring. The effective volumetric heat capacity estimates had the largest percent differences and resulted because this property is more difficult to estimate than the thermal conductivity. As mentioned, this occurs because the magnitude of the sensitivity coefficients for $C_{eff}$ are less than those for $k_{x-eff}$, causing the estimation of $C_{eff}$ to be more sensitive to experimental errors and to not be as accurately
Table 5.2  Estimated effective thermal conductivity, $k_{x,\text{eff}}$, and volumetric heat capacity, $C_{\text{eff}}$, from Experiments 1, 2, and 3, using numerical temperature solutions (from EAL) along with the % difference from estimates calculated using exact temperature models.

estimated as $k_{x,\text{eff}}$.

From Table 5.2, it can be concluded that the estimated parameters found using the finite element software, EAL, are quite accurate and provide reasonable estimates of the true thermal property values.

To verify the accuracy of the temperature solution found using EAL, based on the estimated parameters, the temperature profile was plotted along with the temperature distribution calculated using an exact analytical solution, as shown in Fig. 11. Here, it is seen that the two curves are essentially equal, and therefore, using EAL provides reliable temperatures. This is also shown by calculating the $RMS$ value, as given in Eq. (5.4), where $Y_i$ is the temperature calculated from an exact solution and $T_i$ is the temperature calculated from EAL. For the experiment shown in Fig. 5.11, the $RMS$ value was only 0.27%, again indicating the accuracy of EAL.
Figure 5.11. Temperature (T) Profile Using Both an Exact Solution and EAL.
5.1.2.3 Sequential Parameter Estimates

Viewing the sequential parameter estimates can give insight on the validity of the mathematical model used to represent the heat conduction process and the resulting experimental design. The sequential estimates for the converged values of the thermal conductivity and volumetric heat capacity for Experiment 3 are plotted in Fig. 5.12; these estimates were obtained using exact mathematical models. From this figure, it is evident that each estimate fluctuated greatly towards the beginning of the experiment. This occurred because the heat flux had just been activated and not enough temperature information was available for the estimation procedure. However, after approximately 400 seconds which corresponds to a dimensionless experimental time of approximately three, the estimates for both the thermal conductivity and volumetric heat capacity are constant, indicating that additional data would have provided little additional information for the estimation of these parameters. This also indicates that the heat conduction model is satisfactory and the optimal experimental time of five is indeed a conservative value, as discussed previously.

5.2 Results Obtained for the Two-Dimensional Analysis (Anisotropic Composite Material)

For the two-dimensional analysis, three properties can be estimated simultaneously: effective thermal conductivity perpendicular to the fiber axis \(k_{x\text{-eff}}\), effective thermal conductivity parallel to the fiber axis \(k_{y\text{-eff}}\), and effective volumetric heat capacity \(C_{\text{eff}}\).
Figure 5.12. Sequential Estimates for Effective Thermal Conductivity, $k_{x\text{-eff}}$ (W/m°C) and Effective Volumetric Heat Capacity, $C_{\text{eff}}$ (MJ/m$^3$°C).
In this investigation, these thermal properties are not estimated; however, the experimental designs used to obtain the temperature data required for the estimation procedure are optimized, as in the one-dimensional analysis. Discussed next are the results obtained for these optimal experiments.

5.2.1 Two-Dimensional Optimal Experimental Designs

Two different two-dimensional experimental configurations were analyzed in this study, each containing different boundary conditions. The experimental parameters for both configurations were optimized by maximizing the determinant of the product of the sensitivity coefficients and their transpose. The maximum determinant values for both configurations were then compared to determine which design would be the best choice; the configuration with the largest determinant value would give the most accurate property estimates. Recall that both configurations had a uniform heat flux imposed over a portion of one boundary with the remainder of the boundary insulated. In addition, Configuration 1 had known, constant temperatures at the remaining three boundaries, while the second configuration had a constant temperature at the boundary opposite to the flux boundary and insulated conditions at the remaining two boundaries. (For clarity, these configurations are again shown in Figs. 5.13 and 5.14). Therefore, in addition to the optimal parameters determined for the one-dimensional case, the optimal position of the heat flux was also determined for both configurations. Because of the different boundary conditions used, the optimal experimental parameters for each design will not be identical. For example, the portion of the boundary that the heat flux should cover
Figure 5.13. Experimental Set-up Used for Configuration 1 in the Estimation of the Effective Thermal Conductivities in Two Orthogonal Planes.

Figure 5.14. Experimental Set-up Used for Configuration 2 in the Estimation of the Effective Thermal Conductivities in Two Orthogonal Planes.
will vary between the two configurations, and therefore, must be determined for each individual design. The optimal parameter results for both configurations are discussed in the following two subsections. These include the optimal heating time, optimal temperature sensor location, optimal heat flux position, and optimal experimental time. In addition, the sensitivity coefficients for both configurations are analyzed for insight into the experimental design and to determine if possible correlation exists between the thermal properties. The two configurations are then compared to determine which will provide more accurate property estimates, and finally, the last subsection discusses the optimal values for various composite dimension \((L_{xy})\) and thermal conductivity \((\kappa_{xy})\) ratios.

5.2.1.1 Optimal Experimental Parameters Determined for Configuration 1

Using Configuration 1, it was desired to select the experimental parameters which maximize the sensitivity of the temperature with respect to all of the unknown thermal properties. The same technique was used as in the one-dimensional optimization procedure, only now, the required maximum temperature value \((T_{max}')\) was redefined as the temperature attained at steady state. This \(T_{max}'\) was used because it represents the actual maximum temperature that could be reached for this particular design.

To perform the optimization procedure, the temperature solutions and sensitivity coefficients require predetermined values for \(L_{xy}(L_x/L_y)\) and \(\kappa_{xy}(\kappa_{xy}/k_{x-eff})\). The value chosen for \(L_{xy}\) in this analysis corresponds to the size \((0.49 \text{ cm} \times 10.16 \text{ cm})\) of an existing composite sample that can be used in the experiments to determine the temperatures needed in the estimation procedure, while the value for \(\kappa_{xy}\) was taken from previously
measured effective thermal conductivities parallel and perpendicular to the fiber axis of similar carbon-epoxy composite samples (Loh and Beck, 1991). The specific values used were $L_{xy} = 0.048$ and $\kappa_{xy} = 7$. However, to allow the optimization procedure to be applicable to other composite dimensions or effective thermal conductivity ratios, optimal experimental parameters were also calculated for all possible combinations of $L_{xy}$’s equal to 0.5 and 1.0, and $\kappa_{xy}$’s equal to 1 and 1/7. This results in a total of nine combinations. The results for the combination discussed above ($L_{xy} = 0.048$ and $\kappa_{xy} = 7$) will be examined the most thoroughly, however, since these are the actual conditions of an existing composite sample that can later be utilized in the experimental designs to estimate the thermal properties.

In performing the optimization procedure for $L_{xy} = 0.048$ and $\kappa_{xy} = 7$, five parameters were optimized: the dimensionless portion of the boundary that the heat flux is applied, $L_p^+$, the dimensionless location $(x_s^+, y_s^+)$ of the temperature sensor, the dimensionless heating time, $t_h^+$, and the dimensionless experimental time, $t_e^+$. Note that the optimal experimental time is not as important as the other four parameters. Therefore, the optimal procedure used to determine $x_s^+, y_s^+, L_p^+, t_h^+$ did not take into account the optimization of $t_e^+$ (this value was determined last).

