A GENUINELY MULTIDIMENSIONAL UPWIND SCHEME
AND AN EFFICIENT MULTIGRID
FOR THE COMPRESSIBLE EULER EQUATIONS*

DAVID SIDILKOVER
ICASE, MAIL STOP 132C

HAMPTON, VA 23681

Abstract. We present a new approach towards the construction of a genuinely multidimensional high-resolution scheme for computing steady-state solutions of the Euler equations of gas dynamics. The unique advantage of this approach is that the Gauss-Seidel relaxation is stable when applied directly to the high-resolution discrete equations, thus allowing to obtain a very good efficiency of the multigrid steady-state solver. This is the only high-resolution scheme known to us that has this property. The two-dimensional scheme is presented in details. It is formulated on triangular (structured and unstructured) meshes and can be interpreted as a genuinely two-dimensional extension of the Roe scheme. The quality of the solutions obtained using this scheme and the performance of the multigrid algorithm are illustrated by the numerical experiments. Construction of the three-dimensional scheme is outlined briefly as well.

1. Introduction. A need for a fast and accurate steady-state compressible flow solver exists in many areas of science and engineering. Perhaps, such a need is particularly acute for the problem of aerodynamic design. In this case the steady-state solutions of the compressible flow past bodies have to be computed repeatedly, each time with variations in the body’s geometry. This allows to find the shape with optimal in a certain sense aerodynamic parameters relying on computations only. Thus the necessity of the costly wind-tunnel experiments can be largely reduced.

The search for the genuinely multidimensional schemes for the compressible Euler equations was motivated by the expectation, that they will provide new possibilities (comparing to the dimensionally split schemes, which are of the common use now), like:

- capturing physics of the fluid flow more accurately;
- constructing a more efficient steady-state (multigrid) solver.

Considerations regarding the first point can be found in [14],[15]. The main motivation for constructing the truly multidimensional scheme in this work is the improvement of multigrid efficiency. It was observed in [20] that pointwise Gauss-Seidel relaxation is unstable when applied directly to the high-resolution dimensionally split scheme even in the simple case of two-dimensional scalar advection equation. Therefore, the steady-state Euler solver constructed in [21] relies on the defect correction technique, which is not a fully efficient way to utilize multigrid methods. Another possibility to avoid this difficulty is to use a multigrid algorithm that employs a well-known multistage Runge-Kutta relaxation technique which was developed in [9],[7],[8].

However, any further improvement of the multigrid efficiency requires to address this problem directly: it is necessary to develop a new high-resolution (at least at the steady-state) discrete scheme, such that Gauss-Seidel relaxation is stable when applied directly to the resulting discrete equations. This was the main motivation for constructing the genuinely two-dimensional advection scheme in the control volume context in [17],[18]. The novel feature of this scheme was the two-dimensional limiter, i.e. the limiter function that relies on the ratio of two finite differences in different directions.

There has also been developed another class of genuinely two-dimensional advection schemes – the so-called “fluctuation-splitting” schemes. (see [6],[22]). These schemes are also equipped with a nonlinear mechanism that allows to combine high-resolution and positivity property. Several variants of such a nonlinear mechanism were devised using some geometric considerations. The remarkable feature of this approach is the simplicity of the schemes formulated on unstructured triangular grids.

The strong relationship between the fluctuation-splitting and control volume advection schemes was established in [19]. As a result, the fluctuation-splitting scheme that utilizes the two-dimensional limiters was constructed. The action of the limiter function can be given a purely algebraic interpretation.

Even though some genuinely two-dimensional advection schemes where available already several years ago, the task of extending these ideas to the systems of equations appeared to be rather difficult.

The “algebraization” of the advection scheme formulation appeared to be crucial for the purpose of this work - constructing a truly multidimensional scheme for the Euler system. The resulting scheme is capable of producing high-resolution steady-state solutions. Its unique feature is that the Gauss-Seidel relaxation is stable when applied directly to the high resolution discrete equations.
The paper is organized as follows: in §2 we give a brief introduction into the fluctuation-splitting approach for the scalar advection equations and present consider-
ations for extending of this approach to the systems of equations in two dimensions. In
§3 we take a closer look on the Roe scheme for the Euler equations in one dimension.
Then we construct a truly two-dimensional scheme for the Euler systems on structured
(in §4) and unstructured (§5) triangular grids. In §6 we outline first as a preliminary
the construction of the three-dimensional advection scheme. Then we present a truly
three-dimensional scheme for the Euler system. §7 describes the multigrid algorithm
that employs the constructed truly two-dimensional scheme. Numerical experiments
are presented in §8, followed by discussion and conclusions in §9.

2. Preliminaries and motivation. In the first part of this section we illustrate
the fluctuation-splitting approach, first on the example of the scalar advection in one
dimension. Then we present the construction of a simple truly two-dimensional advection
scheme that relies on two-dimensional limiters. In the second part we discuss the
difficulties that arise when trying to apply the scalar advection schemes to discretize
the systems of equations in multidimensions.

2.1. Fluctuation-splitting approach. We shall give here a brief description
of the fluctuation-splitting advection scheme in one and two dimensions (for details
see [6],[19]). These schemes are required to have properties of positivity and linearity
preserving. We shall define here the positivity property.

Definition 2.1. A scheme is said to be of the positivity type if any solution value
on the new time level obtained by this scheme can be written as a positive combination
of the values from the previous time level.

Solutions obtained by the means of positive schemes will satisfy a certain maximum
principle and, therefore, do not exhibit oscillatory behavior in presence of dis-
continuities.

The notion of linearity preserving is used to characterize high-resolution at the
steady-state schemes. It is trivial in one dimension. Therefore, we shall give its precise
definition in §2.1.2.

2.1.1. Advection in one dimension. Consider a linear one-dimensional ad-
vection equation

\[ u_t + au_x = 0 \]  

We are interested in solving it numerically on a grid with meshsize \( h \) (see Fig.1).
Fluctuation is defined as the residual of the equation on the linear element multiplied
by the volume of the element. In our case the fluctuation on the segment \([i - 1, i]\) is
defined as the residual of (1) on this segment multiplied by its length \( h \)

\[ R = -a(u_i - u_{i-1}) \]

The numerical solution can be interpreted as a two-stage process

- compute the fluctuation on each element and distribute (split) it among the
  vertices of this element;
- update the solution at each vertex due to the accumulated portions of fluctua-
tions.
In our case if the fluctuation on the segment \([i-1,i]\) is distributed equally between the adjacent gridpoints

\[
\begin{align*}
    h u_{i-1}^{n+1} &= h u_{i-1}^n + \frac{\tau}{2} R + C.O.E. \\
    h u_i^{n+1} &= h u_i^n + \frac{\tau}{2} R + C.O.E.
\end{align*}
\]

we obtain the central scheme, which is neither positive nor stable, though second order accurate in space. Here “C.O.E.” stands for “contributions from other elements” and will be omitted in the remainder of this paper.

The upwind scheme can be obtained by adding a proper amount of the artificial viscosity to the central scheme. The fluctuation distribution formulae thus become

\[
\begin{align*}
    h u_{i-1}^{n+1} &= h u_{i-1}^n + \frac{\tau}{2} (R - \bar{R}) \\
    h u_i^{n+1} &= h u_i^n + \frac{\tau}{2} (R + \bar{R}),
\end{align*}
\]

where

\[\bar{R} = -|a|(u_i - u_{i-1}) = \text{sign}(a) R\]

is the artificial viscosity.

It is easy to see that in this case the entire fluctuation on the segment \([i-1,i]\) contributes either to the solution update either at the left or at the right nodes of the segment depending on the advection speed direction (sign).

2.1.2. Two-dimensional advection. Consider a linear two-dimensional advection equation

\[u_t + a u_x + b u_y = 0\]

The fluctuation on the triangle \(T\) (see Fig.2) is given by

\[
R = R^x + R^y,
\]

where

\[
\begin{align*}
    R^x &= -\frac{h}{2}[a(u_0 - u_3)] \\
    R^y &= -\frac{h}{2}[b(u_3 - u_4)]
\end{align*}
\]

Assuming that the fluctuation distribution formulae in this case are

\[
\begin{align*}
    h^2 u_0^{n+1} &= h^2 u_0^n + \frac{\tau}{2} (R^x + \bar{R}^x) \\
    h^2 u_3^{n+1} &= h^2 u_3^n + \frac{\tau}{2} [(R^x - R^x) + (R^y + \bar{R}^y)] \\
    h^2 u_4^{n+1} &= h^2 u_4^n + \frac{\tau}{2} (R^y - \bar{R}^y)
\end{align*}
\]

where \(R^x, R^y\) are the artificial viscosity terms defined by

\[
\begin{align*}
    \bar{R}^x &= \text{sign}(a) R^x \\
    \bar{R}^y &= \text{sign}(b) R^y
\end{align*}
\]

we obtain the dimensional upwind scheme which is positive, but only first order accurate.
**Definition 2.2.** The fluctuation-splitting scheme is called linearity preserving if whenever the fluctuation on the triangle $T$ vanishes then the scheme leads to a zero update in each of the three vertices of the triangle.

It was observed in [6] that the linearity-preserving schemes on structured grids produce numerical solutions that are second-order accurate in the steady state.

