Modeling and Analysis of the DSS-14
Antenna Control System

W. Gawronski and R. Bartos
Communications Ground Systems Section

An improvement of pointing precision of the DSS-14 antenna is planned for the near future. In order to analyze the improvement limits and to design new controllers, a precise model of the antenna and the servo is developed, including a finite element model of the antenna structure and detailed models of the hydraulic drives and electronic parts. The DSS-14 antenna control system has two modes of operation: computer mode and precision mode. The principal goal of this investigation is to develop the model of the computer mode and to evaluate its performance. The DSS-14 antenna computer model consists of the antenna structure and drives in azimuth and elevation. For this model, the position servo loop is derived, and simulations of the closed-loop antenna dynamics are presented. The model is significantly different from that for the 34-m beam-waveguide antennas.

I. Introduction

The DSS-14 antenna control system model consists of the antenna structure, antenna drives in azimuth and elevation, and the position servo loop. Each drive, in turn, consists of gearboxes, hydraulic servo (active and passive valves, hydraulic lines, and hydraulic motors), and electronics boards (amplifiers and filters). The DSS-14 antenna control system model was developed by R. E. Hill [1,2]. In the present development, we obtain a more precise model that allows for accurate simulations of the antenna pointing errors and allows simulation of the intermediate variables, such as torques, currents, wheel rates, truss stresses, etc. We incorporate the finite element structural model with free rotation in azimuth and elevation, in a manner similar to the 34-m antenna models [3-5], that involves cross-coupling effects between azimuth and elevation, wind pressure on the dish, and pointing error model. The hydraulic part involves a recent development in modeling of the hydraulic components by R. Bartos [6-8].

The rate loop model consists of the elevation and azimuth drives and the antenna structure. Each drive consists of three major components: the electronics boards, hydraulic system, and gearbox. A model of each component is derived separately, then put together, forming the drive and rate loop models. Finally, the position loop is closed to obtain the position loop model.

II. Drive Model

A block diagram of the drive model is shown in Fig. 1, where \( N_t \) is the ratio between motor rate and tachometer (pinion) rate; \( r \), rad/s, is the rate input to the drive; \( i \), A, is the hydraulic active valve
solenoid current; \( T_o \) and \( T \), N·m or lb in., are the gearbox and on-axis torques, respectively; and \( \dot{\theta}_{\text{tach}} \) and \( \dot{\theta}_m \), rad/s, are the pinion and motor rates, respectively. The state-space representation of the electronic board, hydraulic system, and gearbox are derived in the following sections.

A. Electronic Board

A schematic diagram for the electronic board is shown in Fig. 2. The inputs are the rate command \( r \), rad/s, and the tachometer rate \( \dot{\theta}_{\text{tach}} \), rad/s. The output is the solenoid valve current \( i \). The scaling factors, \( k_r \) and \( k_t \), convert the inputs into the command voltage, \( v_r \), and tachometer voltage, \( v_t \). The subsystem, \( G_t \), is the tachometer circuit: it transforms the tachometer voltage, \( v_t \), into the voltage, \( v_{to} \). The subsystems with the transfer functions \( G_{r1} \) and \( G_{r2} \) are the rate amplifier circuits: they transform the command voltage, \( v_r \), and the tachometer voltage, \( v_{to} \), into the error voltage, \( v_s \). The subsystem with the transfer function, \( G_s \), is the valve driver amplifier circuit, with the error voltage, \( v_s \), as the input and the valve current, \( i \), as the output.

The following transfer functions of each of the four components are derived in the Appendix. The transfer function \( G_{to} \) for azimuth is

\[
G_{to} = 0.151
\]  

and, for elevation, is

\[
G_{to} = 0.127
\]  

The transfer functions \( G_{r1} \) (from \( v_r \) to \( v_s \)) and \( G_{r2} \) (from \( v_{to} \) to \( v_s \)) are
where \( G_{r1} = 6.20 \ G_o \)
\[
G_{r2} = -4.55 \ G_o
\]

The scaling factors, \( k_r \) and \( k_t \), are \( k_r = 1212.6 \text{ V/rad/s} \) and \( k_t = 2.5 \text{ V/rad/s} \). Thus, the command transfer function from the rate command \( r \) to the solenoid current \( i_s \) is

\[
G_r = k_r G_{r1} G_s = 0.3323 \ G_o
\]

where \( G_o \) is defined in Eq. (4). The tachometer transfer function from the tachometer rate \( \dot{\theta}_{tach} \) to the solenoid current \( i_s \) is

\[
G_t = k_t G_{t0} G_r G_s
\]

The tachometer transfer function from the tachometer rate \( \dot{\theta}_{tach} \) to the solenoid current \( i_s \) is

\[
G_t = \begin{cases} 
-0.7750 \times 10^{-4} G_o & \text{for azimuth} \\
-0.6525 \times 10^{-4} G_o & \text{for elevation} 
\end{cases}
\]

In order to check the correctness of the derivation, note that the ratio \( G_r/G_t \) should be equal to \( N_o \), where \( N_o \) is the tachometer-to-axis ratio (\( N_o = 4287.5 \) for azimuth and \( N_o = 5083.6 \) for elevation). Indeed, from Eqs. (6) and (7), one obtains

\[
\frac{G_r}{G_t} = \begin{cases} 
-4287.7 = N_o & \text{for azimuth} \\
-5092.7 \neq N_o & \text{for elevation} 
\end{cases}
\]

Finally, the state-space representations of the transfer functions \( G_r \) and \( G_t \) (for azimuth and elevation) are easily obtained with the standard Matlab command in the form

\[
\begin{align*}
\dot{x}_b &= A_b x_b + B_{b1} r + B_{b2} \dot{\theta}_{tach} \\
i &= C_b x + D_{b1} r + D_{b2} \dot{\theta}_{tach}
\end{align*}
\]

The plot of the transfer function in azimuth (magnitude and phase) from \( r \) to \( i \) is shown in Fig. 3. The transfer function for elevation is identical. The plots of the transfer functions in azimuth and elevation from \( \dot{\theta}_{tach} \) to \( i \) are shown in Fig. 4. The magnitudes drop in the frequency range from 0.01 to 0.1 Hz due to implementation of the filter \( G_o \).
Fig. 3. Magnitude of the electronic board transfer function from the rate input to the board current.

