1) Abstract

High temperature superconductors are still under development for various applications. As far as conductors for magnets are concerned, the development has just been started. Small coils wound by silver sheathed Bi-2212 and Bi-2223 oxide conductors have been reported by a few authors.

Essential properties of high T$_c$ superconductors like pinning force, coherent length, intergrain coupling, weak link, thermal property, AC loss and mechanical strength are still not sufficiently understandable.

In this talk, a review is given with comparison between the present achievement and the final requirement for high T$_c$ superconductors, which could be particularly used in accelerator magnets.

Discussions on how to develop high T$_c$ superconductors for accelerator magnets are included with key parameters of essential properties.

A proposal is also given how to make a prototype accelerator magnet with high T$_c$ superconductors with prospect for future development.

2) Introduction

Since the discovery of superconductivity by K. Onnes in 1911, the record of critical temperature (T$_c$) had been updated slowly by the middle of 1980s. The speed of updating the record of T$_c$ was remarkably increased after the discovery of the oxide superconductors in 1986, as shown in Figure 1. The highest record of T$_c$ is approximately 134K for Hg-Ba-Ca-Cu-O$^{1)}$.

The oxide superconductors which have high critical temperatures are generally called high T$_c$ superconductors. In recent years, enormous amounts of research concentrated on high T$_c$ superconductors all over the world.

In addition to basic studies on superconductivity, various applications to films, tapes and wires have also been intensively studied. However, the high T$_c$ materials are not well-understood in the viewpoints of solid-state physics and industrial production.

Characteristics of metallic and inter-metallic superconductors, which have low T$_c$, are also improved continuously. Copper stabilized Nb-Ti wires have become applicable for the magnets in the region of 10T with superfluid helium cooling. A15 compound as Nb$_3$Sn copper stabilized superconductor has become also applicable for magnets of 12T at 4.5K with liquid helium cooling.

The superconducting cables commonly used for accelerator dipole and quadrupole magnets in the range of several teslas are Nb-Ti Copper cables and practically operated at 4.5K with liquid helium cooling. Some magnets are wound with copper stabilized Nb$_3$Sn wires for actual operation around 12T at 4.5K. Nevertheless, it is difficult to use these wires and cables in the operation beyond 15T.

Recently, it was found that some oxide superconductors are applicable up to 30T at 4.2K$^{2)}$ as shown in Figure 2. This is quite attractive in application to generate a very high magnetic field.
Figure 3 shows the $T_c$ of the metallic and the oxide superconductors. A15 intermetallic compound superconductor shows intermediate values between those of metallic and oxide superconductors in $T_c$ and $H_c$.

3) Present status of high $T_c$ superconducting wires and cables

There are three types of high $T_c$ superconducting wires and cables, e.g., Bi-, Y- and Tl-based materials. Among these materials, Bi-based ones are considered as a main stream of development. Specially, Bi-2223 and Bi-2212 are studied by many researchers.

Bi-based silver sheathed Bi-2223 and Bi-2212 have been remarkably developed as the high $T_c$ wires and cables for magnets. G. J. Yurek has manufactured multi-core, tape-shaped wires using a combination of the metallic precursor method, and the silver-sheath method and the technique to produce about 300m long wires has been established. The wire $J_c$ is reported to be around 50A/mm$^2$ at 20K in 5T for 3m long wires, and $J_c=37A$ and 24A at 77K in 0T for 30m and 300m long cables, respectively.

P. Haldar et al., reported the results of the test of short samples at 4.2K, 27K and 77K under magnetic fields up to 20T. Quite recently, T. Hikata et al., reported the result of 1km-class silver-sheathed Bi-based superconducting wires. They made monofilamentary and 61-multifilamentary wires. A $J_c$ of 40A/mm$^2$ was achieved for 1,080m long wire. An anisotropy for the direction of external magnetic fields was found in $J_c$. They measured the parameter $(J_c \times \text{length})$. The maximum value was $(J_c \times \text{length})=9.91 \times 10^{10} \text{[A/m]}$ for 623m long wire. Figure 4 shows the 1080m long high $T_c$ tape wound in a coil.

Pancake coils wound with high $T_c$ wires and cables were studied by S. Meguro. He studied the temperature dependence of $J_c$ of Bi-2212 wire in magnetic fields and showed the possibility to operate the Jelly Rolled Bi-2212 silver sheathed superconductor below 20K.