Introduce the following quantities

\[ R^x = R^x + R^y \Psi(Q) \]
\[ R^y = R^y + R^x \frac{\Psi(Q)}{Q} \]

where

\[ Q = -\frac{R^x}{R^y} \]

and $\Psi$ is a Lipschitz continuous limiter function such that

\[ 0 \leq \Psi(Q) \leq 1, \quad 0 \leq \frac{\Psi(Q)}{Q} \leq 1 \]

and

\[ \Psi(1) = 1 \]

Substituting $R^x$, $R^y$ for $R^x$, $R^y$ into (4) and (5) we obtain a linearity preserving (second order accurate at the steady-state in the case of structured grid) scheme. Using the following identity

\[ R^y \Psi(Q) \equiv -R^x \frac{\Psi(Q)}{Q} \]

it is easy to see that the scheme defined by (4), (5) and (6) is of the positive type.

It is also obvious from (10) that such scheme is conservative because

\[ R^x + R^y \equiv R^x + R^y \equiv R \]

(for more details see [19]).

**2.2. Hyperbolic systems of equations.** We shall explain here what is the main obstacle encountered when constructing a truly two-dimensional numerical scheme for a hyperbolic system of equations. We shall also describe what is our approach to overcome it. The understanding of the basic differences between one- and two-dimensional cases is required for this purpose. These differences will be illustrated on the linear systems of equations.

**2.2.1. One dimension.** Consider a system of conservation laws in one dimension

\[ u_t + f(u)_x = 0 \]

For the purpose of the discussion here it is sufficient to look at the linear constant coefficient case of (11). Consider a the following system of partial differential equations

\[ u_t + Au_x = 0 \]
where $A$ is $N \times N$ matrix. The system (12) is said to be hyperbolic if matrix $A$ has a complete set of real eigenvalues.

Denote $T$ - the matrix of right eigenvectors of $A$. Then

$$\Lambda = T^{-1}AT$$

is a diagonal matrix. Introducing characteristic variables

$$w = T^{-1}u$$

(12) can be rewritten as a set of $N$ decoupled advection equations:

(13)

$$w_t + \Lambda w_x = 0$$

- a set of $N$ decoupled advection equations. It is clear from (13) that a one-dimensional advection scheme can be applied in a straightforward way to solve a (linear) hyperbolic system of equations in one dimension. A discussion concerning the nonlinear Euler system in one dimension will be presented in the §3.

2.2.2. Two dimensions. A linear system of partial differential equations in two dimensions of the following form

(14)

$$u_t + Au_x + Bu_y = 0$$

is said to be hyperbolic if the matrix

$$\mathcal{A} = \cos \phi A + \sin \phi B$$

has a complete set of real eigenvalues for $\forall \phi : 0 \leq \phi \leq 2\pi$. In this case there exist matrices $T_A$ and $T_B$ such that $T_A^{-1}AT_A$ and $T_B^{-1}BT_B$ are diagonal. This is usually utilized to construct the so-called dimensionally split schemes. However, matrices $A$ and $B$ in general do not commute. Therefore, $T_A \neq T_B$, i.e. a hyperbolic system in two dimensions cannot be represented as a set of decoupled advection equations (unlike in one-dimensional case). This means that a truly two-dimensional advection scheme cannot be applied in a straightforward way to discretize a hyperbolic systems of equations.

Much of the research effort in the last several years concentrated on finding a way to apply the multidimensional advection schemes to discretize the hyperbolic systems of equations, in particular to the Euler equations of gas dynamics. One of the major directions was the so-called wave modeling (see [14],[5]). This approach concentrated on finding a way to represent (locally) the physics of two-dimensional flow of a compressible fluid by a finite number of simple waves, each one having an associated advection equation.

The approach we present here is concerned not with applying an advection scheme to discretize a system of equations in two dimensions, but rather with applying to the systems of equations the same strategy that was used when constructing a scalar advection scheme. The construction of the genuinely two-dimensional scheme for the Euler will be presented in §4 for the structured grids and in §5 for the general unstructured grids case.
3. Euler equations in one dimension and Roe scheme. Euler equations of gas dynamics in one dimension can be written as follows

\[ \mathbf{u}_t + \mathbf{F}(\mathbf{u})_x = 0, \]

where

\[ \mathbf{u} = \begin{pmatrix} \rho \\ \rho u \\ e \end{pmatrix}; \quad \mathbf{F}(\mathbf{u}) = \begin{pmatrix} \rho u \\ \rho u^2 + p \\ \rho u H \end{pmatrix}, \]

the enthalpy \( H \) is defined by

\[ H = \frac{e + p}{\rho} = \frac{e^2}{\gamma - 1} + \frac{1}{2} u^2, \]

the speed of sound

\[ c = \sqrt{\frac{\gamma p}{\rho}} \]

and the pressure

\[ p = (\gamma - 1)(e - \frac{1}{2} \rho u^2) \]

The Jacobian matrix

\[ \mathcal{A} = \frac{\partial \mathbf{F}}{\partial \mathbf{u}} \]

has real eigenvalues only.

In order to apply the upwind differencing approach to the nonlinear system (15) a particular conservative linearization procedure was introduced by Roe [13]. For two states \( \mathbf{u}_l \) and \( \mathbf{u}_r \), a matrix \( \mathcal{A}(\mathbf{u}_l, \mathbf{u}_r) \) was constructed having certain properties called together Property U. We address the reader to [13] for the details. Let us only mention here one of these properties: the following identity holds for any \( \mathbf{u}_l, \mathbf{u}_r \): \n
\[ \mathcal{A}(\mathbf{u}_l, \mathbf{u}_r) \cdot (\mathbf{u}_r - \mathbf{u}_l) \equiv \mathbf{F}(\mathbf{u}_r) - \mathbf{F}(\mathbf{u}_l). \]

3.1. Fluctuation-splitting formulation. Define the fluctuation on the considered element (segment \([i - 1, i]\), see Fig.1)

\[ R = -[\mathbf{F}(\mathbf{u}_i) - \mathbf{F}(\mathbf{u}_{i-1})]. \]

Following the Roe-linearization procedure we assume that the quantities which vary linearly on the segment \([i - 1, i]\) are the elements of the so-called parameter vector (see [13])

\[ \mathbf{m} = (m_1, m_2, m_3, m_4)^T = \sqrt{\rho}(1, u, v, H)^T. \]

Therefore, its average value on \([i - 1, i]\) is

\[ \bar{m} = \frac{m_{i-1} + m_i}{2} \]
Thus the following Roe-averaged quantities can be defined

\[
\begin{align*}
\rho^* &= \bar{m}_1^2 \\
\bar{u} &= \bar{m}_2 / \bar{m}_1 \\
\bar{H} &= \bar{m}_3 / \bar{m}_1
\end{align*}
\]

and

\[
\tilde{c}^2 = (\gamma - 1)(\bar{H} - \bar{u}^2/2)
\]

Introducing the Roe-averaged Jacobian \( \tilde{A} \equiv \bar{A}(u_{i-1}, u_i) \) and recalling (21) we can rewrite the fluctuation (22) in the following form

\[
R = -\tilde{A} \cdot (u_i - u_{i-1}).
\]

Having in mind the construction of an upwind scheme, it is convenient to use the following representation of the matrix \( \tilde{A} \) (see [13])

\[
\tilde{A} = \tilde{T} \tilde{\Lambda} \tilde{T}^{-1},
\]

where \( \tilde{\Lambda} \) is a diagonal matrix

\[
\tilde{\Lambda} = \begin{pmatrix} 
\lambda_1 & 0 & 0 \\
0 & \lambda_2 & 0 \\
0 & 0 & \lambda_3 
\end{pmatrix},
\]

where

\[
\lambda_1 = \bar{u}, \quad \lambda_{2,3} = \bar{u} \pm \tilde{c}
\]

are the eigenvalues and \( \tilde{T} = (\tilde{E}^1, \tilde{E}^2, \tilde{E}^3) \) is the matrix of right eigenvectors of \( \tilde{A} \)

\[
\tilde{E}^1 = \begin{pmatrix} 
1 \\
\bar{u} \\
\bar{u}^2/2 
\end{pmatrix}; \quad \tilde{E}^2 = \begin{pmatrix} 
1 \\
\bar{u} - \tilde{c} \\
\bar{H} - \bar{u}\tilde{c} 
\end{pmatrix}; \quad \tilde{E}^3 = \begin{pmatrix} 
1 \\
\bar{u} + \tilde{c} \\
\bar{H} + \bar{u}\tilde{c} 
\end{pmatrix}.
\]

The fluctuation-splitting formulation of the Roe scheme can be written as follows

\[
\begin{align*}
hu_{i-1}^{n+1} &= hu_{i-1}^n + \frac{\tilde{T}}{2}(R + \tilde{R}) \\
hu_i^{n+1} &= hu_i^n + \frac{\tilde{T}}{2}(R - \tilde{R}),
\end{align*}
\]

where

\[
\tilde{R} = -\tilde{T}\tilde{\Lambda}(w_i - w_{i-1})
\]

is the artificial viscosity, and

\[
w = \tilde{T}^{-1}u
\]

are the so-called characteristic variables.

