Abstract

A combined finite element method (FEM) and method of moments (MoM) technique is presented to analyze the radiation characteristics of a cavity-fed aperture in three dimensions. Generalized feed modeling has been done using the modal expansion of fields in the feed structure. Numerical results for some feeding structures such as a rectangular waveguide, circular waveguide, and coaxial line are presented. The method also uses the geometrical theory of diffraction (GTD) to predict the effect of a finite ground plane on radiation characteristics. Input admittance calculations for open radiating structures such as a rectangular waveguide, a circular waveguide, and a coaxial line are presented. Numerical data for a coaxial-fed cavity with finite ground plane are verified with experimental data.

1. Introduction

Cavity-backed aperture antennas are very popular in aerospace applications because of their conformal nature. The cavities can also have various types of microstrip antennas residing in them. Hybrid techniques have recently become attractive for the numerical analysis of these types of problems. The combined finite element method and method of moments (FEM and MoM) techniques, in particular, have been used to analyze various cavity-backed antenna systems (ref. 1).

The FEM has a relatively simple formulation and is attractive for complex penetrable structures. Also, it results in sparse, banded matrices that can be effectively stored and solved. However, the FEM when used alone does not incorporate the Sommerfield radiation condition and hence requires discretization to extend far from the source region so that the radiation condition can be imposed. Recent efforts have concentrated on the use of absorbing boundary conditions to reduce the discretization region (ref. 2). Unfortunately, the accuracy of these approximate boundary conditions depends on specific problem geometry, leading to results of unpredictable accuracy.

The method of moments (MoM), on the other hand, incorporates the Sommerfield radiation condition through the use of the appropriate Green’s function. As a result, the domain discretization can be kept to a minimum. However, this method has the disadvantage of being difficult to implement for complex penetrable structures. This method also results in full matrices whose treatment requires excessive storage, limiting its application to small-scale devices.

To eliminate the disadvantages of both methods, several authors have proposed a combined approach (refs. 3 and 4) for radiation and scattering problems. For a comprehensive list of references on hybrid FEM/MoM techniques, see reference 5, chapter 9.

The modeling of the coaxial feed in reference 1 is accomplished by replacing the feed probe by a constant filament of current with a delta-gap generator. The feed modeling in reference 1 is expected to give good results for shallow cavities, but deep cavities require rigorous feed modeling. In this paper a combined FEM/MoM approach is used to predict characteristics of cavity-backed antennas (fig. 1). Various feed lines such as a rectangular waveguide, a circular waveguide, and a coaxial line are considered. Using the modal expansions of fields in the feed, the input admittance of cavity-backed antennas is calculated accurately.

In most antenna-pattern measurements, the infinite ground plane is simulated by a relatively large finite ground plane. Although this simulation does not appreciably affect the input admittance measurements, diffractions from the edges of the ground plane modify the radiation pattern considerably. In the past, the geometrical theory of diffraction (GTD) was successfully applied to predict the changes in the radiation pattern of the aperture antennas caused by a finite ground plane (ref. 6). The technique
The body of this paper is organized in the following manner. Section 2 presents the theory for cavity-backed apertures in infinite ground planes. Section 3 compares the numerical results calculated using the present analysis with the available results in the literature. The input admittance calculations for an open rectangular waveguide, a circular waveguide, and a coaxial line are presented and compared with the results available in the literature. To verify the validity of the GTD technique used in combination with the FEM/MoM technique, the radiation patterns of a coaxial cavity with finite ground plane are calculated and compared with experimental results measured at the Langley Low-Frequency Antenna Test Facility. Numerical data for input return loss of such a coaxial cavity are also computed and compared with experimental data. Section 4 presents concluding remarks. For completeness, an appendix includes expressions for modal expansions of electric fields of input-feed-line structures.

Symbols

A

FEM/MoM matrix

$A_{pq}, B_{pq}$

amplitude of modal vectors in feed

$a, b$

length and width of rectangular waveguide, respectively

$a_m$

reflection coefficients for TEM/TE modes

$b$

excitation matrix

$b_m$

reflection coefficients for TM modes

$D_s, D_h$

diffraction coefficients

$ds$

surface integral

$dv$

volume integral

$E$

time-harmonic electric field

$E_{inc}$

incident electric field

$E_{inp}$

electric field coming from transmission line input

$e$

unknown coefficient matrix

$e_i$

unknown coefficients as defined in equation (8)

$e_{inc}$

modal vector function for incident electric field in feed structure

$e^{TE}_m$

TEM/TE modes in feed line

$e^{TM}_m$

TM modes in feed line

$F$

electric vector potential

$H$

time-harmonic magnetic field

$H_{ap}$

magnetic field at aperture

$H^d$

total diffracted magnetic field

$H^d_A$

diffracted magnetic field from point A

$H^d_B$

diffracted magnetic field from point B

$H^d_C$

diffracted magnetic field from point C
\( \mathbf{H}_D^d \) diffracted magnetic field from point \( D \)

\( \mathbf{H}_{\text{ff}} \) far field of magnetic field

\( \mathbf{H}_{\text{ff}}^t \) total magnetic far field after adding diffracted field