The most accurate way to determine the optimal value for each parameter is to differentiate the determinant given in Eq. (3.45) with respect to each of the experimental parameters and set it equal to zero, resulting in four equations and four unknowns. These equations can then be solved simultaneously, allowing for the desired optimal parameters to be determined. However, this method is not practical due to the complexity of the
equations involved. Therefore, an iterative scheme was developed where a program was used to vary each of the four parameters individually (excluding \( t^+_n \)). This iterative procedure consists of two phases; the first phase includes determining the general range of the optimal values, while the second phase narrows this range to determine the optimal experimental parameters more precisely. In phase one, the following procedure was used:

1) Fix \( x^+_s, y^+_s, \text{ and } L^+_p, l \) to their starting values (0.0, 0.0, and 0.1, respectively).

2) Vary \( t^+_h \) from 0.05 to 5.0 by 0.05. For each \( t^+_h \), calculate the determinant, \( D^+ \), as a function of time, \( t^+ \).

3) Determine the maximum determinant value, \( D_{\text{max}}^+ \), for each of the determinant curves generated in step 2 for each \( t^+_h \).

4) Compare the maximum determinant values found for each \( t^+_h \) and record the one with the largest magnitude, along with its corresponding heating time, \( t^+_h \).

5) Holding \( y^+_s \) and \( L^+_p, l \) constant at their original values, vary \( x^+_s \) and repeat steps 2 through 4. Note, \( x^+_s \) was varied from 0.0 to 1.0 by 0.1 increments.

6) After the \( x^+_s \) loop is completed, change \( y^+_s \) to its new value (increment the previous value by 0.1) holding \( L^+_p, l \) fixed and again repeat steps 2 through 5. Note, \( y^+_s \) was varied from 0.0 to 1.0 by 0.1 increments.

7) Finally, change \( L^+_p, l \) to its new value (increment the previous value by 0.1) and repeat steps 2 through 6 in the designated order.

This procedure then provides a maximum determinant value for all combinations of \( x^+_s, y^+_s \) and \( L^+_p, l \), with the corresponding \( t^+_h \). From this data, the general region of the actual
maximum determinant can be determined. Phase two then involves refining the grid sizes for the parameters in this region to determine the $D_{\text{max}}$ location more precisely. Since there is more than one parameter that can vary, the procedure is more complex than the one-dimensional analysis, and must be iteratively updated.

5.2.1.1.1 Optimal Temperature Sensor Location on the $x^+$ Axis

The first optimal parameter determined was the temperature sensor location along the $x^+$ direction. Recall from the experimental configuration (Fig. 5.13) that this is the direction parallel to the heat flow. From the one-dimensional analysis, it was determined that the optimal location to place the sensor was at the heated surface. Therefore, the same result would be expected for the two-dimensional analysis. This was in fact the case, with the maximum determinant always occurring at a $x_s^+$ location equal to zero (or at the heat flux boundary) for all combinations of $L_{p,1}^+$ and $y_s^+$. This result is reasonable because the maximum determinant occurs when the sensitivity coefficients are the largest, or when the greatest temperature variation occurs. Since the temperature of the composite is initially at a dimensionless value of zero, then at the boundary where the uniform heat flux is applied would be the location where the largest temperature gradient in the $x^+$ direction would occur.

5.2.1.1.2 Optimal Temperature Sensor Location on the $y^+$ Axis

The next parameter chosen to optimize was the sensor location along the $y^+$ axis. After calculating the maximum determinant value for each $x_s^+, y_s^+$, and $L_{p,1}^+$ combination
and determining that the optimal sensor location along the $x^+$ axis was at the heated surface, it was found that the true maximum determinant (the largest value of all of the maximum determinants for each combination) was in the general region of $y_s^+=0.1$, $L_{p,i}^+=1.0$, and $t_h^+=1.35$. However, it should be noted that for all $L_{p,i}^+$ locations, the maximum determinant always occurred at $y_s^+$ equal to 0.1 with a $t_h^+$ of approximately 1.35. Using the optimal values of $L_{p,i}^+=1.0$ and $t_h^+=1.35$, the grid size for $y_s^+$ was refined around 0.13, using a range from 0.05 to 2.0, to determine the optimal $y_s^+$ location more precisely. Using this refined range, the maximum determinant occurred at a new $y_s^+$ location of 0.13, as shown in Fig. 5.15, where the maximum determinant values for various $y_s^+$ locations are plotted (again, using $L_{p,i}^+=1.0$ and $t_h^+=1.35$). It should be noted that when the heat flux is applied across the entire boundary ($L_{p,i}^+=1.0$), the problem becomes symmetric. Therefore, a $y_s^+$ of 0.87 would also be an optimal location, resulting in the same maximum determinant value as for $y_s^+$ equal to 0.13.

5.2.1.1.3 Optimal Heating Time

The next parameter determined was the optimal heating time. Using the optimal location for $y_s^+$ found above of 0.13 and the corresponding $L_{p,i}^+$ of 1.0, the dimensionless heating times were varied around the previously determined optimal value of $t_h^+=1.35$ (ranging from 0.05 to 2.0). The maximum determinant then occurred at a new $t_h^+$ of 1.4, as seen in Fig. 5.16, where the maximum determinants are plotted for various $t_h^+$ values. As mentioned, since more than one parameter can vary, determining the optimal
Figure 5.15. Maximum Determinant, $D_{\text{max}}^+$, for Various Locations Along the $y^+$ ($y/L_y$) Axis Calculated Using the Optimal Values of $x_i^+=0.0$, $L_{p,l}^+=1.0$, and $t_h^+=1.35$. 
Figure 5.16. Maximum Determinant, $D_{\text{max}}^+$, for Various Heating Times, $t_h^+$, Calculated Using the Optimal Values of $x_i^*=0.0$, $L_{\tau,1}^+=1.0$, and $y_s^+=0.13$. 
parameters for the actual maximum determinant becomes an iterative process. Therefore, since a new $t_h^+$ was determined, the $y_s^+$ values were again varied over the same range (0.05 to 2.0) using the new heating time of 1.4 (and the previously calculated optimal value for $L_{p,i}^+$ of 1.0) to see if its optimal value changed. However, as seen in Fig. 5.17, changing the heating time from 1.35 to 1.4 did not alter the optimal $y_s^+$ value of 0.13.

5.2.1.1.4 Optimal Heat Flux Location, $L_{p,i}^+$

Using the optimal parameters determined of $x_s^+=0.0$, $y_s^+=0.13$, and $t_h^+=1.4$, the position of the heat flux, $L_{p,i}^+$, was then varied from 0.6 to 1.0 to see if the previous optimal location of $L_{p,i}^+=1.0$ changed when using these new $y_s^+$ and $t_h^+$ values. This result is shown in Fig. 5.18. As seen in this figure, the maximum determinant occurred at a $L_{p,i}^+$ location of 1.0, as obtained previously. This indicates that the optimal design for Configuration 1 consists of having the heat flux applied over the entire boundary. However, it is evident that the curve in Fig. 5.18 is rather flat when the heater is applied over 70 to 100% (0.70 to 1.0) of the boundary, and therefore, any value in this range could be used to obtain the same accuracy in the property estimates.