Alternatively, the artificial viscosity can be also written as

\[
R = -|\tilde{A}|(u_i - u_{i-1})
\]

or

\[
R = -\text{sign}(\tilde{A})R
\]

7
3.2. Roe scheme revisited. It is convenient for the purpose of this work to introduce the following auxiliary variables $(s, u, p)^T$, where

$$ds = dp - \frac{dp}{c^2}$$

is the entropy. The non-conservative formulation of the Euler equations in these variables takes the following form

$$s_t + u s_x = 0$$
$$\rho u_t + \rho u u_x + p_x = 0$$
$$p_t + u p_x + \rho c^2 u_x = 0$$

Introduce the fluctuations of the Euler equations in the auxiliary variables

$$r = -\tilde{A} \cdot \begin{pmatrix} s_i - s_{i-1} \\ \rho^*(u_i - u_{i-1}) \\ p_i - p_{i-1} \end{pmatrix},$$

where

$$\tilde{A} = \begin{pmatrix} \tilde{u} & 0 & 0 \\ 0 & \tilde{u} & 1 \\ 0 & \tilde{c}^2 & \tilde{u} \end{pmatrix}$$

It can be easily verified that

$$R = C_a r,$$

where

$$C_a = \begin{pmatrix} 1 & 0 & 1/\tilde{c}^2 \\ \tilde{u} & 1 & \tilde{u}/\tilde{c}^2 \\ \tilde{u}^2/2 & \tilde{u}/\tilde{c}^2 & 1/(\gamma - 1) + u^2/(2\tilde{c}^2) \end{pmatrix}$$

Therefore, the Roe scheme (31) can be written as follows

$$hu_i^{n+1} = hu_i^n + \tilde{F}_l C_a (r + \tilde{r})$$

where the artificial viscosity

$$\tilde{r} = C_a^{-1} \tilde{R} = -C_a^{-1} \tilde{F} [\tilde{\Lambda} [w_i - w_{i-1}]]$$

with

$$C_a^{-1} = \begin{pmatrix} 1 - (\gamma - 1)\tilde{u}/(2\tilde{c}^2) & (\gamma - 1)\tilde{u}/\tilde{c}^2 & -(\gamma - 1)/\tilde{c}^2 \\ -\tilde{u} & 1 & 0 \\ (\gamma - 1)\tilde{u}^2/(2\tilde{c}^2) & -(\gamma - 1)\tilde{u} & \gamma - 1 \end{pmatrix}$$

We can also write

$$\tilde{r} = -|\tilde{A}| \cdot \begin{pmatrix} s_i - s_{i-1} \\ \rho^*(u_i - u_{i-1}) \\ p_i - p_{i-1} \end{pmatrix}$$
or
\[(46) \quad \tilde{r} = \text{sign}(\tilde{A}) r\]

It is evident from (43) and (45) that the matrix of right eigenvectors of \(\tilde{A}\) is
\[\tilde{T} = C^{-1}_a \tilde{T}\]

or \(\tilde{T} = (\tilde{e}_1, \tilde{e}_2, \tilde{e}_3)\) where
\[(47) \quad \tilde{e}_1 = \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix}; \quad \tilde{e}_2 = \begin{pmatrix} 0 \\ -\tilde{c} \\ \tilde{c}^2 \end{pmatrix}; \quad \tilde{e}_3 = \begin{pmatrix} 0 \\ \tilde{c} \\ \tilde{c}^2 \end{pmatrix}\]

**Remark 3.1.** It is obvious from the structure of the matrix \(\tilde{T}\) that the auxiliary variable \(s\) coincides with the first element of the characteristic variable vector (32)
\[(48) \quad w_1 = s\]

Denote
\[M = \text{sign}(\tilde{A})\]

In order to make a computer program more efficient it is useful to write an explicit expression for the matrix \(M\). It is easy to see that in the supersonic case
\[(49) \quad M^{sup} = \text{sign}(\tilde{u}) \cdot I\]

where \(I\) is a \(3 \times 3\) unity matrix.

Some algebra reveals that in the subsonic case matrix \(\text{sign}(\tilde{A})\) has a very simple structure as well
\[(50) \quad M^{sub} = \begin{pmatrix} \text{sign}(\tilde{u}) & 0 & 0 \\ 0 & 0 & 1/\tilde{c} \\ 0 & \tilde{c} & 0 \end{pmatrix}\]

The second and third rows mean that the artificial diffusion added to the momentum equations is proportional to the fluctuation of the pressure equation and vice versa.

**Remark 3.2.** The auxiliary variables formulation (37) of the Euler equations is, perhaps, the simplest way to write the Euler equations. The usefulness of this formulation will become even more evident in §§4,6.

4. **Construction of the two-dimensional Euler scheme.** Euler equations of gas dynamics in two dimension can be written as follows
\[(51) \quad u_t + F(u)_x + G(u)_y = 0,\]

where
\[(52) \quad u = \begin{pmatrix} \rho \\ \rho u \\ \rho v \\ e \end{pmatrix}; \quad F(u) = \begin{pmatrix} \rho u \\ \rho u^2 + p \\ \rho uv \\ \rho uH \end{pmatrix}; \quad G(u) = \begin{pmatrix} \rho v \\ \rho uv \\ \rho v^2 + p \\ \rho vH \end{pmatrix}\]
where the enthalpy $H$ is defined by

$$
H = \frac{e + p}{\rho} = \frac{c^2}{\gamma - 1} + \frac{u^2 + v^2}{2},
$$

the speed of sound

$$
e = \sqrt{\frac{\gamma p}{\rho}}
$$

and the pressure

$$
p = (\gamma - 1)(e - \rho \frac{u^2 + v^2}{2})
$$

The quasilinear non-conservative formulation of the Euler system in auxiliary variables $(s, u, v, p)$ can be introduced in two dimensions as well

$$
\begin{align*}
s_t + u s_x + v s_y &= 0 \\
\rho u_t + \rho u u_x + \rho v u_y + p_x &= 0 \\
\rho v_t + \rho u v_x + \rho v v_y + p_y &= 0 \\
p_t + u p_x + v p_y + \rho c^2(u_x + v_y) &= 0
\end{align*}
$$

where $ds = d\rho - \frac{du}{\rho}$.  

**Remark 4.1.** Note that the entropy $(s)$ evolution is subject to the two-dimensional advection equation, which is locally decoupled from the rest of the system.

The fluctuation of the system (51) defined over the triangle $T$

$$
R = \int \int u_t = - \int \int (F_x + G_y) \, dx \, dy = - S_T [\hat{F}_x + \hat{G}_y]
$$

where $\hat{F}_x, \hat{G}_y$ are some averaged values of the flux derivatives over the triangle $T$.

Our construction of the truly two-dimensional Euler scheme utilizes the two-dimensional extension (Roe, Struijs and Deconinck [16]) of the Roe conservative linearization for one-dimensional case. Therefore, following the procedure developed in [16], we assume that the quantity which varies linearly over an element is the “parameter vector”

$$
\textbf{m} = \sqrt{\rho} [1, u, v, H]^T
$$

and its averaged value on the triangle $T$ is given by the following

$$
\bar{\textbf{m}} = \frac{\textbf{m}_1 + \textbf{m}_2 + \textbf{m}_3}{3}
$$

Roe-averaged quantities can be introduced

$$
\begin{align*}
\bar{u} &= \frac{\tilde{m}_2}{\bar{m}_1} \\
\bar{v} &= \frac{\tilde{m}_3}{\bar{m}_1} \\
\bar{H} &= \frac{\tilde{m}_4}{\bar{m}_1}
\end{align*}
$$

and

$$
\tilde{c}^2 = (\gamma - 1)[\bar{H} - \frac{1}{2}(\bar{u}^2 + \bar{v}^2)]
$$
Fluctuations of the Euler system in the auxiliary variables can be presented as

\begin{equation}
\mathbf{r} = \mathbf{r}^x + \mathbf{r}^y,
\end{equation}

where

\begin{align*}
\mathbf{r}^x &= -S_T \mathbf{A} \cdot (\hat{\mathbf{u}}^x, \hat{\mathbf{v}}^x)^T \\
\mathbf{r}^y &= -S_T \mathbf{B} \cdot (\hat{\mathbf{u}}^y, \hat{\mathbf{v}}^y)^T
\end{align*}

with

\begin{align*}
\mathbf{A} &= \begin{pmatrix}
\bar{u} & 0 & 0 & 0 \\
0 & \bar{u} & 0 & 1 \\
0 & 0 & \bar{u} & 0 \\
0 & \bar{c}^2 & 0 & \bar{u}
\end{pmatrix}, &
\mathbf{B} &= \begin{pmatrix}
\bar{v} & 0 & 0 & 0 \\
0 & \bar{v} & 0 & 0 \\
0 & 0 & \bar{v} & 1 \\
0 & 0 & \bar{c}^2 & \bar{v}
\end{pmatrix}
\end{align*}

and $S_T = h^2/2$ is the area of the triangle $T$, and

\begin{align*}
\hat{\mathbf{u}}^x &= 2\bar{m}_1(m_1)_x \\
\hat{\mathbf{u}}^y &= \bar{m}_1(m_2)_x - \bar{m}_2(m_1)_x \\
\hat{\mathbf{p}}^x &= \bar{m}_1(m_3)_x - \bar{m}_3(m_1)_x \\
\hat{\mathbf{p}}^y &= \gamma^{-1}[\bar{m}_1(m_4)_x + \bar{m}_1(m_1)_x + (\bar{m}_2(m_2)_x + \bar{m}_3(m_3)_x)]
\end{align*}

The corresponding terms involving derivatives in $y$ direction can be written in the analogous manner.