Fig. 4. Magnitude of the electronic board transfer function from the tachometer rate input to the board current.

B. Hydraulic System

The hydraulic servo system model was presented by R. E. Hill in [1] and [2]. Here we take a different approach, based on the recent investigations of hydraulic components by R. Bartos (see [6–8]). A block diagram of the DSS-14 hydraulic system is shown in Fig. 5. It consists of the hydraulic motor, shorting valve, hydraulic lines A and B, passive servo valves, and active servo valves. It has two inputs, servo valve current \( i \) and motor rate \( \dot{\theta}_m \), and one output, motor torque \( T_o \). The equations for each component are derived separately based on the work of Bartos [6–8]. Basically, these models are nonlinear ones; however, we linearize them in order to model the antenna linear regime of operation.

1. Active Servo Valve. This valve model has the input, \( i \), \( A \), and two outputs, \( q_{av} \)—the flow rate out of port a, \( \text{cm}^3/\text{s} \), or \( \text{in.}^3/\text{s} \), and \( q_{bo} \), the flow rate out of port b, \( \text{cm}^3/\text{s} \), or \( \text{in.}^3/\text{s} \). From [6], one obtains

\[
\dot{q}'_{av} + 2\zeta_o \omega_o \dot{q}_{av} + \omega_o^2 q_{av} = \omega_o^2 k_a i \quad (11a)
\]

\[
q_{bo} = -q_{av} \quad (11b)
\]

where \( \zeta_o = 0.8 \) is the damping ratio, \( \omega_o = 345.6 \text{ rad/s} \) is the valve natural frequency, and \( k_a = 59,200 - 97,300 \text{ cm}^3/\text{s/A} \) (23,300–38300 \text{ in.}^3/\text{s/A}) is the valve gain. The lower value is the Bartos estimate, while the upper value is the Hill estimate [2]. The values of the parameters are listed in Table 1.
Introducing the new variable $q_v = q_{av} - q_{bv}$, one obtains from Eq. (11)'

$$
\dot{q}_v + 2\zeta \omega_0 \dot{q}_v + \omega_0^2 q_v = 2\omega_0^2 k_\alpha i
$$

The differential variable $q_v$ and the other differential variables introduced allow one to further simplify the analysis without loss of accuracy and to get rid of the "parasitic" variables, such as tank pressure, supply pressure, and case pressure.

2. Shorting Valve. The pressures $p_a$ and $p_b$, kPa (lb/in.$^2$), are the inputs to the shorting valve, and the flows $q_{as}$ and $q_{bs}$, cm$^3$/s (in.$^3$/s), are its output (see Fig. 5). The linearized relationship between the inputs and outputs is as follows:

$$
\begin{align*}
q_{as} &= k_a (p_a - p_b) \\
q_{bs} &= -q_{as}
\end{align*}
$$

where $k_a$ is the valve gain, $k_a = 0.0007 - 0.007$ cm$^3$/s/kPa (0.0003–0.003 in.$^3$/s/psi), both in azimuth and elevation.
Introducing new differential variables \( p = p_a - p_b \) and \( q_s = q_{as} - q_{bs} \), one obtains Eq. (13) in the form

\[
q_s = 2k_s p
\]  

(14)

3. Passive Servo Valve. This valve has four inputs: pressures \( p_a \) and \( p_b \), supply pressure \( p_s \), and tank pressure \( p_t \). The last two are supplementary constant inputs that can be removed from the analysis. The valve has two outputs: flows \( q_{ap} \) and \( q_{bp} \). Its linearized input-output relationship is as follows:

\[
q_{ap} = k_{p1}(p_a - p_s) + k_{p2}(p_a - p_t)
\]  

(15a)

\[
q_{bp} = k_{p1}(p_b - p_s) + k_{p2}(p_b - p_t)
\]  

(15b)

where the gains are \( k_{p1} = 0.0055 \text{ cm}^3/\text{kPa} \) (0.00233 in.\(^3\)/psi) and \( k_{p2} = k_{p1} \), the supply pressure is 17,240 kPa (2500 psi), and the tank pressure is 345 kPa (50 psi). These values are identical for azimuth and elevation.

Introducing \( q_p = q_{ap} - q_{bp} \), and recalling that \( p = p_a - p_b \), one obtains Eqs. (15a) and (15b) as follows:

\[
q_p = (k_{p1} + k_{p2})p = 2k_pp
\]  

(16)

where, for simplicity of notation, we denote \( k_p = k_{p1} = k_{p2} \).

4. Hydraulic Motor. The motor is described in [8]. From Fig. 5, it follows that the motor has four inputs and four outputs. The inputs are pressures \( p_a \) and \( p_b \), case pressure \( p_c \), and motor rate \( \theta_m \), rad/s. The outputs are flows \( q_a \) and \( q_b \), leakage to the case \( q_c \), and motor torque \( T_o \), N·m (or lb in.). Following [8], one obtains the flow \( q_a \) from Eq. (59) of [8]:

\[
q_a = q_{a1} + q_{a2} + q_{a3}
\]  

(17)

But, from Eq. (40) of [8],

\[
q_{a1} = D\dot{\theta}_m
\]  

(18)

where \( D = 6.3 \text{ cm}^3/\text{rad} \) (0.3836 in.\(^3\)/rad) is the motor “displacement.” From Eq. (52) of [8], one obtains

\[
q_{a2} = \frac{k_{a2}}{\mu}(p_a - p_c)
\]  

(19)

where \( k_{a2} = 6.35 \times 10^{-5} \) to 18.3 \( \times 10^{-5} \) cm\(^3\) (from 2.5 \( \times 10^{-5} \) to 7.2 \( \times 10^{-5} \) in.\(^3\)) is the leakage constant (assumed to be 10\(^{-4} \) cm\(^3\), or 4 \( \times 10^{-5} \) in.\(^3\)); \( \mu = 2.8 \times 10^{-4} \) to 2.8 \( \times 10^{-3} \) kPa s (from 4 \( \times 10^{-6} \) to 4 \( \times 10^{-5} \) lb s/in.\(^2\)) is the absolute fluid viscosity (assumed to be 10\(^{-4} \) cm\(^3\), or 4 \( \times 10^{-5} \) in.\(^3\)); and \( p_c = 221 \text{ kPa} \) (32 psi). From Eq. (58) of [8], one obtains the leakage from port A to port B, \( q_{a3} \):

\[
q_{a3} = \frac{k_{a3}}{\mu}(p_a - p_b)
\]  

(20)
where \( k_{a3} \) is the constant of proportionality determined through experiments. It is assumed to be equal to \( k_{a2}, k_{a3} = k_{a2} \).