5.2.1.1.5 Optimal Experimental Time

Finally, the last parameter determined was the optimal dimensionless experimental time, $t_h^+$. This was calculated using the same procedure as for the one-dimensional analysis, where the dimensionless determinant, $D^+$, was calculated from Eqs. (3.42) and (3.43) using the optimal parameters determined for $x_s^+$, $y_s^+$, $L_{p,i}^+$, and $t_h^+$, but without
Figure 5.17. Maximum Determinant, $D_{max}^+$, for Various Locations Along the $y^+$ ($y/L_p$) Axis Calculated Using the Optimal Values of $x_s^+=0.0$, $L_p^+=1.0$, and $t_h^+=1.35$ (Second Iteration).
Figure 5.18. Maximum Determinant, $D_{\text{max}}^*$, for Various Heater Locations, $L_{p,1}^*$ ($L_p/L_x$), Calculated Using the Optimal Values of $x_1^* = 0.0$, $y_x^* = 0.13$, and $t_k^* = 1.4$. 
averaging the integral contained in Eq. (3.43) over time. The results are shown in Fig. 5.19; here, it is evident that after a dimensionless time of approximately 4.0, the determinant no longer changes significantly. This implies that after this dimensionless time, the temperature is returning to its initial state (a dimensionless value of zero) and little additional or no information is being provided for the estimation of the thermal properties. Therefore, the experiments can be concluded after a dimensionless time, \( t_N^+ \), of approximately 4.0. Again, however, as in the one-dimensional case, this is a conservative choice, and a smaller value, such as 3.5, could have also been chosen.

5.2.1.1.6 Verification of the Optimal Temperature Sensor Location of the \( x^+ \) Axis

To verify the optimal location of the temperature sensor along the \( x^+ \) direction, for which a value of zero was determined, the dimensionless determinant was calculated using the optimal values for \( y_s^+ \), \( L_{p,t}^+ \), and \( t_h^+ \) for various \( x_s^+ \) locations. The results are plotted in Fig. 5.20 against dimensionless time. As seen from this figure, the maximum determinant occurred when the sensor was at the heated surface (\( x_s^+ = 0.0 \)), confirming the optimal result obtained for the \( x_s^+ \) location.

5.2.1.1.7 Maximum Determinant Using the Optimal Experimental Parameters

In summary, the above optimization procedure resulted in the following optimal experimental parameters for Configuration 1: \( x_s^+ = 0.0, y_s^+ = 0.13, L_{p,t}^+ = 1.0, \) and \( t_h^+ = 1.4 \). Using these optimal experimental parameters, the dimensionless determinant, \( D^+ \), was plotted versus dimensionless time, where a maximum of \( 5.36 \times 10^{-7} \) occurred, as shown
Figure 5.19. Modified Dimensionless Determinant, $D^+$, Used to Determine the Dimensionless Optimal Experimental Time, $t_N^+$. 
Figure 5.20. Determination of the Optimal Sensor Location on the $x^+ (x/L_x)$ Axis.
in Fig. 5.21. The reason why these determinant values are less than those obtained for the one-dimensional case is because $D^+$ is now a $3 \times 3$ determinant, as given in Eq. (3.45). Since the sensitivity coefficients are of the same order of magnitude for both the one-dimensional and two-dimensional cases, then multiplying three coefficients together, as required in the 2-D determinant, will result in smaller maximum determinant values than multiplying only two coefficient values, as in the 1-D determinant.

5.2.1.1.8 Temperature Distributions for Configuration 1

Using the optimal values for $x_s^+$ and $L_{p,*}$, temperature was plotted for various $y_s^+$ locations for four different dimensionless times: early (0.1), intermediate (two at 0.5 and 1.4), and steady state (4.0) (Fig. 5.22). Note that these temperature distributions were calculated with the heat flux applied for the entire experimental time, $t_N^+$. The desired optimal values occur when the determinant is a maximum, or when the sensitivity coefficients are the most sensitive to temperature changes. This typically occurs when the temperature gradient is large. As seen from this figure, at and near the optimal $y_s^+$ location of 0.13, the temperature gradient is steep with respect to $y_s^+$, and therefore, the sensitivity coefficients for $k_{p,eff}$ are expected to be large in magnitude. This steep gradient occurs because the composite sample is heated, however, the temperatures at the boundaries are held constant, resulting in a large temperature variation. However, it is also seen that the optimal $y_s^+$ location is not at the steepest temperature gradient. This results because the maximum determinant occurs when the product of the sensitivity coefficients for all three parameters is the largest in magnitude, which is not necessarily
Figure 5.21. Dimensionless Determinant, $D^*$, Calculated Using the Optimal Experimental Parameters of $x^*_t=0.0$, $y^*_t=0.13$, $L_P^*_t=1.0$, and $t_h^*_t=1.4$. 
Figure 5.22 Temperature ($T$) Distribution for Various $y^*$ Locations Calculated Using Four Different Experimental Times.
at the largest temperature gradient in the $y^+$ direction.

The temperature distribution was also calculated as a function of time using the optimal experimental parameters determined above (see Fig. 5.23). As shown in Fig. 5.23, the heat flux is terminated as the temperature approaches steady state ($t_h^+=1.4$). This is consistent with Fig. 5.22, where applying the heat flux for the dimensionless time of 1.4 results in temperatures close to the steady state temperatures attained at $t*=4.0$.

5.2.1.1.9 Sensitivity Coefficients Calculated Using the Optimal Experimental Parameters

Using the optimal experimental parameters determined, the dimensionless sensitivity coefficients for the three effective thermal properties, $k_{x\text{-eff}}, k_{y\text{-eff}},$ and $C_{\text{eff}}$, were calculated and plotted as a function of dimensionless time, as shown in Fig. 5.24. Here, it is seen that the sensitivity coefficients for $k_{x\text{-eff}}$ and $C_{\text{eff}}$ are relatively large in magnitude, being on the same order as the temperature rise, with the $k_{x\text{-eff}}$ coefficients being the largest. The sensitivity coefficients for $k_{y\text{-eff}}$ have the smallest magnitude of all three. It is also seen that after a dimensionless time of approximately four, all of the coefficients converge to zero, indicating that temperature measurements taken beyond this time supply little additional information for the estimation procedure. This result is consistent with the temperature distribution (Fig. 5.23), where its initial state was attained after this dimensionless time. Therefore, no new temperature information is being provided and the estimation procedure is complete. This result is also consistent with the determined optimal experimental time, where after a $t_\text{H}^+$ of 4.0, the determinant no longer varied.

Since the sensitivity coefficients for $k_{x\text{-eff}}$ have a larger magnitude than the
Figure 5.23. Temperature Distribution for Configuration 1 Calculated Using the Optimal Experimental Parameters of $x_s^*=0.0$, $y_s^*=0.13$, $L_{p,l}^*=1.0$, and $t_h^*=1.4$. 
Figure 5.24. Dimensionless Sensitivity Coefficients, $X_{k}$, $X_{y}$, and $X_{c}$, Calculated Using the Optimal Experimental Parameters of $x_{j}^{*}=0.0$, $y_{j}^{*}=0.13$, $L_{p,j}^{*}=1.0$, and $t_{h}^{*}=1.4$. 
coefficients for $k_{x_{eff}}$ and $C_{eff}$, it implies that the temperature data are supplying more information for the estimation of $k_{x_{eff}}$ than $k_{y_{eff}}$ and $C_{eff}$. As a result, the estimated values obtained for $k_{x_{eff}}$ can be regarded as the most accurate of the three parameters, resulting in the smallest confidence intervals.

As mentioned in the one-dimensional case, it is important to plot the sensitivity coefficients to see if they are correlated. If correlation occurs, the thermal properties cannot be estimated independently. From Fig. 5.24, it is evident that the $C_{eff}$ sensitivity coefficient, which changes from negative to positive values, is not correlated with either the $k_{x_{eff}}$ or $k_{y_{eff}}$ coefficients, which are always negative. However, this observation is not as apparent between the $k_{x_{eff}}$ and $k_{y_{eff}}$ sensitivity coefficients. If they are correlated, then only the ratio, $\kappa_{xy}$, can be estimated. Therefore, to test for possible correlation, the ratio of $X_{k_{x_{eff}}} / X_{k_{y_{eff}}}$ was calculated and plotted as a function of dimensionless time (Fig. 5.25). If a straight line occurs, the two parameters are correlated. However, as evident from Fig. 5.25, the line is far from linear, and therefore, $k_{x_{eff}}$ and $k_{y_{eff}}$ can be estimated simultaneously.