\( \mathbf{H}_{\text{inp}} \) magnetic field at input surface

\( \mathbf{H}_{\theta\text{ff}} \) magnetic far field, \( \theta \)-component

\( \mathbf{H}_{\phi\text{ff}} \) magnetic far field, \( \phi \)-component

\( \mathbf{H}_{\theta,A}^d \) diffracted magnetic field from point \( A \), \( \theta \)-component

\( \mathbf{H}_{\phi,A}^d \) diffracted magnetic field from point \( A \), \( \phi \)-component

\( \mathbf{H}_{\theta,B}^d \) diffracted magnetic field from point \( B \), \( \theta \)-component

\( \mathbf{H}_{\phi,B}^d \) diffracted magnetic field from point \( B \), \( \phi \)-component

\( J_1 ( ) \) Bessel function of first kind (first order)

\( J_n ( ) \) Bessel function of first kind (\( n \)th order)

\( J'_n ( ) \) derivative of \( J_n ( ) \) with respect to its argument

\( j = \sqrt{-1} \)

\( k_o \) free-space wave number, \( \frac{2\pi}{\lambda} \)

\( k_p \) cutoff wave number for TM modes in circular waveguide

\( k'_p \) cutoff wave number for TE modes in circular waveguide

\( L \) distance between radiating aperture (in \( z = 0 \) plane) and feed-line input surface (in \( z = -L \) plane)

\( L_i \) length of edge of tetrahedral element

\( \mathbf{M} \) magnetic current

\( n \) wedge factor

\( \hat{n} \) unit normal

\( p, q \) mode indices for feed

\( \mathbf{r} \) position vector from origin to field point

\( \mathbf{r}' \) position vector from origin to source point

\( r_c \) radius of circular waveguide

\( r_1, r_2 \) inner and outer radius of coaxial line, respectively

\( r, \theta, \phi \) spherical coordinates

\( S \) surface area

\( S_{ap} \) surface area of aperture (fig. 1)

\( S_{\text{inp}} \) surface area of input plane (fig. 1)

\( \mathbf{T} \) vector testing function for volume elements

\( \mathbf{T}_s \) vector testing function for surface elements
TE  transverse electric
TE\textsubscript{10}  dominant mode in rectangular waveguide
TE\textsubscript{11}  dominant mode in circular waveguide
TEM  transverse electric and magnetic
TM  transverse magnetic
V  volume
\( \mathbf{W}_i \)  vector basis functions for tetrahedral elements, \( i = 1, 2, \ldots, 6 \)
\( \mathbf{W}_j \)  vector basis functions for tetrahedral elements, \( j = 1, 2, \ldots, 6 \)
\( W_1, W_2 \)  length and width of finite ground plane, respectively (fig. 1)
\( X, Y, Z \)  rectangular coordinate axes (fig. 1)
\( \mathbf{x}, \mathbf{y}, \mathbf{z} \)  unit vector along \( X-, Y-, \) and \( Z-\)axis, respectively (fig. 1)
\( Y_{in} \)  input admittance of feed line
\( Y_o \)  characteristic admittance of feed transmission line
\( \alpha_m, \alpha_n \)  simplex coordinates associated with nodes \( m \) and \( n \) in tetrahedral element
\( \beta'_o \)  angle between edge of diffraction and ray of incidence on edge
\( \Gamma \)  reflection coefficient as defined in equation (27)
\( \gamma_{inc} \)  propagation constant of incident field in feed
\( \gamma_m \)  propagation constant of feed line
\( \varepsilon_{op}, \varepsilon_{oq} \)  Neumann’s number
\( \varepsilon_r \)  relative permittivity
\( \eta_o \)  intrinsic impedance of free space
\( \hat{\theta} \)  unit vector along \( \theta-\)direction
\( \lambda \)  free-space wavelength
\( \mu_o \)  free-space permeability
\( \mu_r \)  relative permeability
\( \xi_1 \)  angle between ground plane and diffracted ray from point \( A \)
\( \xi_2 \)  angle between ground plane and diffracted ray from point \( B \)
\( \rho_{cA} \)  distance between center of aperture and diffraction point \( A \)
\( \rho_{cB} \)  distance between center of aperture and diffraction point \( B \)
\( \rho_{cC} \)  distance between center of aperture and diffraction point \( C \)
\( \rho_{cD} \)  distance between center of aperture and diffraction point \( D \)
\( \rho, \phi, z \)  cylindrical coordinates
\( \hat{\rho}, \hat{\phi}, \hat{z} \)  unit vector along \( \rho-, \phi-, \) and \( z-\)direction, respectively
\( \hat{\phi} \)  unit vector along \( \phi-\)direction
\( \chi_{pq} \)  \( p \text{th zero (} p = 1, 2, 3\ldots\text{)} \) of \( J_n (\) )
\( \chi_{pq} \)  

\( \psi_o \)  

\( \omega \)  

\( \Delta \)  

\( \nabla \)  

2. Theory

Figure 1 shows the geometry of the problem to be analyzed. For a linear, isotropic, and source-free region the electric field satisfies the vector wave equation:

\[
\nabla \times \left( \frac{1}{\mu_r} \nabla \times \mathbf{E} \right) - \kappa_o^2 \varepsilon_r \mathbf{E} = 0
\]

(1)

where \( \mu_r \) and \( \varepsilon_r \) are the relative permeability and relative permittivity of the medium in the cavity. The current formulation can be easily modified to incorporate anisotropic materials by using proper tensor quantities for \( \mu_r \) and \( \varepsilon_r \) (ref. 7). The time variation \( \exp (j \omega t) \) is assumed and suppressed throughout this paper.