Combining Eqs. (17) through (20), one obtains

\[
q_a = D\dot{\theta}_m + \frac{k_{a2} + k_{a3}}{\mu} p_a - \frac{k_{a3}}{\mu} p_b - \frac{k_{a2}}{\mu} p_c \tag{21}
\]

From [8], Eq. (60), one obtains the flow rate \( q_b \):

\[
q_b = q_{b1} + q_{b2} - q_{a3} \tag{22}
\]

It follows from [8], Eq. (41), that

\[
q_{b1} = -q_{a1} = -D\dot{\theta}_m \tag{23}
\]

and from [8], Eq. (53), that

\[
q_{b2} = \frac{k_{b2}}{\mu} (p_6 - p_c) \tag{24}
\]

Combining Eqs. (22), (23), (24), and (20), one obtains

\[
q_b = -D\dot{\theta} - \frac{k_{a3}}{\mu} p_a + \frac{k_{a3} + k_{b2}}{\mu} p_b - \frac{k_{b2}}{\mu} p_c \tag{25}
\]

The motor torque \( T_o \) is obtained from Eq. (28) of [8] by neglecting Coulomb friction and inertia torques (the latter are included in the gearbox model):

\[
T_o = T_p + T_f \tag{26}
\]

where \( T_p \) is the torque generated by the motor and \( T_f \) is the viscous friction torque. The linearized Eq. (10) of [8] gives the torque generated by the motor:

\[
T_p = D(p_a - p_b) \tag{27}
\]

and from Eq. (24) of [8], one obtains the viscous friction torque:

\[
T_f = -k_v D\mu \dot{\theta} \tag{28}
\]

where \( k_v = 0.0438 \) is a dimensionless viscous friction coefficient. Combining Eqs. (26) through (28), one obtains

\[
T_o = Dp_a - Dp_b - k_v D\mu \dot{\theta} \tag{29}
\]
Define \( q = q_a - q_b \); then from Eqs. (21) and (25), one obtains

\[
\begin{align*}
q &= 2D\dot{\theta}_m + \frac{3k_{a2}}{\mu} p \\
T_o &= Dp - k_v D\mu \dot{\theta}_m
\end{align*}
\]  

(30)

The motor parameters are given in Table 2.

5. **Hydraulic Line.** There are two lines: A and B. A model for line A is developed, and the model for line B is similar (index "a" should be replaced with "b"). Line A has four inputs, flows \( q_a, q_{av}, q_{ap}, \) and \( q_{as} \), and a single output, pressure \( p_a \) (refer to Fig. 5). From [7], one obtains the line-A model as an integrator, with the negative feedback signs as in Fig. 5:

\[
\dot{p}_a = k_{ia} (-q_a + q_{av} - q_{ap} - q_{as})
\]  

(31a)

Similarly, the line-B model is obtained:

\[
\dot{p}_b = k_{ib} (-q_b + q_{bv} - q_{bp} - q_{bs})
\]  

(31b)

As before, defining \( p = p_a - p_b \), one obtains

\[
\dot{p} = k_l (-q + q_o - q_p - q_s)
\]  

(32)

In these equations, the gains are

\[
k_l = \frac{\beta}{v_o}
\]  

(33)

where \( \beta \) is the effective bulk modulus (capacitance of the line), \( \beta = 1.29 \times 10^6 \) kPa (1.87 \times 10^5 psi), and \( v_o \) is the total volume, \( v_o = 27,200 \) cm\(^3\) (1660 in.\(^3\)), so that \( k_l = 47.3 \) kPa/cm\(^3\) (113 psi/in.\(^3\)). The values are collected in Table 3.

6. Hydraulic System Model. The model of the hydraulic system is derived by combining its elements (active servo valve, shorting valve, passive valve, hydraulic lines, and hydraulic motors). By introducing the new differential variables, the block diagram in Fig. 5 is simplified to the one in Fig. 6. A detailed block diagram of the hydraulic system is shown in Fig. 7. Combining Eqs. (12), (14), (16), (32), and (30) (or, alternatively, using the block diagram in Fig. 7), and defining the new state vector $x_h = [x_1, x_2, x_3]^T$, with three states, $x_1 = \dot{q}_m, x_2 = q_v$, and $x_3 = p$, and defining the input current, $i$, motor rate $\dot{\theta}_m$, and the single-output motor torque, $T_o$, one obtains

$$\begin{align*}
\dot{x}_h &= A_h x_h + B_h \dot{\theta}_m + B_hi \\
T_o &= C_h x_h + D_h \dot{\theta}_m + D_hi 
\end{align*}$$

(34a)

where

![Fig. 6. Simplified block diagram of the hydraulic drive.](image)
The plots of the magnitudes of the transfer function in azimuth and elevation from $i$ to $T_o$ are shown in Fig. 8. The plots of the magnitudes of the transfer functions in azimuth and elevation from $\dot{\theta}_m$ to $T_o$ are shown in Fig. 9.

**C. Gearbox Model**

The gearbox model was described in detail in [5], and its block diagram is given in Fig. 10. In this diagram, $T_o$ is the motor torque, $\dot{\theta}_p$ is the antenna angular rate, $\omega_m$ is the motor rate, $T$ is the gearbox
Fig. 8. Magnitude of the hydraulic drive transfer function from the solenoid current to the output torque.