5.2.1.2 Optimal Experimental Parameters Determined for Configuration 2

Recall that Configuration 2 consisted of a uniform heat flux imposed over a portion of one boundary, with the remainder of the boundary insulated. The boundary opposite to the flux boundary was maintained at a known constant temperature, and the remaining two boundaries were insulated (Fig. 5.14). Again, for this configuration, it was
Figure 5.25. Sensitivity Coefficient Ratio, $X_{x,\text{eff}}^*/X_{y,\text{eff}}^*$, to Check for Correlation Between $k_{x,\text{eff}}$ and $k_{y,\text{eff}}$. 
desired to select the experimental parameters which maximize the sensitivity of the temperature with respect to all of the unknown thermal properties. Since the same composite samples will be used in the experiments for both Configurations 1 and 2, the result for a $L_{xy}$ of 0.048 and a $\kappa_{xy}$ of 7 (Loh and Beck, 1991) will again be the most thoroughly analyzed. However, as in the Configuration 1 case, all possible combinations of $\kappa_{xy}$ equal to 1 and $1/7$, and $L_{xy}$ equal to 0.048, 0.5, and 1.0 will also be performed. The same optimization procedure, as discussed in Section 5.2.1.1 for Configuration 1, was used and similar experimental parameters were optimized ($x_s^+, y_s^+, L_p, t_h^+, t_n^+$). These experimental parameter results are discussed next.

5.2.1.2.1 Optimal Temperature Sensor Location on the $x^+$ Axis

The first optimal experimental parameter determined was the temperature sensor location along the $x^+$ axis. Again, as in Configuration 1, the maximum determinant always occurred at a $x_s^+$ location equal to zero (or at the heated surface) for all combinations of $y_s^+$ and $L_p, t^+$. This occurs for the same reason as discussed in Section 5.2.1.1.1, where the largest temperature gradient in the $x^+$ direction occurs at the heated surface.

5.2.1.2.2 Optimal Temperature Sensor Location on the $y^+$ Axis and Heat Flux Position

The next parameters that were optimized were the sensor location along the $y^+$ axis and the position of the applied heat flux, $L_p, t^+$. After calculating the maximum determinant for each $x_s^+, y_s^+, L_p, t^+$ combinations, the true maximum determinant (the
largest value of all of the maximum determinants for each combination) was in the general region of $L_p,2^+=0.9$, $y_s^+=0.8$, and $t_h^+=1.55$. To determine the precise location of the actual maximum determinant, both the $L_{p,2}^+$ and $y_s^+$ grid sizes were refined around the previously obtained values of 0.9 and 0.8 respectively, ($L_{p,2}^+$ was varied from 0.84 to 0.92 and $y_s^+$ was varied from 0.6 to 0.9) while holding $t_h^+$ constant at 1.55. For each $L_{p,2}^+$ value, the maximum determinant was plotted as a function of the $y_s^+$ location in Fig. 5.26. As seen in this figure, the actual maximum determinant occurs at a $L_{p,2}^+$ of 0.89 and a corresponding $y_s^+$ location of 0.77. However, it is seen that the curve is fairly flat when $L_{p,2}$ is located between 0.88 to 0.9; therefore, any value within this range could be used for $L_{p,2}$ to improve the accuracy of the property estimates. Note that $L_{p,2}^+$ is different than $L_{p,1}^+$, as expected. If $L_{p,2}^+$ had equalled $L_{p,1}^+$ the heat flux would be applied over the entire boundary. Due to the insulated boundary conditions on the sides used in this configuration, the problem would reduce to one-dimensional heat conduction and $k_{y\text{-eff}}$ could no longer be estimated.

5.2.1.2.3 Optimal Heating Time

The next parameter optimized was the heating time. Setting $L_{p,2}^+$ and $y_s^+$ equal to their optimal values calculated in the above section, (0.89 and 0.77, respectively) the heating time was varied around its previously determined value of $t_h^+=1.55$ (from 1.45 to 1.65). At each heating time, the dimensionless determinant was calculated as a function of dimensionless time. A few of these determinant curves are shown in Fig. 5.27 for
Figure 5.26. Maximum Determinant, $D_{max}^+$, for Various $y^+_s (y/L_y)$ Locations and Heater Locations, $L_{p,2}^+ (L_{p,2}/L_y)$, Calculated at $x^+_s=0.0$.

$(L_{p,3})^+ = 0.86$
$(L_{p,3})^+ = 0.88$
$(L_{p,3})^+ = 0.89$
$(L_{p,2})^+ = 0.9$
Figure 5.27. Maximum Determinant, $D^*_{\text{max}}$, for Various Heating Times, $t_h^*$, Calculated Using the Optimal Experimental Parameters of $x^*_t=0.0$, $y^*_t=0.77$, and $L_{p.2}^*=0.89$. 

Dimensionless Determinant, $D^* \times 10^7$

Dimensionless Experimental Time, $(t_N)^*$
various heating times. The maximum determinant value of all of these curves occurred when the heating time was equal to 1.55. This is the same result obtained previously, and therefore, the optimal values calculated for $L_{p,2}^+$ and $y_s^+$, which were found using a $t_h^+$ of 1.55, do not have to be iteratively updated. Note, however, that the maximum determinants are practically equal for all heating times between 1.45 and 1.65. Therefore, using a $t_h^+$ of 1.55 does not have to be precise to provide the most accurate property estimates.

5.2.1.2.4 Optimal Experimental Time

Finally, the last parameter determined was the optimal dimensionless experimental time, $t_N^+$. This was calculated using the same procedure as in Configuration 1 (Section 5.2.1.1.5) with the modified dimensionless determinant results shown in Fig. 5.28. Here, it is evident that again, as in Configuration 1, after a dimensionless time of approximately 4.0, the determinant no longer changes. This implies that after this dimensionless time, the temperature is returning to its initial state (a dimensionless value of zero) and little additional information is being provided for the estimation of the thermal properties. Therefore, the experiments can be concluded after a $t_N^+$ of 4.0. Again, however, as was the case for Configuration 1, this is a conservative choice and a smaller value, such as 3.5, could have also been chosen.

5.2.1.2.5 Verification of the Optimal Temperature Sensor Location on the $x^+$ Axis

To verify the optimal location of the temperature sensor along the $x^+$ direction, for
Figure 5.28. Modified Dimensionless Determinant, $D^+$, Used to Determine the Dimensionless Optimal Experimental Time, $(t_N)^+$. 
which a value of zero was determined, the dimensionless determinant was calculated using the optimal values for $y_s^+, L_{p,2}^+$, and $t_h^+$ for various $x_s^+$ locations. The results are shown in Fig. 5.29 against dimensionless time. As seen from this figure, the maximum determinant occurred when the sensor was at the heated surface ($x_s^+=0.0$), confirming the optimal result obtained for the $x_s^+$ location.

5.2.1.2.6 Maximum Determinant Using the Optimal Experimental Parameters

In summary, the above optimization procedure resulted in the following optimal experimental parameters for Configuration 2: $x_s^+=0.0$, $y_s^+=0.77$, $L_{p,2}^+=0.89$ and $t_h^+=1.55$. Using these optimal parameters, the dimensionless determinant, $D^+$, was plotted as a function of dimensionless time, where a maximum of $4.29 \times 10^{-7}$ occurred, as shown in Fig. 5.30. Again, the reason why these determinant values are less than those obtained for the one-dimensional case is the same as discussed in Section 5.2.1.1.7.