Introducing the matrix

\begin{equation}
\mathbf{C}_a = \begin{pmatrix}
1 & 0 & 0 & 1/\bar{c}^2 \\
\bar{u} & 1 & 0 & \bar{u}/\bar{c}^2 \\
\bar{v} & 0 & 1 & \bar{v}/\bar{c}^2 \\
(\bar{u}^2 + \bar{v}^2)/2 & \bar{u} & \bar{v} & 1/(\gamma - 1) + (\bar{u}^2 + \bar{v}^2)/(2\bar{c}^2)
\end{pmatrix}
\end{equation}

we can define

\begin{align*}
\mathbf{R}^x &= \mathbf{C}_a \mathbf{r}^x \\
\mathbf{R}^y &= \mathbf{C}_a \mathbf{r}^y
\end{align*}

It can be easily verified that

\begin{align*}
\mathbf{R}^x &= -S_T \mathbf{F}_x^v \\
\mathbf{R}^y &= -S_T \mathbf{G}_y^v
\end{align*}

where $\mathbf{F}_x^v, \mathbf{G}_y^v$ are the same averaged flux derivative values as defined in [16]. It is also obvious that the entire fluctuation

\begin{equation}
\mathbf{R} = \mathbf{R}^x + \mathbf{R}^y = \mathbf{C}_a (\mathbf{r}^x + \mathbf{r}^y) = \mathbf{C}_a \mathbf{r}
\end{equation}

Consider triangle $T$ as illustrated on Fig.2. The fluctuation is distributed according to the following formulae:

\begin{align*}
S \mathbf{u}^{n+1}_1 &= S \mathbf{u}^n_1 + \bar{\mathbf{C}}_a (\mathbf{r}^x - \bar{\mathbf{r}}^x) \\
S \mathbf{u}^{n+1}_2 &= S \mathbf{u}^n_2 + \bar{\mathbf{C}}_a [(\mathbf{r}^x + \bar{\mathbf{r}}^x) + (\mathbf{r}^y - \bar{\mathbf{r}}^y)] \\
S \mathbf{u}^{n+1}_3 &= S \mathbf{u}^n_3 + \bar{\mathbf{C}}_a (\mathbf{r}^y + \bar{\mathbf{r}}^y)
\end{align*}
Defining

\[
\begin{align*}
\bar{r}^x &= \text{sign}(\bar{A})r^x \\
\bar{r}^y &= \text{sign}(\bar{B})r^y
\end{align*}
\]

we obtain the scheme that is similar to the standard Roe dimensionally split scheme. The only difference is in the linearization procedure.

We can construct now a (linearity preserving) second order accurate scheme. First, we shall introduce vectors \(r^x, r^y\) with their elements defined by

\[
\begin{align*}
\bar{r}^x_i &= \bar{r}^x_i + \Psi(q_i) \bar{r}^y_i \\
\bar{r}^y_i &= \bar{r}^y_i + \Psi(q_i) \bar{r}^x_i
\end{align*}
\]

for \(i = 1, 2, 3, 4\), where

\[
q_i = \frac{r_i^x}{r_i^y}
\]

and \(\Psi\) is a (non-compressive) limiter.

Substituting \(r^x, r^y\) for \(r^x, r^y\) in (71) and (72) we obtain a linearity preserving (second order accurate in this case) scheme. This is because if

\[r = 0\]

then

\[r^x = r^y = 0\]

as well. Therefore, the update of any variable in all the three vertices of the triangle \(T\) due to the fluctuation on this triangle is zero.

The resulting scheme is also conservative since

\[r \equiv r^x + r^y \equiv r^x + r^y\]

Denote

\[
M_x = \text{sign}(\bar{A}) \\
M_y = \text{sign}(\bar{B})
\]

It is interesting to note that

\[
M_x = \begin{cases} 
M^{\text{sub}}_x, & \text{if } |\bar{u}| \leq \bar{c} \\
M^{\text{sup}}_x, & \text{if } |\bar{u}| > \bar{c}
\end{cases}
\]

and

\[
M_y = \begin{cases} 
M^{\text{sub}}_y, & \text{if } |\bar{v}| \leq \bar{c} \\
M^{\text{sup}}_y, & \text{if } |\bar{v}| > \bar{c}
\end{cases}
\]

where

\[
M^{\text{sub}}_x = \begin{pmatrix} 
\text{sign}(\bar{u}) & 0 & 0 & 0 \\
0 & 0 & 0 & 1/\bar{c} \\
0 & 0 & \text{sign}(\bar{u}) & 0 \\
0 & \bar{c} & 0 & 0
\end{pmatrix},
\]

\[
M^{\text{sup}}_x = \begin{pmatrix} 
\text{sign}(\bar{u}) & 0 & 0 & 0 \\
0 & 0 & 0 & 1/\bar{c} \\
0 & 0 & \text{sign}(\bar{u}) & 0 \\
0 & \bar{c} & 0 & 0
\end{pmatrix},
\]

\[
M^{\text{sub}}_y = \begin{pmatrix} 
\text{sign}(\bar{v}) & 0 & 0 & 0 \\
0 & 0 & 0 & 1/\bar{c} \\
0 & 0 & \text{sign}(\bar{v}) & 0 \\
0 & \bar{c} & 0 & 0
\end{pmatrix},
\]

\[
M^{\text{sup}}_y = \begin{pmatrix} 
\text{sign}(\bar{v}) & 0 & 0 & 0 \\
0 & 0 & 0 & 1/\bar{c} \\
0 & 0 & \text{sign}(\bar{v}) & 0 \\
0 & \bar{c} & 0 & 0
\end{pmatrix}.
\]
\[ M_{y}^{\text{sub}} = \begin{pmatrix} \text{sign}(\tilde{v}) & 0 & 0 & 0 \\ 0 & \text{sign}(\tilde{v}) & 0 & 0 \\ 0 & 0 & 0 & 1/\tilde{c} \\ 0 & 0 & \tilde{c} & 0 \end{pmatrix}, \]

and

\[ M_{x}^{\text{sub}} = \text{sign}(\tilde{u}) I, \]

\[ M_{y}^{\text{sub}} = \text{sign}(\tilde{v}) I. \]

5. General unstructured grid formulation. Consider an unstructured triangular grid covering out domain and triangle \( T \) belonging to this grid (see Fig.4). Denote \( h_i \) length of the \( i \)th face of this triangle, \( \tilde{e}_i \) a unit vector along the \( i \)th face in clockwise direction. Denote also \( \tilde{n}_i \) a unit inward normal to the \( i \)th face and \( S_T \) area of the triangle \( T \). In this section we shall describe first the general (unstructured grid) version of fluctuation-splitting advection scheme. Then we shall construct the genuinely two-dimensional numerical scheme for the compressible Euler system, also formulated for the unstructured meshes.

5.1. Advection scheme. Consider a linear constant coefficient advection equation

\[ u_t + \vec{\lambda} \cdot \nabla u = 0 \]

Consider a non-orthogonal coordinate system \( \xi, \eta \) aligned with the vectors \( e_1, e_2 \) (see Fig.4) and introduce the following quantities

\[ \alpha = \frac{\vec{\lambda} \cdot \tilde{n}_2}{\theta}, \quad \beta = \frac{\vec{\lambda} \cdot \tilde{n}_1}{\theta} \]

where

\[ \theta = \tilde{e}_1 \cdot \tilde{n}_2 \equiv \tilde{e}_2 \cdot \tilde{n}_1. \]

Then Eq.(81) can be written in the coordinate system \( \xi, \eta \)

\[ u_t + \alpha u_\xi + \beta u_\eta = 0 \]

The fluctuation of the Eq.(81)

\[ R = R^\xi + R^\eta, \]

where

\[ R^\xi = -S_T [\alpha (u_3 - u_1)/h_1] \]

\[ R^\eta = -S_T [\beta (u_2 - u_3)/h_2] \]

The fluctuation distribution formulae

\[ S_{1} u_1^{n+1} = S_{1} u_1^{n} + \frac{\tau}{2} (R^\xi - \overline{R^\xi}) \]

\[ S_{2} u_2^{n+1} = S_{2} u_2^{n} + \frac{\tau}{2} (R^\eta + \overline{R^\eta}) \]

\[ S_{3} u_3^{n+1} = S_{3} u_3^{n} + \frac{\tau}{2} [(R^\xi + \overline{R^\xi}) + (R^\eta - \overline{R^\eta})] \]
with the artificial viscosity terms defined as follows

\[ R^\xi = \text{sign}(\alpha) R^\xi \]
\[ R^\nu = \text{sign}(\beta) R^\nu \]

result in a positive type upwind scheme. Introduce the following quantity

\[ Q = -\frac{R^\xi}{R^\nu} \]

Define

\[ R^{\xi^*} = R^\xi + R^\nu \Psi(Q) \]
\[ R^{\nu^*} = R^\nu + R^\xi \frac{\Psi(Q)}{Q} \]

and substituting \( R^{\xi^*}, R^{\nu^*} \) instead of \( R^\xi, R^\nu \) in (87), (88). Using the identity

\[ R^\nu \Psi(Q) \equiv -R^\xi \frac{\Psi(Q)}{Q} \]

we can rewrite \( R^{\xi^*}, R^{\nu^*} \) in the following form

\[ R^{\xi^*} = R^\xi (1 - \frac{\Psi(Q)}{Q}) \]
\[ R^{\nu^*} = R^\nu (1 - \Psi(Q)) \]

it is easy to verify that the resulting scheme is positive if

\[ 0 \leq \Psi(Q) \leq 1, \quad 0 \leq \frac{\Psi(Q)}{Q} \leq 1 \]

and linearity preserving if

\[ \Psi(1) = 1 \]

Note also that

\[ R = R^{\xi^*} + R^{\nu^*} = R^\xi + R^\nu. \]

Therefore, the constructed scheme is conservative.

There are two differences between the formulated scheme and the typical fluctuation splitting advection schemes (see [6],[22],[19])

1. no distinction is made between triangles with two outflow faces (Type I) and one outflow face (Type II)
   For the advection problem this implies more computational work since limiter function has to be evaluated on all the triangles (not only on those of Type II). However, for the Euler system no significant savings can be made by this distinction, since limiters have to be used in on all the triangles anyway (see §5.2).