To facilitate the suitable solution of the partial differential equation in equation (1) with the FEM, equation (1) is multiplied by a vector testing function \( \mathbf{T} \), and the result is integrated over the volume of the cavity. By applying suitable vector identities, we can write equation (1) in its weak form (ref. 8) as

\[
\int \int \int_{V} \frac{1}{\mu_r} (\nabla \times \mathbf{T}) \cdot (\nabla \times \mathbf{E}) dv - \kappa_o^2 \varepsilon_r \int \int \int_{V} \mathbf{T} \cdot \mathbf{E} dv = \int \int \int_{V} \nabla \cdot \left( \frac{1}{\mu_r} \nabla \times \mathbf{E} \right) dv
\]

(2)

Applying the divergence theorem to the integral on the right-hand side of equation (2) and using Maxwell’s equation \( \nabla \times \mathbf{E} = -j \omega \mu_o \mu_r \mathbf{H} \), where \( \mu_o \) is the permeability of free space and \( \omega \) is the angular frequency, we can write equation (2) as

\[
\int \int \int_{V} \frac{1}{\mu_r} (\nabla \times \mathbf{T}) \cdot (\nabla \times \mathbf{E}) dv - \kappa_o^2 \varepsilon_r \int \int \int_{V} \mathbf{T} \cdot \mathbf{E} dv = j \omega \mu_o \int_{S} (\mathbf{T} \times \hat{n}) \cdot \mathbf{H} ds
\]

(3)

where \( \hat{n} \) is the outward unit normal to the surface and \( \mathbf{H} \) is the magnetic field at the surface. Because the tangential electric field is zero on the perfect-electric-conducting (PEC) walls of the cavity, the surface integral in equation (3) is nonzero only over the aperture opening in the infinite ground plane and the input aperture. Hence, we can write equation (3) as

\[
\int \int \int_{V} \frac{1}{\mu_r} (\nabla \times \mathbf{T}) \cdot (\nabla \times \mathbf{E}) dv - \kappa_o^2 \varepsilon_r \int \int \int_{V} \mathbf{T} \cdot \mathbf{E} dv - j \omega \mu_o \int_{S_{ap}} (\mathbf{T} \times \hat{n}) \cdot \mathbf{H}_{ap} ds
\]

\[
= j \omega \mu_o \int_{S_{inp}} (\mathbf{T} \times \hat{n}) \cdot \mathbf{H}_{inp} ds
\]

(4)

where \( S_{ap} \) is the aperture surface and \( S_{inp} \) is the input surface (see fig. 1), \( \mathbf{H}_{ap} \) is the magnetic field at the aperture, and \( \mathbf{H}_{inp} \) is the magnetic field at the input surface.

At this point, the problem can be divided into three parts, the first part involving the discretization and evaluation of volume integrals on the left-hand side of equation (4) and the second part involving...
the discretization and evaluation of the surface integral over \( S_{ap} \). The third part involves the surface integral over the input aperture. These three parts are given explicitly as

\[
I_v = \int \int \frac{1}{\mu_r} (\nabla \times T) \cdot (\nabla \times E) \, dv - k_o^2 \varepsilon_r \int \int T \cdot E \, dv \tag{5}
\]

\[
I_{ap} = -j \omega \mu_o \int_{S_{ap}} (T \times \hat{n}) \cdot H_{ap} \, ds \tag{6}
\]

\[
I_{inp} = j \omega \mu_o \int_{S_{inp}} (T \times \hat{n}) \cdot H_{inp} \, ds \tag{7}
\]

### 2.1. FEM Formulation

To discretize the volume integrals in equation (5), the volume of the cavity is subdivided into small-volume tetrahedral elements. The electric field is expressed in terms of the edge vector basis functions (ref. 5), which enforce the divergenceless condition of the electric field implicitly:

\[
E = \sum_{i=1}^{6} e_i W_i \tag{8}
\]

where \( e_i \) are the unknown coefficients associated with each edge of the tetrahedral element and

\[
W_i = L_i (\alpha_m \nabla \alpha_n - \alpha_n \nabla \alpha_m) \tag{9}
\]

where \( m \) and \( n \) are the nodes connected to form edge \( i \), \( L_i \) is the length of the \( i \)th edge, and \( \alpha_m \) and \( \alpha_n \) are the simplex coordinates associated with nodes \( m \) and \( n \) (ref. 8).