5.2.1.2.7 Temperature Distributions for Configuration 2

Using the optimal values for $x_s^+$ and $L_{p,2}^+$, the temperature was plotted for various $y_s^+$ locations for four different dimensionless times; initial (0.1), two intermediate (0.5 and 1.55), and steady state (4.0) (Fig. 5.31). Note that these temperature distributions were calculated with the heat flux applied for the entire experimental time, $t_N^+$. The desired optimal values occur when the determinant is a maximum, or when the sensitivity coefficients are the most sensitive to temperature changes. As mentioned previously, in the case of thermal conductivity, this can occur when the temperature gradient is large.
Figure 5.29. Determination of the Optimal Sensor Location on the $x^*$ ($x/L_x$) Axis.
Figure 5.30. Dimensionless Determinant, $D^*$, Calculated Using the Optimal Experimental Parameters of $x_s^* = 0.0$, $y_s^* = 0.77$, $L_{p,2}^* = 0.89$, and $t_n^* = 1.55$. 
Figure 5.31 Temperature ($T$) Distribution for Various $y_*$ Locations Calculated Using Four Different Experimental Times.
As seen from this figure, at an optimal $y_s^+$ location of 0.77, the temperature gradient is steep, and therefore, it is expected that the sensitivity coefficients for $k_{y_{eff}}$ are large in magnitude. However, the optimal $y_s^+$ location for this design again does not occur at the steepest temperature gradient and results for the same reasons given in the Configuration 1 analysis.

The temperature was also calculated as a function of dimensionless time using the optimal experimental parameters determined previously (Fig. 5.32). As seen in Fig. 5.32, the temperature distribution behaves the same way as for Configuration 1, where the heat flux is terminated as the temperature approaches steady state ($t'_h=1.55$). This is again consistent with Fig. 5.31, where applying the heat flux for the dimensionless time of 1.55 results in temperatures close to the steady state temperatures attained at $t'^*=4.0$.

5.2.1.2.8 Sensitivity Coefficients Using the Optimal Experimental Parameters

Using the optimal experimental parameters determined, the dimensionless sensitivity coefficients for the three effective thermal properties, $k_{x_{eff}}$, $k_{y_{eff}}$, and $C_{eff}$, were calculated and plotted as a function of dimensionless time in Fig. 5.33. Here, it is seen that the sensitivity coefficients for $k_{x_{eff}}$ and $C_{eff}$ are relatively large in magnitude, while for $k_{y_{eff}}$, the coefficients are much smaller (of the order 0.1). It is also seen that after a dimensionless time of approximately four, all of the coefficients converge to zero, indicating that temperature measurements taken beyond this time supply little additional information for the estimation procedure. This result is consistent with both the temperature distribution in Fig. 5.32, where its initial state was attained after this
Dimensionless Temperature, $T$.

dimensionless time, and with the determined optimal experimental time, where after a $t_N^*$ of 4.0, the determinant no longer varied (Fig. 5.28).

Again, the sensitivity coefficients should be analyzed to see if they are correlated. If correlation occurs, the thermal properties cannot be estimated independently. From Fig. 3.33, linear independence is again evident between $C_{eff}$ whose coefficient changes from negative to positive values, and both $k_{x,eff}$ and $k_{y,eff}$ where the coefficients are always negative. However, as with Configuration 1, it was desired to determine if the sensitivity coefficients for $k_{x,eff}$ and $k_{y,eff}$ are correlated. If correlation occurs, then only the ratio, $\kappa_{xy}$, can be estimated. To test for possible correlation, the ratio of $X_{x,eff}/X_{y,eff}$ was again calculated, with the results shown in Fig. 5.34. If a straight line occurs, correlation exists. From this figure, however, it is evident that a linear line does not occur, and therefore, the coefficients are linearly independent and $k_{x,eff}$ and $k_{y,eff}$ can be estimated simultaneously.

5.2.1.3 Comparison of Configurations 1 and 2

After calculating the optimal experimental parameters for both Configurations 1 and 2, the configurations were compared to determine which one would provide the most accurate thermal property estimates. This comparison can be made by determining which configuration has the largest maximum determinant. Figure 5.35 shows the dimensionless determinants as a function of dimensionless experimental time calculated using the optimal experimental parameters found for each configuration. From this figure, it is
Figure 5.35. Comparison of the Dimensionless Determinant, $D^*$, for Configurations 1 and 2.
evident that the design with constant temperatures on the two sides (Configuration 1) will provide more accurate estimates than the design with insulated sides (Configuration 2). However, this conclusion requires further analysis by viewing the sensitivity coefficients for each configuration, as shown in Fig. 5.36. Here, it is seen that the sensitivity coefficients for \( k_{x_{\text{eff}}} \) and \( C_{\text{eff}} \) are 20% and 9% larger in magnitude, respectively, for Configuration 2 than Configuration 1. However, the sensitivity coefficient for \( k_{y_{\text{eff}}} \) is 136% larger in magnitude for Configuration 1 than Configuration 2. (Note, these percents were calculated using the largest point on each of the curves). This difference in \( k_{y_{\text{eff}}} \) is much more substantial than that for \( k_{x_{\text{eff}}} \) and \( C_{\text{eff}} \). From viewing these sensitivity coefficients, it can be concluded that when estimating all three thermal properties simultaneously, Configuration 1 should be utilized, since it will provide approximately the same amount of information for \( k_{x_{\text{eff}}} \) and \( C_{\text{eff}} \) that Configuration 2 would provide, but considerably more information for the estimation of \( k_{y_{\text{eff}}} \). This result seems reasonable since a greater temperature variation would occur in the \( y^+ \) direction (the same direction as \( k_{y_{\text{eff}}} \)) when the walls are maintained at a constant temperature of zero rather than insulated, where the wall temperatures are allowed to rise (only the gradient at the wall is required to remain equal to zero). This result is consistent with comparing the maximum determinant values between the two configurations, as discussed previously.

5.2.1.4 Other Optimized Parameters

For both configurations used in the two-dimensional analysis, the optimal parameters were determined using a \( L_{xy} \) of 0.048 and a \( \kappa_{xy} \) of 7. A \( L_{xy} \) ratio of this
Figure 5.36. Comparison of the Dimensionless Sensitivity Coefficients, $X_{k_1}^*$, $X_{k_2}^*$, and $X_{C_{a.g}}^*$, for Configurations 1 and 2.
magnitude is typical of the sizes of composite samples used in experimental designs. The samples used by Loh and Beck (1991) to determine the effective thermal conductivities parallel ($k_{y,\text{eff}}$) and perpendicular ($k_{x,\text{eff}}$) to the fibers, from which they determined a thermal conductivity ratio of 7, were also of this magnitude. Since this study uses similar carbon-epoxy composite materials, a $\kappa_{xy}$ of 7 was also used in this investigation. However, to demonstrate how this optimization analysis could be extended to other composite dimensions or effective thermal conductivity ratios, different values for $\kappa_{xy}$ and $L_x$ were also used in the optimization procedure. These combinations include $L_x$ equal to 0.048, 0.5, and 1.0, and $\kappa_{xy}$ equal to 7, 1, and 1/7. The results for all combinations are discussed in the following subsections.