2. the derivatives are approximated by finite differences along the faces which were chosen arbitrarily and are not necessarily both inflow or outflow (\( \alpha \) and \( \beta \) are not necessarily of the same sign).

In case of the advection equation choice of the faces which are both either inflow or outflow for derivative approximation provides better resolution of discontinuities. For the systems, however, the question of the optimal choice is more complex (see remark in §8). Therefore, we presented here the construction of the advection scheme with no assumption made about the signs of \( \alpha \) and \( \beta \).
5.2. Euler system. The auxiliary variable formulation of the Euler system can be written in the following vector form

\[ s_t + \vec{U} \cdot \nabla s = 0 \]
\[ \rho \vec{U}_t + \rho \vec{U} \cdot \nabla \vec{U} + \nabla p = 0 \]
\[ p_t + \vec{U} \cdot \nabla p + \rho c^2 \nabla \cdot \vec{U} = 0 \]

where \( \vec{U} = (u, v) \)

Consider again triangle \( T \) on Fig.4 and the non-orthogonal coordinate system \((\xi, \eta)\) aligning with two of the faces of this triangle (or the unit vectors \( \vec{e}_1, \vec{e}_2 \)) Define the following quantities

\[ \mathcal{U} = \vec{U} \cdot \vec{e}_2, \quad \mathcal{V} = \vec{U} \cdot \vec{e}_1. \]

and

\[ \alpha = \frac{\vec{U} \cdot \vec{n}_1}{\theta}, \quad \beta = \frac{\vec{U} \cdot \vec{n}_2}{\theta}. \]

We can rewrite the Euler system (96) in this new non-orthogonal coordinates \((\xi, \eta)\)

\[ s_t + \alpha s_\xi + \beta s_\eta = 0 \]
\[ \rho \mathcal{U}_t + \rho \alpha \mathcal{U}_\xi + \rho \beta \mathcal{U}_\eta + p_\xi = 0 \]
\[ \rho \mathcal{V}_t + \rho \alpha \mathcal{V}_\xi + \rho \beta \mathcal{V}_\eta + p_\eta = 0 \]
\[ p_t + \alpha p_\xi + \beta p_\eta + \rho c^2 (\alpha_\xi + \beta_\eta) = 0 \]

In order to compute the fluctuation of the system

\[ r = r^\xi + r^\eta \]

on a general triangle \( T \) we follow again the two-dimensional linearization procedure presented in [16] and assume the quantity varying linearly on the triangle is the parameter vector

\[ \mathbf{m} = \sqrt{\rho} (1, u, v, H)^T \]

and its averaged value on the triangle \( T \) is given by the following

\[ \overline{\mathbf{m}} = \frac{\mathbf{m}_1 + \mathbf{m}_2 + \mathbf{m}_3}{3} \]

Then (similarly to the structured grid case)

\[ r^\xi = -S_T \begin{pmatrix} \hat{s}_\xi \\ \hat{\rho}_\xi \mathcal{U}_\xi + \hat{\rho}_\xi \\ \hat{\rho}_\xi \mathcal{V}_\xi + \hat{\rho}_\xi \\ \hat{\rho}_\xi + c^2 \hat{\rho}_\xi \end{pmatrix} \]

where

\[ \hat{\rho}_\xi = 2 \overline{m}_1 (m_1)_\xi \]
\[ \hat{\rho}_\xi = \frac{\gamma - 1}{\gamma} [ (\overline{m}_4 (m_1)_\xi + \overline{m}_1 (m_4)_\xi) + \overline{m}_2 (m_2)_\xi + \overline{m}_3 (m_3)_\xi ] \]
\[ \hat{s}_\xi = \hat{\rho}_\xi - c^2 \hat{\rho}_\xi \]
and denoting \( r^0 \) can be evaluated in a similar way. Defining the following set of conservative variables

\[
\vec{u} = \begin{pmatrix} \rho \\ \rho \mathcal{u} \\ \rho \mathcal{V} \\ e \end{pmatrix}
\]

and denoting \( \bar{R} \) the fluctuations of the Euler system in these variables on triangle \( T \), it can be easily verified that the fluctuations in the following relation holds

\[
\bar{R} = C_a \cdot r
\]

where

\[
C_a = \begin{pmatrix} 1 & 0 & 0 & 1/\tilde{c}^2 \\ \tilde{U} & 1 & 0 & \tilde{U}/\tilde{c}^2 \\ \tilde{V} & 0 & 1 & \tilde{V}/\tilde{c}^2 \\ \tilde{U}^2/2 & \tilde{\alpha} & \tilde{\beta} & 1/(\gamma - 1) + \tilde{U}^2/(2\tilde{c}^2) \end{pmatrix}
\]

The fluctuation distribution formulae

\[
\begin{align*}
S_1 u_1^{n+1} &= S_1 u_1^n + \tilde{\tau} C_a (r^\xi - \bar{r}^\xi) \\
S_2 u_2^{n+1} &= S_2 u_2^n + \tilde{\tau} C_a (r^\eta + \bar{r}^\eta) \\
S_3 u_3^{n+1} &= S_3 u_3^n + \tilde{\tau} C_a [(r^\xi + \bar{r}^\xi) + (r^\eta - \bar{r}^\eta)]
\end{align*}
\]

will result in an upwind scheme provided we define the artificial viscosity terms \( r^\xi, r^\eta \).

However, before doing this we would like to rewrite (111) for the update of the “regular” conservative variables \( \mathbf{u} = (\rho, \rho \mathcal{u}, \rho \mathcal{V}, e)^T \). Note that

\[
\mathbf{u} = \Theta \cdot \dot{\mathbf{u}}
\]

where

\[
\Theta = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & n_1^\gamma / \theta & n_1^\eta / \theta & 0 \\ 0 & n_2^\gamma / \theta & n_2^\eta / \theta & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}
\]

Introducing the following matrix

\[
C_a^\theta = \Theta \cdot C_a
\]

we obtain the fluctuation distribution formulae for the “regular” conservative variables

\[
\begin{align*}
S_1 u_1^{n+1} &= S_1 u_1^n + \tilde{\tau} C_a^\theta (r^\xi - \bar{r}^\xi) \\
S_2 u_2^{n+1} &= S_2 u_2^n + \tilde{\tau} C_a^\theta (r^\eta + \bar{r}^\eta) \\
S_3 u_3^{n+1} &= S_3 u_3^n + \tilde{\tau} C_a^\theta [(r^\xi + \bar{r}^\xi) + (r^\eta - \bar{r}^\eta)]
\end{align*}
\]
The relationship between the artificial viscosity and the fluctuations is given by

\begin{align}
\vec{r}^\xi &= M_\xi \vec{r}^\xi \\
\vec{r}^\eta &= M_\eta \vec{r}^\eta
\end{align}

where

\begin{align}
M_\xi &= \begin{cases} 
M_\xi^{\text{sub}}, & \text{if } |\tilde{\alpha}| \leq \tilde{c} \\
M_\xi^{\text{sup}}, & \text{if } |\tilde{\alpha}| > \tilde{c},
\end{cases} \\
M_\eta &= \begin{cases} 
M_\eta^{\text{sub}}, & \text{if } |\tilde{\beta}| \leq \tilde{c} \\
M_\eta^{\text{sup}}, & \text{if } |\tilde{\beta}| > \tilde{c},
\end{cases}
\end{align}

and

\begin{align}
M_\xi^{\text{sub}} &= \begin{pmatrix} \text{sign}(\tilde{\alpha}) & 0 & 0 & 0 \\
0 & 0 & 0 & 1/\tilde{c} \\
0 & 0 & \text{sign}(\tilde{\alpha}) & 0 \\
0 & \tilde{c} & 0 & 0
\end{pmatrix}, \\
M_\eta^{\text{sub}} &= \begin{pmatrix} \text{sign}(\tilde{\beta}) & 0 & 0 & 0 \\
0 & \text{sign}(\tilde{\beta}) & 0 & 0 \\
0 & 0 & 0 & 1/\tilde{c} \\
0 & 0 & \tilde{c} & 0
\end{pmatrix},
\end{align}

and

\begin{align}
M_\xi^{\text{sup}} &= \text{sign}(\tilde{\alpha})I, \\
M_\eta^{\text{sup}} &= \text{sign}(\tilde{\beta})I.
\end{align}

A linearity preserving scheme can be constructed by introducing the vectors \( \vec{r}^\xi, \vec{r}^\eta \) with their elements defined by

\begin{align}
r_i^{\xi^*} &= \vec{r}_i^\xi + \Psi(q_i) r_i^\eta \\
r_i^{\eta^*} &= r_i^\eta + \Psi(q_i) \vec{r}_i^\xi
\end{align}

for \( i = 1, 2, 3, 4 \), where

\begin{align}
q_i = -\frac{r_i^\xi}{r_i^\eta}
\end{align}

and substituting them instead of \( \vec{r}^\xi, \vec{r}^\eta \) respectively in (115),(116).

**Remark 5.1.** In order to construct a non-oscillatory linearity preserving scheme for the Euler equations, derivatives can be approximated along any two out of three faces of the triangle. However, the resolution of such features of the flow as shocks, contact discontinuities and shear layers can be affected by the particular choice (see §8). Shocks are being resolved better (i.e. are represented by sharper numerical layers) if the numerical derivatives are computed along those two faces of the triangle which are the closest to the direction of the shock. The same is true for the shear layers and contact discontinuities, although the two faces closest to the discontinuity direction in this case will also be either two inflow or outflow faces of the triangle.
6. Outline of the extension to three dimensions. A detailed description of the three-dimensional schemes both for the scalar advection and Euler system will be given elsewhere. In this paper we only outline briefly their construction in the case of structured Cartesian grids. Each cube having grid nodes as its vertices can be divided into two prisms. The prism can be divided into three tetrahedra each. Any of the obtained tetrahedra will have 3 of its edges parallel to \( x \), \( y \) and \( z \) axes respectively. We shall utilize this in this section to make the presentation free of the unnecessary details related to the non-orthogonal coordinate systems. The construction of the fluctuation-splitting schemes both for the scalar advection and the Euler system will be outlined for the case of the tetrahedron \( T \) as illustrated on Fig. 5.