Fig. 9. Magnitude of the hydraulic drive transfer function from the motor rate to the output torque.

Fig. 10. Block diagram of the gearbox.

torque, $J_m$ is the motor inertia, $k_g$ is the gearbox (output) stiffness, and $N$ is the gearbox ratio. This model has two inputs, the motor torque, $T_o$, and the wheel (pinion) angular rate, $\dot{\theta}_p$, and a single output, the gearbox torque, $T$.

The equations for this system are as follows:
Denoting the state variables $x_1 = \omega_m$ and $x_2 = T$, one obtains

$$\dot{J_m}\dot{\omega}_m = T_o - \frac{T}{N} \quad (35a)$$

$$T = k_g \left( \frac{\theta_m}{N} - \theta_p \right) \quad (35b)$$

Defining the state variables $x_1 = \omega_m$ and $x_2 = T$, one obtains

$$\dot{x}_1 = \frac{-x_2}{NJ_m} + \frac{T_o}{J_m} \quad (36a)$$

$$\dot{x}_2 = \frac{k_g x_1}{N} - k_g \dot{\theta}_p \quad (36b)$$

Defining the gearbox state as $x_g = [x_1 \ x_2]^T$, input $T_o$ and $\dot{\theta}_p$, and output $T$ and $\omega_m$, one obtains the gearbox state-space representation $(A_g, B_g, C_g)$:

$$\begin{align*}
\dot{x}_g &= A_g x_g + B_{g1} T_o + B_{g2} \dot{\theta}_p \\
T &= C_{g1} x_g \\
\dot{\theta}_m &= C_{g2} x_g
\end{align*} \quad (37a)$$

where

$$A_g = \begin{bmatrix} 0 & -1 \\ \frac{k_g}{N J_m} & 0 \end{bmatrix}$$

$$B_{g1} = \begin{bmatrix} \frac{1}{J_m} \\ 0 \end{bmatrix}$$

$$B_{g2} = \begin{bmatrix} 0 \\ -k_g \end{bmatrix}$$

$$C_{g1} = [0 \ 1]$$

$$C_{g2} = [1 \ 0] \quad (37b)$$

D. Drive Model

The drive model is obtained by combining the state-space representation of the electronic board, Eq. (10); the hydraulic system, Eq. (34); and the gearbox, Eq. (37), according to the block diagram in Fig. 1. Defining the drive state vector $x_d = [x_b^T, x_h^T, x_g^T]^T$, we obtain the state equations
where
\[ A_d = \begin{bmatrix} A_b & 0 & \frac{B_{b2}C_{g2}}{N_t} \\ B_{hi}C_b & A_h & \frac{B_{hi}D_{be}C_{g2}}{N_t} \\ B_{g1}D_{hi}C_b & B_{g1}C_h & \frac{B_{g1}D_{hi}D_{be}C_{g2}}{N_t} \end{bmatrix} \]

\[ B_{dr} = \begin{bmatrix} \frac{B_{b1}}{N_t} \\ \frac{B_{hi}D_{b1}}{N_t} \\ \frac{B_{g1}D_{hi}D_{b1}}{N_t} \end{bmatrix} \]

\[ B_{dt} = \begin{bmatrix} 0 \\ 0 \\ B_{g2} \end{bmatrix} \]

\[ C_d = [0 \ 0 \ C_{g1}] \]

The plots of the magnitudes of the transfer function in azimuth and elevation from \( r \) to \( T \) are shown in Fig. 11. The plots of the transfer functions in azimuth and elevation from \( \theta_p \) to \( T \) are shown in Fig. 12.

### III. Structure Model

The structural model is derived from the finite element model of the antenna structure with free rotations with respect to the elevation and azimuth axes. The finite element model consists of the diagonal modal mass \( M_m(p \times p) \), diagonal natural frequencies matrix \( \Omega (p \times p) \), diagonal modal damping matrix \( Z(p \times p) \), and modal matrix \( \Phi (m \times p), p \leq m \), which consists of \( p \) eigenvectors \( \phi_i \) (mode shapes), \( i = 1, \ldots, p \):

\[ \Phi = [\phi_1, \phi_2, \ldots, \phi_p] \]

Let the finite element model have \( m \) degrees of freedom, with \( s \) inputs \( u(t) \), where \( u \) is \( s \times 1 \) vector, and with \( r \) outputs \( y(t) \), where \( y \) is \( r \times 1 \) vector. If the input matrix is \( B_o(m \times s) \), the output matrix for displacement is \( C_{ou}(r \times m) \), and the output matrix for rates is \( C_{ov}(r \times m) \), then the input–output relationship is given by the following second-order differential equation:

\[ \ddot{q}_m + 2Z\Omega \dot{q}_m + \Omega^2 q_m = M_m^{-1} \Phi^T B_o u \]

\[ y_m = C_{og} \Phi q_m + C_{ou} \Phi \dot{q}_m \]

Define the state variable \( x \) as follows:
where \( q_m \) and \( \dot{q}_m \) are modal displacements and rates (such that \( q = \Phi q_m \); \( q \) is the actual displacement); then Eq. (40) can be presented as a set of first-order equations:

\[
\begin{align*}
\dot{x}_1 &= x_2 \\
\dot{x}_2 &= -\Omega^2 x_1 - 2Z\Omega x_2 + M_m^{-1} \Phi B_o u_s \\
y_s &= C_{\Phi q} x_1 + C_{\Phi \dot{q}} x_2
\end{align*}
\]  

or in the following form:

\[
\begin{align*}
\dot{x}_s &= A_s x_s + B_s u_s \\
y_s &= C_s x
\end{align*}
\]  

(43a)
where

\[
\begin{align*}
A_s &= \begin{bmatrix} 0 & I \\ -\Omega^2 & -2Z\Omega \end{bmatrix} \\
B_s &= \begin{bmatrix} 0 \\ M^{-1}\Phi^T B_0 \end{bmatrix} \\
C_s &= [C_{a\Phi}, C_{e\Phi}] 
\end{align*}
\]