5.2.1.4.1 Various $L_{xy}$ and $\kappa_{xy}$ Combinations Used for Configuration 1

The first combination investigated was $L_{xy} = 0.5$, and $\kappa_{xy} = 7$. This $L_{xy}$ results in the composite thickness in the direction of heat transfer (the $x^+$ direction in this analysis) being ten times greater than when $L_{xy}$ equalled 0.048. Using the same procedure discussed in Section 5.2.1.1, the general region of the maximum determinant was calculated. Using the optimal experimental parameters found for this region, the sensitivity coefficients were calculated and plotted, as shown in Fig. 5.37. From this figure, it is seen that the coefficients reach steady state very quickly. This occurs because of the significant increase in the thickness in the $x^+$ direction, creating more material to absorb the heat produced from the applied heat flux. Therefore, it can be concluded that using this $L_{xy}$ and $\kappa_{xy}$ combination provides inadequate information for the estimation
Figure 5.37. Sensitivity Coefficients for Configuration 1 Using a $L_{xy}$ ($L_x/L_y$) of 0.5 and $\kappa_{xy}$ ($k_{y-\sigma}/k_{x-\sigma}$) of 7.
procedure and is not recommended as an experimental design. Based on this result, it is evident that raising $L_{xy}$ to 1.0, where the thickness in the $x^+$ direction is additionally increased, will provide similar results, and therefore, should also not be used as an experimental design. When comparing these two results to the case previously analyzed in Section 5.2.1.1.9 ($L_{xy} = 0.048, \kappa_{xy} = 7$), it is seen that when using a thin sample for this thermal conductivity ratio, more information is available for the estimation of the thermal properties. This is shown by the larger sensitivity coefficients that result for all three parameters (Fig. 5.24).

Next, to determine the effects of different effective thermal conductivity ratios, $\kappa_{xy}$ was decreased to 1, and again, combinations for $L_{xy}$ equal to 0.048, 0.5, and 1.0 were analyzed. Note that a $\kappa_{xy}$ of 1 implies that the resistance to heat flow is equal in both the $x^+$ and $y^+$ directions (due to equal effective thermal conductivities).

For all three $L_{xy}$-$\kappa_{xy}$ combinations, the sensitivity coefficients were plotted using experimental parameters around the maximum determinant region. These results are shown in Figs. 5.38, 5.39, and 5.40 for $L_{xy}$ values of 0.048, 0.5, and 1.0, respectively. From Fig. 5.38, it is seen that when $L_{xy}$ equals 0.048, sufficient information is provided for the estimation of $k_{x\text{-eff}}$ and $C_{\text{eff}}$, where the sensitivity coefficients are large in magnitude. However, the coefficients for $k_{y\text{-eff}}$ are quite small, remaining practically zero for the entire experimental time. This implies that the estimation of $k_{y\text{-eff}}$ will be difficult, and most likely, inaccurate.

For $L_{xy}$ equal to 1.0 (Fig. 5.40), it is again seen that the sensitivity coefficients
Figure 5.38. Sensitivity Coefficients for Configuration 1 Using a $L_{xy} (L_x/L_y)$ of 0.048 and $\kappa_{xy}$ ($k_{y,\text{eff}}/k_{x,\text{eff}}$) of 1.
Figure 5.39. Sensitivity Coefficients for Configuration 1 Using a $L_{xy} (L_x/L_y)$ of 0.5 and $\kappa_{xy}$ ($k_{y,\text{eff}}/k_{x,\text{eff}}$) of 1.
Figure 5.40. Sensitivity Coefficients for Contraction 1 Using a 1,0 and k. Dimensionless Experimental Time (\(\kappa^{\prime}T\)).

Dimensionless Sensitivity Coefficients

- \(\frac{\partial}{\partial x} \phi \cdot x\)
- \(\frac{\partial}{\partial y} \phi \cdot x\)
- \(\frac{\partial}{\partial z} \phi \cdot x\)
reach steady state fairly rapidly, and therefore, little information is being supplied for the estimation of the thermal properties.

The sensitivity coefficients calculated using a $L_{xy}$ of 0.5 (Fig. 5.39), however, are all relatively large in magnitude. This implies that when using this $L_{xy}$ ratio, difficulty in the estimation of the thermal parameters will not be encountered.

In conclusion, when a composite has equal effective thermal conductivities parallel and perpendicular to the fibers, the optimal $L_{xy}$ ratio is not for either a real small or real large thickness in the direction of heat flow, but instead, falls somewhere in between. An $L_{xy}$ of 0.5 may perhaps be the optimal ratio; however, this conclusion would require further analysis.

The last combination of $L_{xy}$'s and $\kappa_{xy}$ for Configuration 1 were again, $L_{xy}$ equal to 0.048, 0.5, and 1.0, with $\kappa_{xy}$ equal to 1/7. Now, the effective thermal conductivity perpendicular to the fibers (in the direction of the heat flow) is 7 times larger than the thermal conductivity parallel to the fibers. The sensitivity coefficients for all three combinations, $L_{xy}$ equal to 0.048, 0.5, and 1.0, were calculated using the optimal experimental parameters determined around the maximum determinant region. These are shown in Figs. 5.41, 5.42, and 5.43, respectively. From Fig. 5.41, where $L_{xy} = 0.048$, it is seen that $k_{y\text{-eff}}$ cannot be estimated since the sensitivity coefficient is zero. This occurs because the larger thermal conductivity ($k_{x\text{-eff}}$) is parallel to the heat flow (in the $x^*$ direction). Since the sample is so thin in this direction, the majority of heat is conducted along this path, causing very small temperature variations to occur perpendicular to the heat flow, along the $y^*$ axis.
Figure 5.41. Sensitivity Coefficients for Configuration 1 Using a $L_{xy}$ ($L_x/L_y$) of 0.048 and $\kappa_{xy}$ ($k_{x \rightarrow y}/k_{x \rightarrow y}$) of $1/7$. 
Figure 5.42. Sensitivity Coefficients for Configuration 1 Using a $L_{xy}$ ($L_x/L_y$) of 0.5 and $\kappa_{xy}$ ($k_{y,ef}/k_{x,ef}$) of 1/7.
Figure 5.43: Sensitivity Coefficients for Configuration 1 Using a Iteration of 1.0 and x

Dimensionless Experimental Time, \( t^* \)

\[ \xi \left( \frac{\delta}{\delta^*} \right) \]

\[ \xi \left( \frac{\delta}{\delta^*} \right) \]

\[ \xi \left( \frac{\delta}{\delta^*} \right) \]

Dimensionless Sensitivity Coefficients
From Fig. 5.42, is seen that increasing $L_{xy}$ to 0.5 provides better results for the estimation of $k_{y\text{-eff}}$, where the sensitivity coefficient is larger in magnitude. This occurs because the thickness in the direction of heat flow, $x^+$, increases. Therefore, the conduction process is slowed, allowing more heat to be dissipated in the $y^+$ direction.

This result is even more significant when increasing $L_{xy}$ to 1.0 (Fig. 5.43), where the largest magnitude for the $k_{y\text{-eff}}$ sensitivity coefficient out of all three combinations occurs.

It can be concluded from these results that when the effective thermal conductivity in the direction of heat flow is much larger than the thermal conductivity in the direction perpendicular, a better experimental design would consist of a larger thickness in the $x^+$ direction, allowing more heat to be dissipated in the direction perpendicular to the heat flow.

5.2.1.4.2 Various $L_{xy}$ and $\kappa_{xy}$ Combinations Used for Configuration 2

Again, the first combination investigated was $L_{xy} = 0.5$ and $\kappa_{xy} = 7$. The sensitivity coefficients calculated using the optimal experimental parameters in the region of the maximum determinant are shown in Fig. 5.44. Here, it is seen that not much information is being supplied for the estimation of $k_{y\text{-eff}}$, where the sensitivity coefficient is small. This occurs because of the increased thickness in the $x^+$ direction. Raising $L_{xy}$ to 1.0 will further increase this thickness, and therefore, similar results are expected. Therefore, it can be concluded that when the thermal conductivity in the direction of heat flow is much smaller than the thermal conductivity perpendicular to the direction of heat flow, a
Figure 5.44. Sensitivity Coefficients for Configuration 2 Using a $L_{xy}$ ($L_y/L_x$) of 0.5 and $\kappa_{xy}$ ($k_{y\text{-eff}}/k_{x\text{-eff}}$) of 7.
composite sample with a small thickness should be used for the best results. This result is consistent with the case previously analyzed \((L_{xy} = 0.048, \kappa_{xy} = 7)\), where the sensitivity coefficients for all three parameters are slightly larger than when \(L_{xy} = 0.5\).