6.1. Advection scheme in three dimensions. Consider a scalar constant coefficient advection equation in three dimensions

\[
\frac{\partial u}{\partial t} + a \frac{\partial u}{\partial x} + b \frac{\partial u}{\partial y} + c \frac{\partial u}{\partial z} = 0
\]

The fluctuation of this equation on the tetrahedron \( T \) (see Fig. 5), whose volume is \( V = h^3/6 \).

\[
R = R^x + R^y + R^z
\]

where

\[
R^x = -\frac{k^2}{h^3} [a(u_3 - u_4)] \\
R^y = -\frac{k^2}{h^3} [b(u_2 - u_3)] \\
R^z = -\frac{k^2}{h^3} [c(u_1 - u_2)]
\]

The fluctuation distribution formulae are given as follows

\[
V_n^{x+1} = V_n^x + \frac{3}{h^3} C_a (R^z + \bar{R}^z) \\
V_n^{y+1} = V_n^y + \frac{3}{h^3} C_a [(R^y + \bar{R}^y) + (R^z - \bar{R}^z)] \\
V_n^{z+1} = V_n^z + \frac{3}{h^3} C_a [(R^z + \bar{R}^z) + (R^y - \bar{R}^y)] \\
V_n^{+1} = V_n^+ + \frac{3}{h^3} C_a (R^x - \bar{R}^x)
\]

It is easy to see that the following choice of the artificial viscosity

\[
\bar{R}^x = \text{sign}(a) R^x \\
\bar{R}^y = \text{sign}(b) R^y \\
\bar{R}^z = \text{sign}(c) R^z
\]

results in a regular upwind scheme.

Introducing the following quantities

\[
Q^x = \frac{[R^y]^+ + [R^z]^+}{R^x + [R^y]^+ + [R^z]^+} \\
Q^y = \frac{[R^z]^+ + [R^z]^+}{R^y + [R^z]^+ + [R^z]^+} \\
Q^z = \frac{[R^x]^+ + [R^y]^+}{R^z + [R^x]^+ + [R^y]^+}
\]

18
where
\[(131)\quad [R_i^\alpha]_R^+ = \begin{cases} R_i^\alpha, & \text{if sign}(R_i^\alpha) = \text{sign}(R^\kappa), \\ 0, & \text{otherwise}, \end{cases} \]
and
\[(132)\quad [R_i^\kappa]_R^- = \begin{cases} 0, & \text{if sign}(R_i^\kappa) = \text{sign}(R^\kappa), \\ -R_i^\kappa, & \text{otherwise}. \end{cases} \]
or
\[(133)\quad [R_i^\kappa]_R^- = [R_i^\alpha]_R^+ - R_i^\kappa \]
where \(\iota\) and \(\kappa\) stand for one of (though different) \(x, y\) or \(z\) each.

Then we define the following quantities
\[(134)\quad \begin{align*}
R_i^x &= R_i^\alpha + \Psi(Q^y) R_i^y + \Psi(Q^z) R_i^z \\
R_i^y &= R_i^\alpha + \Psi(Q^x) R_i^x + \Psi(Q^z) R_i^z \\
R_i^z &= R_i^\alpha + \Psi(Q^x) R_i^x + \Psi(Q^y) R_i^y
\end{align*} \]
where \(\Psi\) is a non-compressive limiter.

Substituting \(R_i^x, R_i^y, R_i^z\) into (128),(129) instead of \(R_i^x, R_i^y, R_i^z\) respectively we obtain a linearity preserving (second order accurate in this case) positive advection scheme.

To demonstrate this we can assume without loss of generality that
\[(135)\quad \begin{align*}
Q^y \cdot Q^z &\geq 0 \\
Q^x(Q^y + Q^z) &\leq 0
\end{align*} \]
Then
\[(136)\quad \begin{align*}
Q^y &= -R^x/(R^y + R^z) \\
Q^x &\equiv 1/Q^y \\
Q^z &\equiv Q^y
\end{align*} \]
In this case
\[(137)\quad \begin{align*}
\Psi(Q^y) R^y + \Psi(Q^z) R^z &\equiv -\Psi(1/Q^x) R^x \\
\Psi(Q^x) R^x &\equiv -\Psi(Q^y)(R^y + R^z)
\end{align*} \]
and therefore
\[(138)\quad \begin{align*}
R_i^x^* &= (1 - \Psi(1/Q^x)) R_i^x \\
R_i^y^* &= (1 - \Psi(Q^y)) R_i^y \\
R_i^z^* &= (1 - \Psi(Q^z)) R_i^z
\end{align*} \]
It can be concluded that if \(\Psi\) is a non-compressive limiter, then the constructed scheme is positive.

If the fluctuation \(R\) vanishes then
\[(139)\quad R^x = R^y + R^z \]
and, therefore,
\[(140)\quad Q^y = Q^y = Q^z = 1.\]
Then it is easy to see that
\[(141)\quad R_i^x^* = R_i^y^* = R_i^z^* = 0, \]
provided \(\Psi(1) = 1\), i.e. the constructed scheme is linearity preserving.
6.2. Euler system. Euler equations in three dimensions

\[
\begin{align*}
&\mathbf{u}_t + \mathbf{F}(\mathbf{u})_x + \mathbf{G}(\mathbf{u})_y + \mathbf{H}(\mathbf{u})_z = \mathbf{0}
\end{align*}
\]

where

\[
\mathbf{u} = \begin{pmatrix} \rho \\ \rho u \\ \rho v \\ \rho w \\ e \end{pmatrix};
\]

\[
\mathbf{F}(\mathbf{u}) = \begin{pmatrix} \rho u \\ \rho u^2 + p \\ \rho uv \\ \rho uw \\ u(e + p) \end{pmatrix};
\]

\[
\mathbf{G}(\mathbf{u}) = \begin{pmatrix} \rho v \\ \rho uv \\ \rho v^2 + p \\ \rho vw \\ v(e + p) \end{pmatrix};
\]

\[
\mathbf{H}(\mathbf{u}) = \begin{pmatrix} \rho w \\ \rho uw \\ \rho vw \\ \rho w^2 + p \\ w(e + p) \end{pmatrix}.
\]

Introducing the auxiliary variables \((s, u, v, w, p)\) we can rewrite these equations in the following non-conservative form

\[
\begin{align*}
&s_t + u s_x + v s_y + w s_z = 0 \\
&\rho u_t + \rho u u_x + \rho uv_y + \rho uw_z + p_x = 0 \\
&\rho v_t + \rho u v_x + \rho uv_y + \rho vw_z + p_y = 0 \\
&\rho w_t + \rho u w_x + \rho vw_y + \rho w^2 + p_z = 0 \\
&p_t + u p_x + v p_y + w p_z + \rho e^2 (u_x + v_y + w_z) = 0
\end{align*}
\]

Fluctuation on tetrahedron \(T\) (see Fig.5) is

\[
\mathbf{R} = \int \int \int \mathbf{u}_t = -\int \int \int (\mathbf{F}_x + \mathbf{G}_y + \mathbf{H}_z) dx dy dz
\]

\[
= -V_T [\tilde{\mathbf{F}}_x + \tilde{\mathbf{G}}_y + \tilde{\mathbf{H}}_z]
\]

Fluctuation in auxiliary variables on each tetrahedron can be represented as a sum of three parts

\[
\mathbf{r} = \mathbf{r}^x + \mathbf{r}^y + \mathbf{r}^z
\]

The matrix \(C_a\) relating the fluctuations in conservative variables \(\mathbf{R}\) to those in the auxiliary variables

\[
\begin{pmatrix}
1 & 0 & 0 & 0 & 1/\hat{c}^2 \\
\bar{u} & 1 & 0 & 0 & \bar{u}/\hat{c}^2 \\
\bar{v} & 0 & 1 & 0 & \bar{v}/\hat{c}^2 \\
\bar{w} & 0 & 0 & 1 & \bar{w}/\hat{c}^2 \\
\bar{U}^2/2 & \bar{u} & \bar{v} & \bar{w} & 1/(\gamma - 1) + \bar{U}^2/(2\hat{c})
\end{pmatrix}
\]

It was pointed out in [16] that the two-dimensional conservative linearization presented there extends to three dimensions in a straightforward way. Again, we assume that the quantity that varies linearly on the tetrahedron \(T\) is the “parameter-vector” and
the averaged quantities can be defined in a manner similar to the two-dimensional case. The fluctuation in the auxiliary variables on $T$ can be written as follows

\begin{equation}
\mathbf{r} = -S_T \cdot \mathbf{A} \cdot \mathbf{r}^e = -(S_T \mathbf{A} \cdot (\tilde{s}_x, \tilde{\rho}_x, \tilde{\rho}_y, \tilde{\rho}_z, \tilde{\rho}_w, \tilde{\rho}_v))^T
\end{equation}

The fluctuation distribution formulae in this case are

\begin{align}
V u_1^{n+1} &= V u_1^n + \frac{1}{2} C_u (r_x^e + \tilde{r}_x^e) \\
V u_2^{n+1} &= V u_2^n + \frac{1}{2} C_u (r_y^e + \tilde{r}_y^e) + (r_x^e - \tilde{r}_x^e) \\
V u_3^{n+1} &= V u_3^n + \frac{1}{2} C_u (r_z^e + \tilde{r}_z^e) + (r_y^e - \tilde{r}_y^e) \\
V u_4^{n+1} &= V u_4^n + \frac{1}{2} C_u (r_v^e - \tilde{r}_v^e)
\end{align}

Similarly to the two-dimensional case, the relationship between the artificial viscosity needed in $x$-direction to obtain the upwind scheme and $\mathbf{r}^e$ is the following

\begin{equation}
\tilde{r}_x^e = \text{sign}(\tilde{A}) r_x^e.
\end{equation}

$\tilde{r}_y^e$ and $\tilde{r}_z^e$ can be evaluated in a similar way.