(43b)

is the sought state-space model in modal coordinates. In our case, \( u_s = [T_a \ T_e] \), where \( T_a \) and \( T_e \) are torques at azimuth wheels and elevation pinions, respectively. The structure output consists of the elevation and azimuth encoder angles and rates, pinion angles, elevation and cross-elevation pointing errors, and other structural variables of interest. Two outputs, \( \dot{\theta}_{pa} \) and \( \dot{\theta}_{pe} \), the pinion rates in azimuth and elevation, are of special interest. Thus, the structural state-space equations are as follows:

\[
\begin{align*}
\dot{x}_s &= A_s x_s + B_s a T_a + B_s e T_e \\
\dot{\theta}_{pa} &= C_{pa} x_s \\
\dot{\theta}_{pe} &= C_{pe} x_s \\
y &= C_s x 
\end{align*}
\]

(44)

The modal data obtained from the finite element model consist of 150 natural frequencies, \( \omega_i \); modes, \( \phi_i \); and modal masses, \( m_i, i = 1, \ldots, 150 \). Additionally, based on the measurements, the modal damping is assumed to be 1 percent, i.e., \( \zeta_i = 0.01 \). Based on this information, the state matrix \( A_s \), as in Eq. (43b), is determined by introducing the matrix of natural frequencies, \( \Omega = diag(\omega_i) \), and modal damping, \( Z = diag(\zeta_i), i = 1, \ldots, 150 \).

The determination of matrices \( B_s \) and \( C_s \) is presented here for the azimuth wheel torque input and the azimuth wheel rate output. For the azimuth wheel torque input, consider the azimuth wheel of radius \( r_a \) and the azimuth rail of radius \( R_a \). Let nodes \( n_1 \) be located at the contact point of the wheel and the rail. The torque applied to the wheel generates the force \( F_a \) at node \( n_1 \). The force is tangential to the azimuth rail. Assuming a rigid pinion, the force \( F_a \) applied to the wheel is

\[
F_a = \frac{T_a}{r_a}
\]

(45)

This force has \( x \) and \( y \) components, \( F_{ax} \) and \( F_{ay} \) [see Fig. 13(a)], such that

\[
\begin{align*}
F_{ax} &= -F_a \cos \alpha_a = -\frac{T_a}{r_a} \cos \alpha_a \\
F_{ay} &= F_a \sin \alpha_a = \frac{T_a}{r_a} \sin \alpha_a 
\end{align*}
\]

(46)
and \( \alpha \) is the angle marked in this figure. Let \( e_x \) and \( e_y \) denote the unit vector (all but one component are zero, and the nonzero component is equal to one), with the unit component at the location of the \( x \) and \( y \) displacement of node \( n_1 \) in the finite element model. The input, \( F \), to the finite element model is \( F = F_{ax}e_x + F_{ay}e_y \). Therefore, \( B_o \) follows from the decomposition of \( F \), such that \( F = B_oT_a \). From Eq. (46), it follows that

\[
B_o = \frac{e_x}{r_a} \cos \alpha + \frac{e_y}{r_a} \sin \alpha
\]  

(47)

Next, from Eq. (43b), it follows that the nonzero (lower) part of \( B \), after introduction of Eq. (47), is

\[
M_m^{-1}\Phi^T B_o = -M_m^{-1}\frac{\Phi^T e_x}{r_a} \cos \alpha + M_m^{-1}\frac{\Phi^T e_y}{r_a} \sin \alpha
\]

(48a)

\[
= -M_m^{-1}\frac{\phi_x}{r_a} \cos \alpha + M_m^{-1}\frac{\phi_y}{r_a} \sin \alpha
\]

(48b)

where \( \phi_x \) and \( \phi_y \) are vectors of modal components of \( x \) and \( y \) displacements at node \( n_1 \):

\[
\phi_x = \Phi^T e_x = [\phi_{x1}, \phi_{x2}, \cdots, \phi_{x150}]^T
\]

\[
\phi_y = \Phi^T e_y = [\phi_{y1}, \phi_{y2}, \cdots, \phi_{y150}]^T
\]

(49)

where \( \phi_{xi} \) and \( \phi_{yi} \) are \( x \) and \( y \) displacements of mode \( i \) at node \( n_1 \). Therefore, from Eqs. (43b) and (48b), one obtains

\[
B_s = \begin{bmatrix}
0 \\
-\frac{M_m^{-1}\phi_x}{r_a} \cos \alpha + M_m^{-1}\phi_y \sin \alpha
\end{bmatrix}
\]

(50)

The output matrix derivation is presented here for the wheel rate, \( \dot{\theta}_{pa} \). The wheel rotation is
\[
\dot{\theta}_{pa} = \frac{v_a}{r_a}
\]

where \(v_a\) is the tangential velocity of the wheel at the contact point [see Fig. 13(b)]. If \(v_x\) and \(v_y\) are \(x\) and \(y\) components of \(v_a\), and \(\alpha_a\) is the angle marked in this figure, then

\[
v_a = -v_x \cos \alpha_a + v_y \sin \alpha_a
\]

therefore,

\[
\dot{\theta}_{pa} = \left( -\frac{v_x}{r_a} \cos \alpha_a + \frac{v_y}{r_a} \sin \alpha_a \right) \dot{\theta}
\]

and in modal coordinates

\[
\dot{\theta}_{pa} = \left( -\frac{\Phi_x}{r_a} \cos \alpha_a + \frac{\Phi_y}{r_a} \sin \alpha_a \right) \dot{\theta}_m = \left( -\frac{\Phi_x}{r_a} \cos \alpha_a + \frac{\Phi_y}{r_a} \sin \alpha_a \right) \dot{\theta}_m
\]

Finally, the matrix \(C_s\), according to Eqs. (43b) and (53b), is

\[
C_s = \begin{bmatrix} 0 & -\frac{\Phi_x}{r_a} \cos \alpha_a + \frac{\Phi_y}{r_a} \sin \alpha_a \end{bmatrix}
\]

The structural model consists of \(m = 150\) modes or 300 states. Modes not participating in system dynamics are eliminated. Observability and controllability properties in the balanced representation are used to determine insignificant modes. The balanced representation [9] is a state-space representation with equally controllable and observable states. The Hankel singular value is a measure of the joint controllability and observability of each balanced state variable. The states with small Hankel singular values are deleted as weakly excited and weakly observed, causing minimal modeling error.