The testing function \( T \) is taken to be the same set of basis functions as that given in equation (8); that is,

\[
T = W_j \quad (j = 1, 2, ..., 6) \tag{10}
\]

Substituting equations (8) and (10) into equation (5) and integrating over the volume of each element yields

\[
I_{ev} = \frac{1}{\mu_r} \sum_{i=1}^{6} \int \int (\nabla \times W_i) \cdot (\nabla \times W_j) e_i e_j \, dv - k_o^2 \varepsilon_r \int \int (W_i \cdot W_j) e_i e_j \, dv \quad (j = 1, 2, ..., 6) \tag{11}
\]

where \( \bigtriangleup \) indicates the integration over the volume of a tetrahedral element and \( I_{ev} \) represents the integral \( I_v \) over a single element volume.

The evaluation of these integrals over a tetrahedral element is given in reference 9. These element matrices are assembled over all the elements in the cavity volume to form a symmetric, sparse matrix of FEM.

### 2.2. MoM Formulation

The discretization of cavity volume into tetrahedral elements automatically results in the discretization of the aperture into triangular elements at the \( z = 0 \) plane. In accordance with the equivalence principle (ref. 10), the fields in the two regions can be decoupled by closing the aperture with a perfect electric conductor and introducing the equivalent magnetic current

\[
M = E \times z \quad (z = 0) \tag{12}
\]
over the extent of the aperture. Hence, from equation (8), the magnetic current over a triangular element can be expressed in terms of the unknown coefficients associated with the tetrahedral elements as

\[ M = \sum_{i=1}^{3} e_i (W_i \times z)|_{z=0} \]  

(13)

Similarly, the testing functions can be modified as

\[ T_s = T \times z = W_j \times z \]  

\[ (j = 1, 2, 3) \]  

(14)

The magnetic field caused by the magnetic current given in equation (13) above the infinite ground plane is given by

\[ H_{ap} = \frac{1}{j \omega \mu_o} (\nabla \times \nabla \times F) \]  

(15)

where the electric vector potential \( F \) (making use of the image theory) is given by

\[ F = \frac{1}{2\pi} \iint_{S_{ap}} M(x', y') \frac{\exp(-jk_o |r - r'|)}{|r - r'|} dx' dy' \]  

(16)

where \( r \) is the field point and \( r' \) is the source point.

Using the appropriate vector identities, we can rewrite the equation for the radiated magnetic field in equation (15) as (ref. 10)

\[ H_{ap} = \frac{1}{j \omega \mu_o} \left[ k_o^2 F + \nabla (\nabla \cdot F) \right] \]  

(17)

Substituting equation (17) into equation (6) and using standard surface vector calculus formulas (ref. 11) yields

\[ I_{ap} = -k_o^2 \iint_{S_{ap}} T_s \cdot F ds + \iint_{S_{ap}} (\nabla \cdot T_s)(\nabla \cdot F) ds \]  

(18)

The integrals in the above equation are evaluated over all the triangles on the aperture surface following the procedure outlined in Rao et al. (ref. 11). When calculating the mutual term over the triangles, a 13-point Gaussian quadrature formula developed for triangles (ref. 12) is used. Closed-form expressions given by Wilton et al. (ref. 13) are used to evaluate the self term of these integrals. The dense matrix thus formed is assembled over all the triangles and combined with the FEM matrix using a global numbering system.

### 2.3. Input Integral

For any transmission line input, the electric field can be formulated as the sum of the incident and reflected fields.

\[ E_{inp} = E_{inc} + \sum_m \left[ a_m e_m^{TE}(x, y) + b_m e_m^{TM}(x, y) \right] \exp(\gamma_m z) \]  

(19)

\[ E_{inc} = e_{inc} \exp(-\gamma_{inc} z) \]  

(20)
where $E_{\text{inc}}$ is the incident electric field with unit amplitude, $e_m^{TE}$ and $e_m^{TM}$ represent the TEM/TE\(^1\) and the TM mode, respectively, $a_m$ and $b_m$ are the reflection coefficients for the TEM/TE and the TM mode, respectively, and $\gamma_m$ is the propagation constant. With the orthogonality properties of the waveguide modes (ref. 10), the reflection coefficients are

$$a_m = \exp(-\gamma_m z) \int_{S_{\text{inp}}} e_m^{TE} \cdot (E - E_{\text{inc}}) \, dx \, dy$$

$$b_m = \exp(-\gamma_m z) \int_{S_{\text{inp}}} e_m^{TM} \cdot (E - E_{\text{inc}}) \, dx \, dy$$

The magnetic field at the waveguide input is given by

$$H_{\text{inp}} = -\frac{1}{j \omega \mu_o} \left( \frac{1}{\mu_r} \nabla \times E_{\text{inp}} \right)$$

Substituting $a_m$ and $b_m$ in equation (23) and then using equation (23) in equation (7) and integrating over the feed-line cross section at $z = -L$, we can write equation (7) as

$$I_{\text{inp}} = 2 \gamma_{\text{inc}} \exp(\gamma_{\text{inc}} L) \int_{S_{\text{inp}}} T \cdot e_{\text{inc}} \, dx \, dy$$

$$- \sum_m \gamma_m \left( \int_{S_{\text{inp}}} T \cdot e_m^{TE} \, dx \, dy \right) \left( \int_{S_{\text{inp}}} E \cdot e_m^{TE} \, dx \, dy \right)$$

$$+ \sum_m \frac{k_o^2}{\gamma_m} \left( \int_{S_{\text{inp}}} T \cdot e_m^{TM} \, dx \, dy \right) \left( \int_{S_{\text{inp}}} E \cdot e_m^{TM} \, dx \, dy \right)$$