Denoting

\[ M_x = \text{sign}(\tilde{A}) \]

it can be verified that

\begin{equation}
M_x = \begin{cases}
M_x^{\text{sub}}, & \text{if } |\tilde{u}| \leq \tilde{c} \\
M_x^{\text{sup}}, & \text{if } |\tilde{u}| > \tilde{c},
\end{cases}
\end{equation}

where

\begin{equation}
M_x^{\text{sub}} = \begin{pmatrix}
\text{sign}(\tilde{u}) & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 1/\tilde{c} \\
0 & 0 & \text{sign}(\tilde{u}) & 0 & 0 \\
0 & 0 & 0 & \text{sign}(\tilde{u}) & 0 \\
0 & \tilde{c} & 0 & 0 & 0
\end{pmatrix}
\end{equation}

and

\begin{equation}
M_x^{\text{sup}} = \text{sign}(\tilde{u}) I
\end{equation}

Following the procedure of constructing a high resolution scalar advection scheme in three dimensions, presented briefly in §6.1 we define the following quantities

\begin{equation}
q_x^v = \frac{[r_x^v]_x^e + [r_y^v]_x^e}{[r_x^v]_x^e + [r_y^v]_x^e + [r_z^v]_x^e}
\end{equation}

\begin{equation}
q_y^v = \frac{[r_x^v]_y^e + [r_y^v]_y^e}{[r_x^v]_y^e + [r_y^v]_y^e + [r_z^v]_y^e}
\end{equation}

\begin{equation}
q_z^v = \frac{[r_x^v]_z^e + [r_y^v]_z^e}{[r_x^v]_z^e + [r_y^v]_z^e + [r_z^v]_z^e}
\end{equation}
where $\ldots \pm, \ldots \pm, \ldots \pm$ are defined by (131),(132). Now we can introduce

\begin{align}
\mathbf{r}^x_i &= \mathbf{r}^x_i + \Psi(q_i^x) r_i^x + \Psi(q_i^z) r_i^z \\
\mathbf{r}^y_i &= \mathbf{r}^y_i + \Psi(q_i^y) r_i^y + \Psi(q_i^z) r_i^z \\
\mathbf{r}^z_i &= \mathbf{r}^z_i + \Psi(q_i^z) r_i^z + \Psi(q_i^y) r_i^y
\end{align}

(156)

for $i = 1, \ldots , 5$.

Substituting $r^x, r^y, r^z$ instead of $r^x, r^y, r^z$ into the fluctuation distribution formulae (148) and (149) we obtain a linearity preserving (second order accurate for the case of structured meshes) genuinely three-dimensional scheme for the Euler equations.

Note that

\begin{align}
\mathbf{r} \equiv \mathbf{r}^x + \mathbf{r}^y + \mathbf{r}^z \equiv \mathbf{r}^{x'} + \mathbf{r}^{y'} + \mathbf{r}^{z'}.
\end{align}

(157)

Therefore, the constructed scheme is conservative. It is also easy to see that it is linearity preserving.

7. Multigrid solver. One of the most attractive properties of the constructed multidimensional scheme for the Euler equations is that the Collective Gauss-Seidel relaxation is stable when applied directly to the high-resolution discrete equations. This can be utilized to construct a very simple and efficient steady-state multigrid solver. In this work we would like just to illustrate the basic advantages of the multigrid solver that uses the constructed multidimensional scheme. Therefore, we do not discuss here any issues concerning the multigrid algorithm for general unstructured meshes, but address the interested reader to the literature (see, for instance, [11]).

We shall present briefly in this section the simple multigrid algorithm used in the numerical experiments presented in this work.

Description of the algorithm. The multigrid cycle used in this work is $W$-cycle and the entire algorithm can be implemented either as Cycling or as Full Multigrid (FMG).

Relaxation. The algorithm employs the Collective Gauss-Seidel relaxation as a smoother. In order to update the solution at each node a system of four nonlinear equations has to be solved. This can be done using the Newton method. One iteration at each node is sufficient for this purpose (see [18] for the discussion on this matter). The ordering of the relaxation can be Red-Black, lexicographic etc.

Restriction and prolongation. Assume that we have a hierarchical sequence of triangular grids, i.e. that any triangle on the coarser grid is a union of four triangles on the finer grid. The natural choice for prolongation in this case would be a linear interpolation along each face of the triangle belonging to the coarser grid. The restriction in this case can be just combining the fluctuations from the four finer grid triangles forming the coarse grid one. However, we consider only Cartesian grids in the numerical experiments presented in this work (see Figs.2,3). In this case we can use more conventional prolongation and restriction operators: bilinear correction interpolation and Full-Weighting of the residuals (see [1]). Term “residual” is used here in its usual sense: residual of the discrete equation at each gridpoint (constructed of the contributions from the triangles having this gridpoint as a common vertex).
Previous relevant results. Application of multigrid methods for the advection equation was studied in details in [17],[18] in conjunction with the genuinely two-dimensional control-volume type scheme developed there. It was demonstrated there that applying $2FMG-W(2, 1)$ algorithm is sufficient to obtain high quality solutions (i.e. solutions with sharply resolved discontinuities and second order accuracy both in smooth regions and in discontinuity location) for the advection equation. Many of the conclusions of [17],[18] apply directly to the Euler system case considered in this work.

Efficiency of the multigrid solver for advection-dominated problems. It was shown in [1] that the residual reduction per multigrid cycle for an advection (dominated) problem cannot in general be better than $.75$ for the second order accurate discretization ($$.5$ for the first order). This is because the coarse grid provides only a fraction ($$.75$ or $$5$ respectively) of the needed correction for some components. The ability of the multigrid algorithm to achieve rate of convergence close to $$.75$ (for the second order accurate approximation) means that the obstacle towards achieving a better efficiency are not the smoothing properties of the relaxation but rather an insufficient coarse grid correction for certain components. (see §9.2.2 for further discussion on this issue).

8. Numerical experiments. The purpose of the numerical experiments reported in this section is to verify the robustness of the constructed scheme and the quality of the numerical solutions obtained by its means. Some preliminary experiments illustrating the performance of the multigrid algorithm that utilizes this scheme are presented as well.

8.1. Supersonic flow in a channel with a bump. The test case considered here is a supersonic (Mach=2.9) flow in channel with a circular bump. The bump is located at the lower wall of the channel at $1 \leq x \leq 2$, and its surface is a circular arch of $\pi/3$ and radius 1. Note that the actual shape of the domain is a rectangle. The influence of the bump on the flow is imposed through the boundary conditions: the velocity component normal to the surface of the bump at a certain location is being reflected.

The first experiment uses a grid of the size $200 \times 40$ points. The density contour plots of the steady-state solution are presented on Fig.6(a). The scheme used is the one given by (71),(72),(73) in §4 with the minmod limiter.

The second experiment presented on Fig.6(b) corresponds to the same settings, except that the grid is twice finer ($400 \times 80$ points). As it is expected, the grid refinement results in a better resolution of the flow features.

The third experiment (Fig.6(c)) is performed on the grid of the same size as the first one. However, the triangulation is as illustrated on Fig.3 and the scheme employed is constructed according to (115),(116),(123) in §5 and the derivatives are approximated using the diagonal and parallel to the $x$ direction faces of the triangles. Even though the grid is structured, the most essential feature of the unstructured grid formulation of the scheme - use of the non-orthogonal coordinate system is present.

The purpose of this experiment is to test the performance of such a scheme and to illustrate the effect of the scheme and triangulation on the resolution of discontinuities. It can be seen on Fig.6(c) that the shock reflected from the upper wall is resolved better than the stronger one that is incident to the upper wall. This is because for this scheme/grid combination discontinuities whose direction is close to the grid diagonal (upper-left to lower-right) will be resolved very well (in addition to those which are
close to the horizontal or vertical directions).

8.2. Transonic flow over a circular bump. The testcase considered here is a transonic flow (free-stream Mach= .9) over a flat wall with a bump (Fig.7). The surface of the bump is a circular arch of \( \pi/3 \) and radius 1 and its location is between \( 3.5 \leq x \leq 4.5 \). Again, in order to keep the experiments simple at this stage of work, the bump is treated the same way as in the previous experiments. The grid is \( 200 \times 200 \) points and the scheme used is presented in §4. The shock of the "fish-tail" shape can be clearly observed on Fig.7.

8.3. Low Mach number flow over a circular bump. Here we present a numerical experiment concerning a low Mach number (=.1) flow over a flat wall with a circular (arch of \( \pi/3 \) and radius 2) bump. Here as well as in the previous case the presence of the bump is imitated through the appropriate boundary conditions. The grid is \( 200 \times 200 \) points. The density contours of the steady-state solution are presented on Fig.8.