For flexible structures with small damping and distinct poles, the modal representation is almost balanced, c.f. [10–12], and each mode is considered for the reduction separately. For a structure with \(m\) modes, matrix \(B_s\) has \(2m\) rows, and \(C_s\) has \(2m\) columns. Denote \(b_s\) as the last \(m\) rows of \(B_s\), \(c_q\) as the first \(m\) columns of \(C_s\), and \(c_r\) as the last \(m\) columns of \(C_s\). Then \(b_s_i\) is the \(i\)th row of \(b_s\), \(c_q_i\) is the \(i\)th column of \(c_q\), and \(c_r_i\) is the \(i\)th column of \(c_r\). Denote \(\beta_{s_i}^2 = b_s_i b_s_i^T\), \(\alpha_{q_i} = c_q_i^T\), and \(\alpha_{r_i} = c_r_i^T\). The Hankel singular value for the \(i\)th mode is given in [11] and [12]:

\[
\gamma_i^2 = \frac{w_{b_s i} \beta_{s_i} \sqrt{w_{q_i}^2 \alpha_{q_i}^2 + w_{r_i}^2 \alpha_{r_i}^2}}{4 \omega_i^2}
\]

where the weighting factors \(w_{b_s i} > 0\), \(w_{q_i} > 0\), \(w_{r_i} > 0\), and \(i = 1, \cdots, m\).

Care should be taken when determining Hankel singular values. Units should be consistent; otherwise, some inputs or outputs receive more weight in Hankel singular-value determination than necessary. Consider, for example, the azimuth encoder reading in arcseconds and the elevation encoder reading in degrees. For the same angle, the numerical reading of the azimuth encoder is 3600 larger than the elevation encoder reading; hence, the elements for the azimuth output are much larger than those for elevation.
On the other hand, some variables need more attention than others: Pointing error and encoder readings are the most important factors in the antenna performance; hence, their importance has to be emphasized in mode evaluation. For consistency of units and importance of variables, the weighting factors $w_{bi}$, $w_{qi}$, and $w_{ri}$ are introduced. Typically, weights are set to 1.

For each mode, the Hankel singular value is determined and used to decide on the number of modes in the reduced structural model. For the rigid body modes, Hankel singular values tend to infinity; hence, rigid body modes are always included in the reduced model. Hankel singular values of the 150 modes of the antenna model are plotted in Fig. 14. The reduced order model consists of 24 modes: 2 rigid-body modes and 22 flexible modes.

The plots of the transfer function in azimuth and elevation (magnitude and phase) from the wheel (pinion) torque $T$ to the axis rate $\dot{\theta}$ are shown in Fig. 15. They show that the azimuth transfer function has low frequency resonances (about 1.2 and 2.2 Hz), which are absent in the elevation transfer function.
IV. Rate Loop Model

A rate loop block diagram is presented in Fig. 16, where $T_a$ and $T_e$ denote the drive torques, $\dot{\theta}_{pa}$ and $\dot{\theta}_{pe}$ denote pinion rates, and $r_a$ and $r_e$ are rate commands in azimuth and elevation, respectively. The state-space equations are combined from the state equations of the azimuth and elevation drives [see Eq. (38) and add subscript “a” for the azimuth drive and subscript “e” for the elevation drive] and the structure [see Eq. (44)]. Combining them, and defining the rate loop state vector $x_r$ as $x_r = [x_{da}, x_{de}, x_s]$, where $x_{da}$ and $x_{de}$ are azimuth and elevation drive states, one obtains the rate-loop state-space equations:

\[
\begin{align*}
\dot{x}_r &= A_r x_r + B_{ra} r_a + B_{re} r_e \\
y &= C_r x_r \\
\theta_a &= C_a x_r \\
\theta_e &= C_e x_r
\end{align*}
\]

(56a)

where

\[
A_r = \begin{bmatrix}
A_{da} & 0 & B_{da} C_{pa} \\
0 & A_{de} & B_{de} C_{pe} \\
B_{sa} C_{da} & B_{se} C_{de} & A_s
\end{bmatrix}
\]

(56b)

where $\theta_a$ and $\theta_e$ are azimuth and elevation encoder readings, $C_{pa}$ and $C_{pe}$ are the output matrices for the azimuth and elevation pinion rates, and $C_a$ and $C_e$ are the output matrices for the azimuth and elevation encoders, respectively.

Figure 17 shows the magnitude of the transfer function from the azimuth rate input $r_a$ to the azimuth encoder rate $\dot{\theta}_a$ (solid line) and the magnitude of the transfer function from the elevation rate input $r_e$ to the elevation encoder rate $\dot{\theta}_e$ (dashed line). The figure shows that the required identity relationship for low frequencies is not acquired. The magnitude of the transfer functions for frequencies less than 0.3 Hz is 0.74, below the required 1, due to inaccuracy in the model parameters (mainly in the hydraulic part). This drawback can be removed by the experimental investigation of the parameters of the hydraulic drives, such as motors, valves, and lines. However, this inaccuracy is corrected by the position feedback loop, as will be shown later. The high-frequency peaks in azimuth and elevation (8 Hz in azimuth and 20 Hz in elevation) are the gearbox resonances.
V. Position Loop Model

The rate loop system with the proportional and integral (PI) controller is shown in Fig. 18, where \( e_a \) and \( e_e \) are the azimuth and elevation servo errors. For the series connection of the rate loop system and the controller, as in Fig. 18(a), define the state vector \( x^T_a = [x_{ai} \ x_{ei} \ x_{ai}^T] \) with the new state variables \( x_{ei} \) and \( x_{ai} \) (integrals of the errors) such that

\[
\begin{align*}
\dot{x}_{ai} &= e_a \\
\dot{x}_{ei} &= e_e
\end{align*}
\]

(57)