2.4. FEM/MoM Matrix Equation

Combining all the integrals given in equations (5)–(7), we can write the system equation for this problem as

$$\int \int \int \frac{1}{\mu_r} (\nabla \times T) \cdot (\nabla \times E) \, dv - k_o^2 e_r \int \int T \cdot E \, dv - j \omega \mu_o \int (T \times \hat{n}) \cdot H_{\text{ap}} \, ds$$

$$+ \sum_m \gamma_m \left( \int_{S_{\text{inp}}} T \cdot e_m^{TE} \, dx \, dy \right) \left( \int_{S_{\text{inp}}} E \cdot e_m^{TE} \, dx \, dy \right)$$

$$- \sum_m \frac{k_o^2}{\gamma_m} \left( \int_{S_{\text{inp}}} T \cdot e_m^{TM} \, dx \, dy \right) \left( \int_{S_{\text{inp}}} E \cdot e_m^{TM} \, dx \, dy \right)$$

$$= 2 \gamma_{\text{inc}} \exp(\gamma_{\text{inc}} L) \int_{S_{\text{inp}}} T \cdot e_{\text{inc}} \, dx \, dy$$

\(^1\)Because the analysis is assumed to be valid for a generalized feed line, both TEM and TE modes are represented. They need only be used when applicable.
Substituting the expansion functions for $E$ and $T$ converts this equation into a set of linear equations to solve for the unknown $e_i$ given in equation (8). The linear equation system to be solved is written in matrix form as

$$Ae = b$$  \hspace{1cm} (26)

where $A$ is a partly sparse (from the FEM) and partly dense (from the MoM and the modal expansion method) matrix, $b$ is the excitation vector, and $e$ is the unknown vector to be solved. The biconjugate gradient algorithm is used with diagonal preconditioning (ref. 14) to solve equation (26) efficiently. This algorithm also makes use of the symmetry of the matrix to store the matrix effectively.

2.5. Reflection Coefficient and Input Admittance

Solving equation (25) and using equations (21) and (22), we can obtain the reflection coefficients of any waveguide mode:

$$\Gamma = a_m \text{ or } \Gamma = b_m$$  \hspace{1cm} (27)

The input admittance is then calculated as

$$Y_{in} = \frac{1 - \Gamma}{1 + \Gamma} Y_o$$  \hspace{1cm} (28)

where $Y_o$ is the characteristic admittance of the feed transmission line.

2.6. Far Field With Infinite Ground Plane

Once the electric field in the aperture is known, using equation (13) for the magnetic current, the magnetic far field with infinite ground plane can be evaluated directly from the following equation:

$$\mathbf{H}_{ff}(r, \theta, \phi)|_{r \to \infty} = -\frac{jk_o \exp(-jk_o r)}{2\pi r} \int \int_{S_{ap}} \left( \hat{\theta} \hat{\phi} + \hat{\phi} \hat{\theta} \right) \cdot \mathbf{M}(x, y) \exp[jk_o \sin \theta (x \cos \phi + y \sin \phi)] dx \, dy$$  \hspace{1cm} (29)

2.7. Application of GTD for Finite Ground Planes

The infinite-ground-plane solution described in the preceding sections yields the field radiated in the forward direction. This solution is obtained with equation (29). The effect of the finite ground plane is incorporated by using the compact edge diffraction coefficients (ref. 15) and following the procedure described in reference 6. The radiation fields are supplemented by the additional field contributions arising from the diffraction by the edges of the finite ground plane. The diffraction field supplements the field in the forward region, whereas it accounts totally for the field in the shadow region (behind the finite ground plane) where the infinite-ground-plane solution gives a zero field.

The geometry of the finite rectangular ground plane is illustrated in figure 1. The midpoints on the two edges of length $W_2$ are given by $A$ and $B$, respectively. The midpoints on the two edges of length $W_1$ are given by $C$ and $D$, respectively. The diffracted fields from $A$ and $B$ are given by (ref. 6)

$$H'_{\theta, A} = \frac{1}{2} H_{\theta ff}(d, \frac{\pi}{2}, 0) D_s(\rho_{cA}, \xi_1, \psi_o, \beta'_{o, n}) \left[ \frac{\rho_{cA}}{r(r + \rho_{cA})} \right]^{1/2} \exp(-jk_o r) \exp(jk_o d\sin \theta)$$  \hspace{1cm} (30)

$$H'_{\theta, B} = \frac{1}{2} H_{\theta ff}(d, \frac{\pi}{2}, \pi) D_s(\rho_{cB}, \xi_2, \psi_o, \beta'_{o, n}) \left[ \frac{\rho_{cB}}{r(r + \rho_{cA})} \right]^{1/2} \exp(-jk_o r) \exp(-jk_o d\sin \theta)$$  \hspace{1cm} (31)
for \( \phi \) polarization, and