Next, \(\kappa_{xy}\) was decreased to 1 and similar combinations for \(L_{xy}\) were analyzed. Again, note that this \(\kappa_{xy}\) implies that the resistance to heat flow is equal in both the \(x^+\) and \(y^+\) directions. The sensitivity coefficients calculated using the experimental parameters around the maximum determinant region for all three \(L_{xy}-\kappa_{xy}\) combinations are shown in Figs. 5.45, 5.46, and 5.47. In Fig. 5.45 \((L_{xy} = 0.048)\), it is seen that having a small thickness in the \(x^+\) direction creates difficulty in the estimation of \(k_{y-eff}\), where the sensitivity coefficient is essentially zero for the entire experimental time. This result is consistent with that obtained for Configuration 1 at a similar \(L_{xy}\) ratio. However, when \(L_{xy}\) is increased to 0.5 or 1.0 (Figs. 5.46 and 5.47, respectively), the \(k_{y-eff}\) sensitivity coefficients are of approximately the same magnitude, only different in sign. However, this magnitude is still small and therefore, neither an \(L_{xy}\) of 0.5 or 1.0 is the optimal value. The optimal \(L_{xy}\) may lie between these values, but the exact determination would require further analysis.

The last combinations of \(L_{xy}\)'s and \(\kappa_{xy}\) for Configuration 2 were again, \(L_{xy}\) equal to 0.048, 0.5, and 1.0, with \(\kappa_{xy}\) equal to 1/7. Now, the effective thermal conductivity perpendicular to the fibers (in the direction of heat flow), \(k_{x-eff}\), is 7 times larger than the thermal conductivity parallel to the fibers, \(k_{y-eff}\). The sensitivity coefficients for all three combinations, \(L_{xy}\) equal to 0.048, 0.5, and 1.0, were calculated using the optimal
Figure 5.45. Sensitivity Coefficients for Configuration 2 Using a $L_{xy} (L_x/L_y)$ of 0.048 and $\kappa_{xy}$ ($k_{y,\text{eff}}/k_{x,\text{eff}}$) of 1.
Figure 5.46. Sensitivity Coefficients for Configuration 2 Using a \( L_{xy} \) \( (L_x/L_y) \) of 0.5 and \( \kappa_{xy} \) \( (k_{y-ef}/k_{x-ef}) \) of 1.
Figure 5.47. Sensitivity Coefficients for Configuration 2 Using a $L_{xy}$ ($L_x/L_y$) of 1.0 and $\kappa_{xy}$ ($k_{y\text{-eff}}/k_{x\text{-eff}}$) of 1.
experimental parameters determined around the maximum determinant region. These results are shown in Figs. 5.48, 5.49, and 5.50, respectively. From each of these figures, the same results are seen as for Configuration 1, where the best experimental design consisted of a larger thickness in the $x^+$ direction (a $L_{xy}$ of 1.0), allowing more heat to be dissipated in the direction perpendicular to the applied heat flux. This is evident by the larger sensitivity coefficient for $k_{y-ext}$ when $L_{xy} = 1.0$ (Fig. 5.50) than when $L_{xy}$ equals either 0.5 (Fig. 5.49), where the magnitude of the coefficient is 0.1, or 0.048 (Fig. 5.48), where the coefficients are essentially zero. Recall that this zero coefficient results for $L_{xy} = 0.048$ because the sample is very thin in the direction of heat transfer, $x^+$ (and the direction of the larger effective thermal conductivity). Therefore, the majority of the heat is conducted along the $x^+$ axis, causing very small temperature variations to occur along the $y^+$ axis, and as a result, the estimation of $k_{y-eff}$ becomes difficult.
Figure 5.48. Sensitivity Coefficients for Configuration 2 Using a $L_{xy} (L_x/L_y)$ of 0.048 and $\kappa_{xy}$ ($k_{y,\text{eff}}/k_{x,\text{eff}}$) of 1/7.
Figure 5.49. Sensitivity Coefficients for Configuration 2 Using a \( L_{xy} \ (L_x/L_y) \) of 0.5 and \( \kappa_{xy} \ (k_{y\text{-eff}}/k_{x\text{-eff}}) \) of 1/7.
Figure 5.50. Sensitivity Coefficients for Configuration 2 Using a $L_{xy} (L_x/L_y)$ of 1.0 and $\kappa_{xy}$ ($k_{y,eff}/k_{x,eff}$) of 1/7.
Chapter 6

Conclusions and Summary

The primary objectives of this study were to develop optimal experimental designs to be used for the estimation of thermal properties of composite materials. This includes both one-dimensional (isotropic) and two-dimensional (anisotropic) analyses. Experiments were then conducted for the one-dimensional case, using the optimal design, to estimate the effective thermal conductivity perpendicular to the fibers and the effective volumetric heat capacity of a composite consisting of IM7 graphite fibers and a Bismaleimide epoxy matrix. The estimation procedure used was the modified Box-Kanemasu method. The following conclusions can be made based on the obtained results.

6.1 Optimal Experimental Designs

In this investigation, optimal experimental designs were determined for both one-dimensional and two-dimensional heat conduction processes. In the two-dimensional analysis, two different configurations were investigated, both allowing for the estimation...
of the effective thermal conductivity in two directions and the effective volumetric heat capacity.

6.1.1 One-Dimensional Optimal Experimental Design

For the one-dimensional experimental design, three experimental parameters were optimized: dimensionless heating time, temperature sensor location, and dimensionless experimental time. The following conclusions can be made based on the results obtained for the specific geometry and boundary conditions used in this analysis:

1) The optimal dimensionless heating time is 2.2. However, the maximum determinant curve had a rather flat peak between heating times of 2.0 and 2.5. Therefore, any values within this range can be used.

2) The optimal temperature sensor location is at the heated surface.

3) The optimal dimensionless experimental time is approximately 5.0. Note however, that this is a conservative choice.

6.1.2 Two-Dimensional Optimal Experimental Designs

For the two-dimensional experimental design, two configurations were analyzed. Both configurations had a heat flux applied over a portion of one boundary, with the remainder of the boundary insulated. In addition, Configuration 1 had known, constant temperatures at the remaining three boundaries, while the second configuration had a known constant temperature at the boundary opposite to the heat flux and insulated conditions at the remaining two boundaries. For each configuration, the optimal
experimental parameters determined include the temperature sensor location \((x_s^+, y_s^+\)), the
dimensionless heating time, the location of the heat flux, and the dimensionless experimental time. Based on the obtained results for the specific geometry and boundary conditions used in this analysis, the following conclusions can be made:

6.1.2.1 Conclusions for Configuration 1

1) The optimal dimensionless heating time is 1.4.
2) The optimal temperature sensor location occurs at a \(x_s^+\) of 0.0 (or at the heated surface) and a \(y_s^+\) of 0.13 (13% of \(L_y\) from the bottom edge).
3) The optimal location of the heat flux is across the entire \(y^+\) boundary \((L_{p,1}^+ = 1.0)\).
4) The optimal dimensionless experimental time is approximately 4.0. Note however, that this is a conservative choice.

6.1.2.2 Conclusions for Configuration 2

1) The optimal dimensionless heating time is 1.55.
2) The optimal temperature sensor location occurs at a \(x_s^+\) of 0.0 (or at the heated surface) and a \(y_s^+\) of 0.77 (77% of \(L_y\) from the bottom edge).
3) The optimal location of the heat flux is across 89% of the \(y^+\) boundary \((L_{p,2}^+ = 0.89)\).
4) The optimal dimensionless experimental time is approximately 4.0. Again, this is a conservative value.