The system output \( y \) is defined in Eq. (56a), the encoder output is \( \theta^T = [\theta_a \ \theta_e] \), and the input is \( e^T = [e_a \ e_e] \). The inputs to the rate loop systems are obtained from Fig. 18(a):

\[
\begin{align*}
r_a &= k_{pa}e_a + k_{ia}x_{ai} \\
r_e &= k_{pe}e_e + k_{ie}x_{ei}
\end{align*}
\]

(58)

where \( k_{pe}, k_{ie}, k_{pa}, \) and \( k_{ia} \) are proportional and integral parameters of the controllers. Combining the equations for the rate loop system with Eqs. (57) and (58), one obtains
Fig. 18. Position loop: (a) open and (b) closed.

\[
\begin{align*}
\dot{x}_o &= A_o x_o + B_o e \\
\theta &= C_o z_o \\
y &= C x_o
\end{align*}
\]

(59a)

where

\[
A_o = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ k_{ia}B_{ra} & k_{ie}B_{re} & A_r \end{bmatrix}
\]

\[
B_o = \begin{bmatrix} I & 0 \\ 0 & I \\ k_{pa}B_{ra} & k_{pe}B_{re} \end{bmatrix}
\]

(59b)

\[
C_o = \begin{bmatrix} 0 & 0 & C_a \\ 0 & 0 & C_e \end{bmatrix}
\]

\[
C = [0 & 0 & C_r]
\]

For the closed-loop system [see Fig. 18(b)],

\[
e = c - \theta
\]

(60)

where \(c^T = [c_a \ c_e] \) is a command signal in azimuth, \(c_a \), and in elevation, \(c_e \). Introducing Eq. (60) to Eq. (59), one obtains

\[
\begin{align*}
\dot{x}_{cl} &= A_{cl} x_{cl} + B_o c \\
y &= C x_{cl}
\end{align*}
\]

(61a)

where
\[ A_{cl} = A_0 - B_0 C_0 \] (61b)

The simulations shown in Figs. 19 through 22 have two sets of assumptions: (1) a proportional gain of 1 in azimuth and elevation and an integral gain of 0.3 and (2) a proportional gain of 0.7 in azimuth and elevation and an integral gain of 0.2. The closed-loop transfer functions from azimuth command to azimuth encoder are shown in Fig. 19(a), and those from elevation command to elevation encoder are shown in Fig. 19(b). They show a bandwidth of 0.1 Hz. The cross-coupling transfer functions from azimuth command to elevation encoder and from elevation command to azimuth encoder are shown in Fig. 20. They show low-level cross-coupling. The closed-loop step responses from azimuth command to azimuth encoder are shown in Fig. 21(a), and those from elevation command to elevation encoder are shown in Fig. 21(b). They show a 20- to 30-percent overshoot and a 7- to 9-s settling time. The cross-coupling from azimuth step command to elevation encoder and from elevation step command to azimuth encoder is shown in Fig. 22. The cross-coupling is of the order $10^{-3}$.

Fig. 19. Magnitude of the transfer function of the closed-loop system: (a) azimuth command to azimuth encoder and (b) elevation command to elevation encoder.
Fig. 20. Magnitude of the transfer function of the closed-loop system: azimuth command to elevation encoder and elevation command to azimuth encoder.

Fig. 21. Step responses of the closed-loop system: (a) azimuth command to azimuth encoder and (b) elevation command to elevation encoder.
VI. Wind Disturbance Simulations

Wind gust disturbances were modeled similarly to the DSS-13 antenna (see [13]) using the wind tunnel pressure distribution on the dish taken from Blaylock.\(^1\) Their time history is generated using the wind Davenport spectrum (see [14] and [15]), determined for the Goldstone site. The simulations for the 50 km/h wind gave the results listed in Table 4 and compared with the simulation results of the DSS-13 antenna. The table shows that DSS 14 has better disturbance rejection properties (at the encoders) than has the DSS-13 antenna.

VII. Conclusions

An analytical model of the DSS-14 antenna has been developed. The rate loop model consists of the structural model (derived from the finite element model), gearbox model, hydraulic servo, and electronic boxes. The position loop was closed, and the time and frequency responses were simulated. The wind pointing errors of the DSS-14 antenna have been simulated. The model allows for detailed simulation of antenna dynamics and for modifications and improvements to the antenna control system.

The simulations confirmed that the use of encoders located at drives limits the performance of the antenna (mainly by reducing its bandwidth to 0.1 Hz). The use of the master equatorial or new encoders

---

located close to the axes of rotation of the antenna (similarly to the 34-m antennas) would allow expansion
of the bandwidth to 0.7–1.0 Hz.

The antenna model needs further improvement. First, in this model, certain parameters of the hy-
draulic drive are known with rather poor accuracy, and it influences the accuracy of the antenna model. It is essential to use experimental techniques to get more precise values of the parameters. Secondly, the
RF pointing errors (in elevation and cross-elevation) of the antenna should be determined in order to
evaluate the precision of the antenna pointing.

Acknowledgments

The authors thank Robin Bruno and Douglas Strain for development of the finite
element model of the antenna structure, and Farrokh Baher and Abner Bernardo
for help in development of the electronic board model.

Transfer Function Derivation

Each component of the electronics board is composed of operational amplifiers (opamps), resistors, and capacitors. The basic configuration of an inverting opamp circuit is shown in Fig. A-1. The "+" terminal of the opamp is grounded; thus, the "−" terminal voltage is zero, called a virtual ground. In this situation, the currents \( i_1 \) and \( i_2 \) flowing through impedances \( Z_1 \) and \( Z_2 \) are equal to

\[
\begin{align*}
  i_1 &= \frac{v_{\text{in}}}{Z_1} \\
  i_2 &= \frac{v_{\text{out}}}{Z_2}
\end{align*}
\]  

(A-1)

and their sum is zero; that is, \( i_1 = -i_2 \). Introducing them to Eq. (A-1) gives

\[
v_{\text{out}} = -kv_{\text{in}}
\]  

(A-2a)

where

\[
k = \frac{Z_2}{Z_1}
\]  