\[
H_{\phi, A}^d = \frac{1}{2} H_{\phi, ff} (d, \frac{\pi}{2}, 0) D_h (\rho_{cA}, \xi_1, \psi_o, \beta_o', n) \left[ \frac{\rho_{cA}}{r(r + \rho_{cA})} \right]^{1/2} \exp(-jk_o r) \exp(jk_o d \sin \theta) \tag{32}
\]

\[
H_{\phi, B}^d = \frac{1}{2} H_{\phi, ff} (d, \frac{\pi}{2}, \pi) D_h (\rho_{cB}, \xi_2, \psi_o, \beta_o', n) \left[ \frac{\rho_{cB}}{r(r + \rho_{cA})} \right]^{1/2} \exp(-jk_o r) \exp(-jk_o d \sin \theta) \tag{33}
\]

for \( \theta \) polarization. In the preceding equations,

\[
\rho_{cA} = \rho_{cB} = d = \frac{W_1}{2} \tag{34}
\]

and

\[
\xi_1 = \frac{\pi}{2} + \theta \quad \text{for } 0 \leq \theta \leq \pi \tag{35}
\]

\[
\xi_2 = \begin{cases} 
\frac{\pi}{2} - \theta & \text{for } 0 \leq \theta \leq \frac{\pi}{2} \\
\frac{5\pi}{2} - \theta & \text{for } \frac{\pi}{2} < \theta \leq \pi 
\end{cases} \tag{36}
\]

where

\( \psi_o \) angle of incidence from aperture (source) toward the point of diffraction (\( A \) or \( B \)) = 0°

\( \beta_o' \) \( \frac{\pi}{2} \) for normal incidence (ref. 15, p. 811)

\( n \) wedge factor (ref. 15, figs. 13–30)

Similarly, the diffracted fields from \( C \) and \( D \) are also calculated by replacing \( \rho_{cC} = \rho_{cD} = d = W_2/2 \). The detailed expressions for diffraction coefficients \( D_s \) and \( D_h \) are given by equation (113) of reference 15. Total diffracted field is given by

\[
H^d = \begin{cases} 
H_A^d + H_B^d & \text{for } \phi = 0° \text{ plane} \\
H_C^d + H_D^d & \text{for } \phi = 90° \text{ plane}
\end{cases} \tag{37}
\]

The diffracted fields for the \( \phi = 180° \) and \( \phi = 270° \) planes can also be calculated in a similar manner. The total radiated far field is given by adding the diffracted field and magnetic far field given in equation (29); that is,

\[
H_{ff}^f = H_{ff}^d + H^d \tag{38}
\]

The preceding analysis can be easily extended to a circular finite ground plane. If the circular ground plane is symmetrically excited, the diffracted rays come to a focus in the forward and the rear axial direction; that is, the axis of symmetry is a caustic of diffracted rays. The GTD field is not valid at the caustic. However, GTD can be used indirectly to calculate the equivalent edge currents (around the rim of the ground plane) that radiate in the caustic direction; these edge currents are integrated around the circular rim to yield the field in the neighborhood of the caustic. The radiated field evaluation is the same as that described in reference 6.
3. Numerical and Experimental Results

To validate the present analysis, various numerical examples are considered. As a simple case, open-ended waveguide structures excited by a dominant mode field and radiating into half space through an infinite ground plane are analyzed. To study the effect of a finite ground plane, this paper considers a coaxially fed cavity that excites a coaxial aperture in a finite ground plane. The numerical data for these cases are compared with earlier published results and the experimental data obtained at NASA Langley Research Center.

3.1. Apertures in Infinite Ground Plane

3.1.1. Rectangular aperture. A rectangular aperture as shown in figure 2(a) with dimensions \( a = 4.755 \) cm, \( b = 2.215 \) cm, and \( L = 1.9 \) cm in an infinite ground plane and excited by a rectangular waveguide loaded with a dielectric plug (\( \varepsilon_r = 3.76 \)) is considered. The dielectric plug is discretized using 1230 tetrahedral elements. The air-dielectric interface inside the waveguide is considered as the input plane. The dominant TE\(_{10}\) mode is considered to be incident at the plane \( z = -L \). The input admittance of this structure is calculated as a function of frequency and plotted in figure 2(b). The numerical results agree very well with the data presented by Swift (ref. 16).

3.1.2. Circular aperture. A circular aperture in an infinite ground plane and excited by a circular waveguide is considered as a second example. The geometry is shown in figure 3(a). The circular waveguide of length \( L = \lambda \) from the aperture is considered as a circular cavity for FEM discretization. The waveguide is discretized at a level of 0.1\( \lambda \). The dominant TE\(_{11}\) mode is considered to be incident at the plane \( z = -L \). The input admittance is computed as a function of the radius of the waveguide and plotted in figure 3(b) along with the numerical data given by Bailey and Swift (ref. 17). The results computed using the present technique and those of reference 17 agree very well.