The following conclusion can also be made when comparing the two configurations:
1) Configuration 1 should be utilized when estimating $k_{x_{-\text{eff}}}$, $k_{y_{-\text{eff}}}$, and $C_{\text{eff}}$ simultaneously, increasing the accuracy of the resulting property estimates.

6.2 Thermal Property Estimates

The estimation of the thermal properties, namely the effective thermal conductivity perpendicular to the fibers and the effective volumetric heat capacity, was conducted for the one-dimensional analysis using the modified Box-Kanemasu method. This estimation procedure requires both measured and calculated temperatures. The measured temperatures were obtained from experiments conducted using the optimal experimental parameters. The following conclusions can be made based on the results of this portion of the investigation:

1) The effective thermal conductivity perpendicular to fibers ($k_{x_{-\text{eff}}}$) is 0.52 W/m°C.

2) The effective volumetric heat capacity ($C_{\text{eff}}$) is 1.48 MJ/m$^3$°C.

3) The estimated parameters are both reliable, as shown by the small confidence intervals and the Root Mean Square values.

4) The estimates for $k_{x_{-\text{eff}}}$ are more accurate than for $C_{\text{eff}}$.

5) The sequential estimates converge to a steady value, indicating that the heat conduction model and experimental design are satisfactory.

6) No bias error in the calculated temperatures is apparent.
Chapter 7

Recommendations

The estimation procedure used in this investigation to determine the effective thermal conductivity perpendicular to the fiber axis and the effective volumetric heat capacity proved to be quite accurate. However, because the problem had been simplified by conducting the required experiments at room temperature, the actual environmental conditions that many composites, especially in aerospace vehicles, are subjected to have not been accurately described. These operating conditions usually occur over extreme temperature ranges, resulting in temperature dependent thermal properties. Therefore, in order to accurately determine the temperature distributions within these structures during actual operational conditions, it is necessary to characterize this temperature dependence. The estimation procedure can be modified to include this dependence by assuming a functional relationship between the thermal properties and temperature. For example, the thermal conductivity can be approximated by a piece-wise linear function with temperature:

\[
k_{\text{eff}} = k_i + (k_{i+1} - k_i) \left( \frac{T - T_i}{T_{i+1} - T_i} \right)
\]

(7.1)
where \( k_i \) and \( k_{i+1} \) are the coefficients to be estimated. The mathematical model can now be modified to include temperature dependent properties and the least squares function given in Eq. (3.33) can be minimized with respect to \( k_i \) and \( k_{i+1} \).

In addition, it is also recommended that the results of the two-dimensional optimization procedure be verified. This can be done by conducting experiments for the two configurations using both the optimal experimental parameters and arbitrary experimental parameters. The measured temperatures will then be utilized in the estimation procedure to determine the thermal properties, \( k_x \text{eff} \), \( k_y \text{eff} \), and \( C_{\text{eff}} \). The estimates obtained using the experiments conducted with the optimal parameters should provide the smallest confidence intervals. (Recall that the optimization procedure selected for this study has the effect of minimizing the confidence intervals of the estimated parameters).

The Box-Kanemasu method could also be implemented to determine the thermal properties using both configurations simultaneously. Based on the magnitude of the sensitivity coefficients, temperature measurements from Configuration 2 would be used to estimate \( k_x \text{eff} \) and \( C_{\text{eff}} \), while \( k_y \text{eff} \) would be estimated using measurements taken from Configuration 1. Using both configurations together will then supply the most accurate estimates for all three thermal properties.

Other properties could also be estimated, such as the thermal contact resistance between composite components. Here, the least squares function would be minimized with respect to the contact resistance. Furthermore, efforts could be taken for the analysis of complex structures.

The FORTRAN program MODBOX.FOR

This program, MODBOX.FOR, uses the modified Box-Kanemasu method to estimate the thermal properties.

PROGRAM NLINA

CCCCCCCCC PROGRAM DESCRIPTION CCCCCCCCC
C
C THIS PROGRAM USES THE MATRIX INVERSION LEMMA (BASED ON
C THE GAUSS LINEARIZATION METHOD) AND THE BOX-KANEMASU
C METHOD TO ESTIMATE THE PARAMETERS OF A GIVEN MODEL.  C

Input file for MODBOX.FOR

This file represents a sample input file to be used in MODBOX.FOR for the estimation of the thermal properties. The first row of numbers represents the number of data points, the number of parameters to be estimated, the number of independent variables, the maximum number of iterations to be performed, the model number, and the usual printouts, respectively. The second row represents the initial guesses for $k_{x\text{-eff}}$ and $C_{a\text{-eff}}$ which are to be estimated. The first column is the index, the second column is the values of the temperatures, the third is the standard deviation of the measurement errors, and the fourth column is the independent variable, time. At the end of the columns, the first row represents the number of extra parameters to be used in the program. These parameters are then given in the next row, and represent the magnitude of the heat flux, the initial temperature (and in this analysis, the constant temperature at the boundary), the heating time, and the composite thickness, $L_{z\text{-eff}}$, respectively.

Finite Element (EAL) program

This is the finite element program (EAL) used to estimate the thermal properties.

EAL THERMAL ANALYSIS RESEARCH PROJECT, EXP. 3

Debbie A. Moncman

This problem solves for the temperature distribution in a 2-D plate with dimensions LXm x LYm. It then uses the Modified Box-Kanemasu method to sequentially estimate the thermal properties of the material. The properties of interest are the effective thermal conductivity and the volumetric heat capacity. The left and right surfaces of the flat plate are insulated, the bottom surface is maintained at a constant temp, and at the top surface is a constant heat flux. The assumptions used are: Transient, one-dimensional conduction, constant properties, and no internal heat generation.

APPENDIX G

Uncertainty Due to Experimental Measurements

The uncertainty in the estimated thermal properties due to experimental measurement errors can be found from

$$\delta R = \sqrt{\sum_{i=1}^{N} \left( \frac{\partial R}{\partial X_i} \delta X_i \right)^2}$$  \hspace{1cm} (G.1)

where $\delta R$ is the uncertainty in the thermal property being analyzed, $\delta X_i$ is the uncertainty in the experimental variable, and the partial derivative of $R$ with respect to $X_i$ is the sensitivity coefficient with respect to the measurement, $X_i$. In the experiments conducted in this investigation, error could be associated with the temperature ($X_T$), voltage ($X_V$), or current ($X_I$) measurements. Therefore, the uncertainty in the effective thermal conductivity perpendicular to the fibers ($k_{x\text{-eff}}$) would be given by

$$\delta k_{x\text{-eff}} = \left[ \left( \frac{\partial k_{x\text{-eff}}}{\partial T} \delta X_T \right)^2 + \left( \frac{\partial k_{x\text{-eff}}}{\partial V} \delta X_V \right)^2 + \left( \frac{\partial k_{x\text{-eff}}}{\partial I} \delta X_I \right)^2 \right]^{1/2}$$  \hspace{1cm} (G.2)

Using this equation, a $\delta k_{x\text{-eff}}$ of ±0.035 W/m°C was calculated. In Chapter 5, the mean value for $k_{x\text{-eff}}$ was estimated as 0.518 ± 0.028 W/m°C. This uncertainty of ±0.028 W/m°C, associated with the 95% confidence region, is approximately 20% smaller than $\delta k_{x\text{-eff}}$ found from the measurement errors. This result implies that the actual error associated with $k_{x\text{-eff}}$ may be larger than estimated.