(A-2b)
I. Transfer Function $G_{to}$

A schematic for the transfer function $G_{to}$ is shown in Fig. A-2(a), where the notation and the value of each element were taken from JPL Drawing 9479871D. This schematic can be simplified to the one shown in Fig. A-2(b). In this figure,

$$R_s = \left( R_{56}^{-1} + R_{57}^{-1} + R_{58}^{-1} + R_{59}^{-1} \right)^{-1} + R_{62} = 49.5 \text{ k}$

where $R_{56} = R_{57} = R_{58} = R_{59} = 100 \text{ k}$, and $R_{62} = 24.5 \text{ k}$. Thus, $R_s = 49.5 \text{ k}$. The component $Z_1$ is

$$Z_1 = R_{63} + \frac{R_{64}}{1 + R_{64}C_{40} s} \approx R_{63} + R_{64} = 91.1 \text{ k}$

where $R_{63} = 40 \text{ k}$, $R_{64} = 51.1 \text{ k}$, and $C_{40} = 0.15 \mu$F. The time constant $R_{64}C_{40} = 0.0077 \text{ s}$ is small, thus neglected. Denote $R_{mta} = 9.7 \text{ k}$ and $R_{mite} = 7.8 \text{ k}$ the motor resistances in azimuth and elevation, respectively, and $C_{41} = 0.15 \mu$F. Then, the component $Z_2$ for the azimuth drive is as follows:

$$Z_2 = \frac{R_{mta}}{1 + R_{mta}C_{41} s} \approx R_{mta} = 9.7 \text{ k}$

and for the elevation drive,

$$Z_2 = \frac{R_{mite}}{1 + R_{mite}C_{41} s} \approx R_{mite} = 7.8 \text{ k}$

The time constants $R_{mta}C_{41} = 0.0015 \text{ s}$ and $R_{mite}C_{41} = 0.0012 \text{ s}$ are of the order $10^{-3} \text{ s}$, thus considered small, and neglected.

The transfer function $G_{to}$ for azimuth is

$$G_{to} = \frac{R_p}{R_s + R_p} = \frac{8800}{49,500 + 8800} = 0.151$$

and for elevation, it is

---

2 JPL Drawing 9479871D (internal document), Jet Propulsion Laboratory, Pasadena, California.
where \( R_p = (Z_1^{-1} + Z_2^{-1})^{-1} = 8.8 \, \text{k\Omega} \) in azimuth and 7.2 \( \text{k\Omega} \) in elevation, while \( R_s = 49.5 \, \text{k\Omega} \).

![Fig. A-2. Schematic for the transfer function \( G_{\theta} \). (a) full and (b) simplified.](image)

### II. Transfer Functions \( G_{r1} \) and \( G_{r2} \)

The transfer functions \( G_{r1} \) and \( G_{r2} \) are determined simultaneously. Their schematic is given in Fig. A-3(a), the parameters parameters of which are

\[
\begin{aligned}
R_{45} &= 750 \, \text{k\Omega} \\
R_{50} &= 100 \, \text{k\Omega} \\
R_{51} &= 12.1 \, \text{k\Omega} \\
R_{52} &= 442 \, \text{k\Omega} \\
R_{53} &= 442 \, \text{k\Omega} \\
R_{65} &= 909 \, \text{k\Omega} \\
R_{66} &= 90.9 \, \text{k\Omega} \\
C_{31} &= 1 \, \mu\text{F} \\
C_{42} &= 0.1 \, \mu\text{F}
\end{aligned}
\]

(A-6)

The schematic from Fig. A-3(a) can be transformed to the form shown in Fig. A-3(b). The value of \( Z_3 \) is as follows:

\[
Z_3 = R_{66} + \frac{R_{65}}{1 + R_{65}C_{42}} \cong R_{66} + R_{65} = 10^6 \, \text{k\Omega}
\]

(A-7)
In this variable, the small time constant \( R_{65}C_{42} = 0.0909 \) s was ignored.

The value \( Z_4 \) is obtained as

\[
Z_4 = R_{53} + \frac{R_g}{1 + R_gC_{31}s} = 4.65 \times 10^5 \frac{1 + 0.400s}{1 + 4.205s}
\]  
(A-8)

where \( R_g = (R_{50} + R_{52} + R_{50}R_{52})/R_{51} = 4205 \) k\( \Omega \).

Having determined \( Z_3 \) and \( Z_4 \), the transfer functions \( G_{r1} \) (from \( v_r \) to \( v_s \)) and \( G_{r2} \) (from \( v_{i_0} \) to \( v_s \)) are obtained:

\[
\begin{align*}
G_{r1} &= \frac{Z_4}{R_{15}} = 6.20 \frac{G_o}{R_{15}} \\
G_{r2} &= -\frac{Z_4}{Z_3} = -4.65 \frac{G_o}{Z_3}
\end{align*}
\]  
(A-9)

where

\[
G_o = \frac{1 + 0.400s}{1 + 4.205s}
\]  
(A-10)

is the transfer function of a lag compensator.

![Fig. A-3. Schematic for the transfer functions \( G_{r1} \) and \( G_{r2} \): (a) full and (b) simplified.](image)

### III. Transfer Function \( G_s \)

The transfer function \( G_s \) is determined from the schematic in Fig. A-4(a), and is shown in compact form in Fig. A-4(b). For this schematic, \( R_{13} = 100 \) k\( \Omega \), \( R_{36} = 10 \) k\( \Omega \), \( R_{43} = 24.9 \) k\( \Omega \), and \( C_{18} = 0.1 \) \( \mu F \); therefore, one obtains

\[
Z_5 = \frac{R_{36}}{1 + R_{36}C_{18}s} \approx R_{36} = 10 \text{ k}\Omega
\]  
(A-11)

where \( R_{36}C_{18} = 0.0015 \text{ s} \approx 0 \). Since \( v_1 = v_sZ_5/R_{43} \), and \( i_s = v_1(Z_5^{-1} + R^{-1}) \), thus,
\[ G_s = \frac{i_s}{v_s} = \frac{R_{13} + Z_5}{R_{13}R_{43}} = 4.42 \times 10^{-5} \]  

(A-12)

Fig. A-4. Schematic for the transfer function \( G_s \): (a) full and (b) simplified.