3.1.3. Coaxial aperture. As a third example, a coaxial aperture excited by a coaxial line is considered. The geometry is shown in figure 4(a). Again the coaxial line of length \( L = \lambda \) from the aperture is considered as a coaxial cavity for FEM discretization. The coaxial line is discretized at a level of 0.1\( \lambda \). Only the dominant TEM mode is considered for both incident and reflected fields in the coaxial feed line because the higher order modes do not seem to contribute to the final result. (See appendix section A.3.) The input admittance is computed as a function of frequency and plotted in figure 4(b). The results are compared with the available data in the literature (ref. 18).

3.2. Apertures in Finite Ground Plane

To verify the validity of the current method when combined with GTD, a coaxial cavity with a finite ground plane is considered. The geometry of the cavity is shown in figure 5. The cavity is fed by a coaxial line with the center conductor extending up to the radiating aperture. The cavity is discretized using 4474 tetrahedral elements, resulting in 4904 unknowns. For experimental verification, the cavity with dimensions as given in figure 5 was fabricated and its input-return loss and radiation patterns as a function of frequency measured. Figure 6 presents the input-return loss computed using the present method, assuming infinite ground plane, along with the experimental results. The finite ground plane in this case does not affect the input-return loss properties.

The far-field patterns for the structure shown in figure 5 were calculated with equation (37) for two frequencies, 5.0 GHz and 9.0 GHz. Figures 7 and 8 show the calculated values along with the experimental data. The good agreement between the calculated results and the experimental data validates the present analysis. Because the radiation pattern of an antenna depends upon the aperture field, it is useful to know the tangential electric field at the aperture of the structure (shown in fig. 5). In figures 9 and 10 the tangential electric field at the aperture is plotted for 5.0 GHz and 9.0 GHz, respectively. As expected, the aperture field deviates from the TEM field distribution as the frequency increases.
4. Conclusions

A combined finite element method/method of moments/geometrical theory of diffraction (FEM/MoM/GTD) technique was presented to analyze radiation from cavity-backed apertures with finite ground planes. Various numerical examples were considered to demonstrate the flexibility and validity of the method. The numerical data obtained using the present method and the data available in the literature agree very well. The successful application of the GTD was demonstrated by calculating the radiation patterns of a coaxial cavity with finite ground plane and comparing the theoretical results with the experimental data. By virtue of the FEM, this combined FEM/MoM/GTD technique is applicable to arbitrarily shaped cavities filled with inhomogeneous and anisotropic materials. With proper modeling, microstrip antenna arrays residing in cavities with finite ground planes can be also analyzed. This technique can also be easily extended to a finite circular ground plane.
Appendix

Modal Expansions of Feed Structures

For completeness, expressions for the modal expansions of electric fields (eq. (19)) at the input plane of feed structures are given below, with the incident field given by equation (20).

A.1 Rectangular Waveguide

The cross section of the input plane of the rectangular waveguide is shown in figure A1. The incident electric field is assumed to be the dominant TE_{10} mode, which is given by

\[
e_{\text{inc}} = -j \frac{2}{\sqrt{ab}} \cos \left( \frac{\pi x}{a} \right)
\]

\[
\gamma_{\text{inc}} = j \sqrt{k_o^2 - \left( \frac{\pi}{a} \right)^2}
\]

The reflected electric fields for TE and TM modes are written with mode \( m = (p, q) \) as (ref. 10)

\[
e_{m}^{TE} = A_{pq} x \left( \frac{p\pi}{a} \right) \cos \left[ \frac{p\pi}{a} \left( x + \frac{a}{2} \right) \right] \sin \left[ \frac{q\pi}{b} \left( y + \frac{b}{2} \right) \right] - A_{pq} y \left( \frac{p\pi}{a} \right) \sin \left[ \frac{p\pi}{a} \left( x + \frac{a}{2} \right) \right] \cos \left[ \frac{q\pi}{b} \left( y + \frac{b}{2} \right) \right]
\]

\[
(p \text{ and } q = 0, 1, 2, \ldots; \text{if } p = 0, q \neq 0; \text{if } q = 0, p \neq 0) \quad (A2)
\]

and

\[
e_{m}^{TM} = x A_{pq} \left( \frac{p\pi}{a} \right) \cos \left[ \frac{p\pi}{a} \left( x + \frac{a}{2} \right) \right] \sin \left[ \frac{q\pi}{b} \left( y + \frac{b}{2} \right) \right]
\]

\[
+y A_{pq} \left( \frac{q\pi}{b} \right) \sin \left[ \frac{p\pi}{a} \left( x + \frac{a}{2} \right) \right] \cos \left[ \frac{q\pi}{b} \left( y + \frac{b}{2} \right) \right]
\]

\[
+z \frac{A_{pq}}{\gamma_m} \left( \frac{p\pi}{a} \right)^2 + \left( \frac{q\pi}{b} \right)^2 \sin \left[ \frac{p\pi}{a} \left( x + \frac{a}{2} \right) \right] \cos \left[ \frac{q\pi}{b} \left( y + \frac{b}{2} \right) \right]
\]

\[
(p = 0, 1, 2, 3, \ldots; q = 0, 1, 2, 3, \ldots) \quad (A3)
\]

where

\[
A_{pq} = \sqrt{\varepsilon_{op} \varepsilon_{oq}} \frac{1}{ab} \sqrt{\left( \frac{p\pi}{a} \right)^2 + \left( \frac{q\pi}{b} \right)^2}
\]

\[
\varepsilon_{op} = \begin{cases} 2 & \text{for } p \neq 0 \\ 1 & \text{for } p = 0 \end{cases}
\]

and

\[
\varepsilon_{oq} = \begin{cases} 2 & \text{for } q \neq 0 \\ 1 & \text{for } q = 0 \end{cases}
\]
A.2 Circular Waveguide