8.4. Multigrid algorithm. To illustrate the performance of the multigrid algorithm we consider here the well known testcase of a shock reflecting from a flat wall. The multigrid algorithm involves five grids (levels): the finest consists of \( 129 \times 33 \) points, the coarsest \( 9 \times 3 \) points.

The multigrid algorithm is based on the scheme presented in §4 used with the lexicographic Gauss-Seidel relaxation. The restriction and prolongation procedures are the standard Full Weighting of the residuals and bilinear correction interpolation. The first experiment of the first concerns performing one \( W(2,1) \) cycle. Fig.9(a) presents the initial guess and Fig.9(b) - the numerical solution obtained by one \( W(2,1) \) cycle. It is remarkable that such a little computational work is sufficient to make the reflected shock is clearly visible. The numerical solution to this problem obtained by \( 2FMG - W(2,1) \) algorithm is presented on Fig.9(c).

Note, that in this case the flow is aligned with the \( x \)-direction in the significant part of the domain. In this case the artificial viscosity in the cross-stream direction in the entropy and \( u \)-momentum equations (see §4) vanishes. Therefore, no smoothing can be obtained in \( y \)-direction in some components. A multigrid algorithm utilizing the time-stepping type relaxation can deal with such a situation only using the semi-coarsening technique. Our algorithm employs the Gauss-Seidel relaxation. Therefore, it offers a much simpler and more efficient treatment of this problem: relaxation with lexicographic ordering in the stream direction.

The rate of convergence observed in this testcase as well as in other simple experiments concerning variety of flow regimes is very close to .75 (see §5.7,9.2.2 for a discussion).

9. Discussion and conclusions.

9.1. Summary of the current work. A new two-dimensional high-resolution (at the steady-state) scheme for the compressible Euler equations was presented. It is triangle-based and can be formulated with the same degree of simplicity both on structured and unstructured grids. The main advantage of this scheme is that Gauss-Seidel relaxation can be applied directly to the resulting discrete equations. This allows to construct a simple and efficient multigrid steady-state solver.

A remarkable property of the constructed scheme is also its very compact stencil: it involves only the immediate neighbors of the point of interest.
A variety of the flow regimes (supersonic, transonic and low Mach number flow) were considered in the numerical experiments to verify the quality of the solutions obtained by means of the constructed scheme and to demonstrate the efficiency of the multigrid algorithm.

Generalization of this scheme to three dimensional tetrahedral meshes is presented briefly as well.

9.2. Future work.

9.2.1. Compressible Navier-Stokes equations. The extension of the constructed scheme to the case of compressible Navier-Stokes equations is straightforward. It is interesting to note that the artificial viscosity present in the momentum equations in the subsonic case contains already terms of the type \((u_x + v_y)_x\) and \((u_x + v_y)_y\) that appear in the physical viscosity of the compressible Navier-Stokes equations.

9.2.2. Further improvement of the multigrid efficiency. As it was mentioned in §7 the main obstacle towards the further improvement of the multigrid efficiency is the following fact: for the hyperbolic problems the coarse grid correction is not sufficient for certain error components.

This difficulty was already addressed in the literature and some techniques to improve the multigrid efficiency were developed in [2]. Therefore, one possibility is to adapt these techniques for our case - compressible Euler equations.

We shall mention here another way to deal with this difficulty. The steady-state compressible Euler equations in subsonic case are very similar from the mathematical point of view to the incompressible Euler equations – both problems are of the mixed elliptic-hyperbolic type.

There exist very efficient steady-state multigrid solvers for the incompressible flow equations, which rely on the primitive variables formulation (velocities and pressure). Most of them employ staggered grid discretization of the equations. A typical efficiency of such algorithms for a low Reynolds number case is comparable to that for the Poisson equation. Although the convergence rate deteriorates for the advection dominated (high Reynolds number) case, it may still be possible to recover the optimal efficiency by treating the advection factor in some special way (like relaxing in the flow direction). This is achieved due to a certain “separation” of the elliptic and hyperbolic factors of the equations in the treatment (see [1]).

However, extending this approach to the compressible Euler equations appeared to be a very difficult problem despite the similarity of the equations.

A canonical variable formulation of the Euler equations for both incompressible and compressible cases was suggested recently by Ta’asan [23]. This formulation facilitated the construction of the discrete scheme (using staggered grids) and of the relaxation procedure that separate a treatment of the advection and full-potential factors (see [24]). The resulting multigrid algorithm achieves a very good efficiency in subsonic case if the relaxation is performed in the flow direction.

One of the future directions is to modify the scheme presented in this work so that it will allow to achieve a similar efficiency for the case of triangular (non-staggered and, possibly, unstructured) grids. This may be possible because some very important similarities between the present scheme and the existing discretizations for the incompressible flow equations used in very efficient multigrid solvers (see, for instance, [1]) can be observed (see §9.3). The resulting discretization will rely on the primitive
rather then the canonical variables. The latter is crucial for the further generalization of the solver to the compressible Navier-Stokes equations.

9.2.3. Time-dependent problems. The constructed scheme is capable of producing high-resolution (second order accurate on the structured grids) steady-state solutions for the compressible Euler equations. A very natural way to extend this capability to the transient problems is to use a Lax-Wendroff type modification of the constructed scheme, i.e. to scale the artificial viscosity in such a way that it will cancel the time error of the forward Euler time-stepping due to the equation (or system of equations) being solved.

To illustrate this on the simple case of the two-dimensional advection consider the scheme for the structured grids presented in §2.1.2. The use of the following artificial viscosity

\[
\tilde{R}^x = \frac{\tau}{h} a R^x \\
\tilde{R}^y = \frac{\tau}{h} b R^y.
\]

(158)

instead of one given by (5) results in the high-resolution scheme (constructed by substituting \(R^x, R^y\) defined by (6) instead of \(\tilde{R}^x, \tilde{R}^y\)) that is second order accurate in time and space. However, it is easy to see that in in general this scheme is not of the positive type anymore (see also [6]).

For the case of the Euler system modifying the construction of the high-resolution scheme presented in §4 by substituting the artificial viscosity defined as follows

\[
\tilde{r}^x = \frac{\tau}{h} A r^x \\
\tilde{r}^y = \frac{\tau}{h} B r^y
\]

(159)

instead of (72), results in a Lax-Wendroff type scheme for the Euler system. However, the applicability of this scheme is restricted to the problems with with no strong shocks.

It is interesting to note that the two-dimensional schemes by Colella [3],[4], LeVeque [10], Radvogin [12] can be interpreted as the schemes of the Lax-Wendroff type. However, the nonlinear mechanism that enables them to deal with (strong) shocks relies on one-dimensional limiters and characteristic variables in \(x\) and \(y\) direction, which introduces an essential flavor of dimensional splitting.

The first step towards the construction of a genuinely multidimensional time-space accurate and robust Euler scheme should be to construct a positive time-space accurate scalar advection scheme of the type Lax-Wendroff type. This is one of the direction being currently investigated.

9.3. What is a truly multidimensional scheme ?. Perhaps, it will be easier to answer this question after the nonoscillatory time-space accurate multidimensional scheme for the compressible Euler equations is constructed. However, some attributes of the truly multidimensional schemes can be seen already on the example of the scheme constructed here.

One of the main characteristics of a truly multidimensional scheme for fluid dynamics is that the divergence operator (in the pressure equation, the auxiliary variables formulation of the Euler system (56) should be represented in a difference scheme as whole. This is not the case for the dimensionally split schemes. It can be clearly seen on the example of the dimensional upwinding scheme (71),(72) that terms \(u_x\) and
are separated (when contributing to the artificial viscosity of the momentum and pressure equations).

Consider the case of subsonic flow. In this case the fluctuation of the pressure equation contributes to the artificial diffusion of the momentum equations. Let us modify slightly the scheme constructed in §4, and compute the fluctuation of the pressure equation contributing to the artificial viscosity terms of the momentum equation according to the following

\[
\rho^* = \rho^* + \rho^*.
\]

The only difference between (160) and (73) is that the limiter function is set to unity. Although

\[
\rho^* + \rho^* = 2\rho^* \neq \rho^*.
\]

such a scheme is conservative, since (160) is used only in the artificial viscosity. This is because the role of the artificial viscosity can be interpreted as “redistribution” of the fluctuations split by the central scheme: to subtract a certain amount from one vertex of the triangle and to add the same amount to another vertex. This does not violate conservation, regardless of what amount has been “redistributed”.

Recall, that for some very popular schemes for incompressible flow computations (see, for instance, [1]) the residual of the continuity equation contributes to the velocities update in such a way that the discrete vorticity remains unchanged.

The “physical” meaning of this is that the change in (evolution of) the vorticity is only due to the residuals of the momentum equations, as one would expect.

“Mathematical” meaning of this fact is that the elliptic factor of the incompressible Euler equations is being discretized and relaxed as such. This allowed to construct a highly efficient multigrid solver (see [1]).

What can be observed clearly in the subsonic case is that the fluctuation of the pressure equation (being a part of artificial diffusion of the discretized momentum equations) contributes to the change of the velocities (divergence update) according to exactly the same pattern as the residual of the continuity equation in the schemes for discretizing the equations of incompressible flow.

Thus, the scheme presented in this work establishes a link between some standard techniques used for solving equations of the incompressible flow and the class of upwind schemes commonly used for compressible flow computations.

Acknowledgments. The author would like to express his gratitude to Marsha Berger, Jonathan Goodman and Peter Lax for numerous stimulating discussions and for making his stay at the Courant Institute such an enchanting experience.

The author is also grateful to Philip Roe, Ken Powell and Bram van Leer for their constant interest and support in the course of this work.