Among high $T_c$ superconductors available at present, it seems, only Bi-based silver sheathed conductors have suitable characteristics for accelerator magnet application. Bi-2212 silver sheathed tapes were significantly improved in $J_c$ with the formation of the high c-axis orientation of laminated grains and reached $J_c = 350A/mm^2$ at 77K with zero external magnetic field. However, $J_c$ was lowered down to $\approx 4A/mm^2$ at the same temperature with an external field of 1T. The large magnetic field dependence is not suitable for accelerator magnet application at 77K. Further study is necessary to find the method to satisfy both requirements of high $J_c$ and $I_c$.

On the other hand, this highly c-axis oriented Bi-2212 high $T_c$ superconducting tape could survive since it shows high $J_c \approx 20A/mm^2$ with the external magnetic field as high as 30T, if it is cooled down to 4.2K.

The $J_c$ of high $T_c$ superconductor around several tesla is still much lower than that of metallic superconductors which are presently used as accelerator magnets.

4) Requirements for superconducting wires and cables of accelerator magnets

The advantage of using high $T_c$ materials for accelerator magnets is that the refrigeration system for high $T_c$ magnets is much simpler than that for conventional metallic superconducting magnets. Quench protection from the heat load due to beam radiation is also expected to be easier.
The requirements for accelerator magnets are complicated since they must be determined after a delicate adjustment of various parameters which are not always compatible with one another. We discuss an overview of common requirements for 10T-class superconducting magnets which are desirable for a multi-TeV accelerator.

The beam size of the accelerator is preferred to be as small as reasonably achievable by optimizing the beam optics and improving a beam cooling technique, since the costs have risen remarkably for large scale magnets. A small magnet for a high field requires a high current density. The current density of 400A/mm² in the windings is a reasonable goal, which requires the current density of more than 1000A/mm² in the wires. This implies that the electric insulation must endure 100-150MPa at low temperatures. The choice of insulation materials and the manufacturing technique must be improved to achieve these conditions.

5) Proposed high T

C superconducting accelerator magnet cables

As mentioned in the previous section, requirements for superconducting wires and cables of accelerator magnets are remarkably severe. Further improvement is necessary for the production of high T

C superconductors for this application.

A possible solution to apply high T

C superconducting wires for accelerator magnets is to make a so-called superferric magnet as shown in Figure 5. In this configuration, the superconducting coil is cooled down together with the magnetic iron and enables us to assemble accelerator magnets below 2T. However, wires and cables are required to have much more mechanical strength and much better performance for the application to accelerator magnets which can be operated in the magnetic field larger than 2T, e.g. 5 to 10T.

One possible way to develop such wires and cables with high T

C superconductors is to combine the longitudinal in-situ and radial Jelly Rolled structures of the wire strands. The longitudinal in-situ structure within the coherent length of polycrystals in metallic wire will improve the \( J_c \) along the wire length and the Jelly Roll will also improve the \( J_c \) deterioration with external magnetic field. We believe that such a structure of high T

C superconducting wires should be created and tested for the future application to accelerator magnet.

6) Conclusions

Superconducting accelerator magnets require high T

C cables which show a high \( J_c \) and \( I_c \) with a strong magnetic field.

A proposed solution for these requirements is to develop the Jelly-Rolled Bi-2212 silver sheathed round wires. The multi-layer and round shape cross-sectional structure could be another solution for high \( J_c \) and \( I_c \) requirements. The \( J_c \) characteristics of this type of wires will be heavily deteriorated above 20K, therefore it is suitable for magnet operation at temperatures below 20K.

Another solution to develop accelerator magnet wire and cable would be found in a further study of the in-situ structure in high T

C polycrystal superconductors by adjusting their coherent length in appropriate metallic sheaths and/or stabilizers.

From the viewpoint of accelerator magnet application, we expect the development of high T

C superconducting wire with high \( J_c, I_c \) and lengths over 1 km in near future.
It is still very hard to see how high-T_c superconducting wires could be operated with high-J_c and high-I_c at the temperature around 70K. Further study of high T_c superconductors are strongly desired.

7) Acknowledgments

The author is grateful to Drs. K. Sato of SEI and S. Meguro of FEC for their kind suggestions. He is also grateful to staff members of Cryogenics Center of KEK for the preparation of this paper.