The cross section of the input plane of the circular waveguide is shown in figure A2. The incident electric field is assumed to be the dominant TE$_{11}$ mode, which is given by

\[ e_{\text{inc}} = A_{11} \left\{ \hat{\rho} \left[ -\frac{1}{\rho} J_1(k'_{\rho} \rho) \cos \phi \right] + \hat{\phi} \left[ k'_{\rho} J_1'(k'_{\rho} \rho) \sin \phi \right] \right\} \]  

(A6)

and

\[ \gamma_{\text{inc}} = j \sqrt{k_o^2 - k_{\rho}^2} \]  

(A7)

where \( k'_{\rho} = \frac{\chi'_{11}}{r_c} \) and \( \chi'_{11} \) represents the first zero of the derivative of the Bessel function \( J_1 \).

Equation (A9) defines \( A_{11} \) with \( p = 1 \) and \( q = 1 \). The reflected electric fields for TE and TM modes with \( m = (p, q) \) are given by

\[ e_{m}^{TE} = A_{pq} \left\{ \hat{\rho} \left[ -\frac{q}{p} J_q(k'_{\rho} \rho) \cos (q \phi) \right] + \hat{\phi} \left[ k'_{\rho} J_q'(k'_{\rho} \rho) \sin (q \phi) \right] \right\} \]  

(A8)

\[ e_{m}^{TM} = B_{pq} \left\{ \hat{\rho} \left[ k'_{\rho} J_q'(k'_{\rho} \rho) \sin (q \phi) \right] + \hat{\phi} \left[ \frac{q}{p} J_q(k'_{\rho} \rho) \cos (q \phi) \right] \right\} \]

\[ + z \frac{p_{pq}}{\gamma_m} [(k_o^2 + \gamma_m^2) J_q(k'_{\rho} \rho) \sin (q \phi)] \]  

(A9)

where \( k'_{\rho} = \frac{\chi'_{pq}}{r_c} \) and \( k'_{\rho} = \frac{\chi'_{pq} \cdot \chi'_{pq}}{r_c} \) is the pth zero (\( p = 1, 2, \ldots \)) of the derivative of the Bessel function \( J_q \) of the first kind of order \( q \) (\( q = 0, 1, 2, \ldots \)). \( \chi_{pq} \) is the pth zero (\( p = 1, 2, 3, \ldots \)) of the Bessel function \( J_q \) of the first kind of order \( q \) (\( q = 0, 1, 2, \ldots \)), and

\[ A_{pq} = \frac{\varepsilon_{oq}^{pq}}{\sqrt{\pi (\chi_{pq}^2 - q^2)}} \frac{1}{J_q(\chi_{pq})} \]  

(A10)

\[ B_{pq} = \frac{\varepsilon_{oq}^{pq}}{\pi} \frac{1}{\chi_{pq} J_q'(\chi_{pq})} \]  

(A11)
\[ \gamma_m = \begin{cases} j \sqrt{k_o^2 - \kappa^2} & (k_o > \kappa) \\ \sqrt{\kappa^2 - k_o^2} & (k_o \leq \kappa) \end{cases} \] (A12)

where \( \kappa = k'_\rho \) for TE modes and \( \kappa = k_\rho \) for TM modes.

A.3 Coaxial Line

The cross section of the input plane of the coaxial line is shown in figure A3. The incident electric field is assumed to be the dominant TEM mode and is given by

\[ e_{\text{inc}} = \hat{\rho} \frac{1}{\kappa} \frac{1}{\rho} e^{j k_o} \] (A13)

\[ \gamma_{\text{inc}} = j k_o \] (A14)

In a practical feed-line arrangement, the coaxial line is relatively small in diameter and the amplitudes of the higher order coaxial modes that are excited are small. A reasonable approximation is to assume that only a reflected TEM mode exists in the coaxial line. Hence, in equation (19),

\[ e^{TE}_m = \hat{\rho} \frac{1}{\kappa} \frac{1}{\rho} e^{j k_o} \] (A15)

\[ e^{TM}_m = 0 \] (A16)

\[ \gamma_m = j k_o \] (A17)

A combined finite element method (FEM) and method of moments (MoM) technique is presented to analyze the radiation characteristics of a cavity-fed aperture in three dimensions. Generalized feed modeling has been done using the modal expansion of fields in the feed structure. Numerical results for some feeding structures such as a rectangular waveguide, circular waveguide, and coaxial line are presented. The method also uses the geometrical theory of diffraction (GTD) to predict the effect of a finite ground plane on radiation characteristics. Input admittance calculations for open radiating structures such as a rectangular waveguide, a circular waveguide, and a coaxial line are presented. Numerical data for a coaxial-fed cavity with finite ground plane are verified with experimental data.
