A push type fastener for fastening a movable structural part (41) to a fixed structural part (43), wherein the coupling and decoupling actions are both a push type operation, the fastener consisting of a plunger (12) having a shank (20) with a plunger head (18) at one end and a threaded end portion (26a) at the other end, an expandable grommet (14) adapted to receive the plunger shank (20) therethrough, and an attachable head (16) which is securable to the threaded end of the plunger shank (20). The fastener (10) requires each structural part (41, 43) to be provided with an aperture (45, 46) to be smaller than the aperture (46) in the second structural part. The plunger (12) is extensible through the grommet (14) and is structurally configured with an external camming surface (25) which is cooperatively engageable with internal surfaces (38) of the grommet so that when the plunger is inserted in the grommet, the relative positioning of said cooperable camming surfaces determines the expansion of the grommet. Coupling of the parts is effected when the grommet is inserted in the aperture (46) in the fixed structural part (43) and expanded by pushing the plunger head (18) and plunger at least a minimal distance through the grommet. Decoupling is effected by pushing the attachable head (16).

PUSH TYPE FASTENER

ORIGIN OF THE INVENTION

The invention described herein was made in the performance of work under a NASA contract and is subject to the provisions of Section 305 of the National Aeronautics and Space Act of 1958, Public Law 85-568 (72 Stat.435; 42U.S.C. 2457).

FIELD OF THE INVENTION

This invention relates to fasteners and, more particularly, to a plunger type fastener for attaching a readily removable part to a fixed part where access may be available from both sides of the coupling.

BACKGROUND OF THE INVENTION

Push type fasteners wherein the fastener is inserted through aligned holes on parts to be fastened together and pushed at one end to cause an expansion of a fastener component and thereby secure the parts together are well known. However, for decoupling the secured parts, the provisions of Section 305 of the National Aeronautics and Space Act of 1958, Public Law 85-568 (72 Stat.435; 42U.S.C. 2457).

The invention relates to a push type fastener wherein the fastener is inserted through aligned holes on parts to be fastened together and pushed at one end to cause an expansion of a fastener component and thereby secure the parts together. The invention is also provided with the unique feature that it can be decoupled without pulling on the plunger, since only a push on the rounded head is used to extract the plunger and thereby break the coupling. This makes the fastener ideal for low-dexterity situations while still retaining the small size and weight of the existing conventional "push to latch" and "pull to unlatch" fasteners.

FIG. 1 is an exploded view in perspective of the fastener of the invention being shown in proximity to two structural parts to be coupled;

FIG. 2 is another exploded view of the fastener of the invention showing internal surfaces of the expandable grommet and attachable head of the fastener;

FIG. 3 is a view of the fastener of the invention showing the plunger component of the fastener inserted to a limited extent in the fastener grommet and the grommet installed in unexpanded condition in a hole in a first structural part which is aligned with a second structural part to which it is to be coupled;

FIG. 4 is a view showing the fastener of FIG. 3 with unexpanded grommet installed in two structural parts to be coupled;

FIG. 5 is a view showing the fastener installed in fastened condition in two structural parts which are coupled thereby; and

FIG. 6 is an end view of the expandable grommet of the fastener of the invention.

SUMMARY OF THE INVENTION

The invention relates to a push type fastener wherein the coupling and decoupling actions are a push-type operation. The latch consists of a plunger component having a rounded end and a threaded end, an expandable grommet, and a rounded head which is securable to the threaded end of the plunger. The plunger is extensible through the grommet and is structurally configured with an external camming surface which is cooperatively engageable with an internal surface of the grommet so that when the plunger is inserted in the grommet, the relative positioning of said cooperatively engageable surfaces determines the expansion of the grommet.

For attaching a removable part to a fixed part by the fastener of this invention, it is necessary that the two said parts must be provided with holes through which the fastener can be inserted to effect their attachment. The rounded head, which is securable to one end of the plunger, is of a slightly smaller size than the hole through the fixed part so that it easily passes therethrough.

As a preliminary step in a fastening operation, the grommet is inserted into a hole provided in the removable part. A radial flange on the grommet prevents the grommet from passing completely through the hole in the removable part. The plunger is then inserted, threaded end first into the grommet to an extent such that the grommet remains in unexpanded condition. The rounded head, which is slightly smaller than the hole through the fixed part, is then attached to the threaded end of the plunger. The removable part is then aligned with the fixed part by alignment of the holes provided respectively therein, and the fastener with the grommet in non-expanded condition thereon, is then inserted rounded head first through the hole in the fixed part to where the grommet flange engages the removable part.

To accomplish fastening of the two parts, simply pushing the plunger head causes the expansion of the grommet on the side of the fixed part opposite the radial flange thereby clamping and fastening the two parts together. The fastener is also provided with the unique feature that it can be decoupled without pulling on the plunger, since only a push on the rounded head is used to extract the plunger and thereby break the coupling. This makes the fastener ideal for low-dexterity situations while still retaining the small size and weight of the existing conventional "push to latch" and "pull to unlatch" fasteners.

DETAILED DESCRIPTION OF THE INVENTION

Referring to FIG. 1, there is shown in exploded view, a fastener 10 which comprises a plunger 12, an expandable grommet 14 and a readily attachable rounded ball head 16. The plunger 12 is provided with a cylindrical shank portion 20 of circular radial cross section and a large rounded manipulating head 18 integrally attached thereto at one end. The shank portion 20 comprises a large diameter section 22 which connects to the manipulating head 18, an intermediate diameter section 23, a large diameter section 24 equal in diameter to the section 22, and a reduced diameter section 26. The reduced section 26 has a threaded end portion 26a, and a smooth surface portion 26b with an annular radial flange 28 located intermediate the threaded end of the plunger and the large diameter section 24. The flange 28 serves as a stop for the threads on the threaded end of the plunger.

The grommet 14 is provided with a large annular radial flange 30 at one end 31, a central cylindrical section 32 of circular cross section, an axial opening 33 extending therethrough, and two pair of flexible jaws or tabs 34, each jaw of which is integrally connected at one end to the cylindrical section 32. The jaws of each pair are in diametrically opposed relation to one another, and are formed by four slots 35 extending from the opposite end 37 of the grommet to its cylindrical section 32. When viewed in a transverse radial plane through the grommet, the slots are at locations in 90° angular relation. Each jaw 34 has an external tapered surface 36 which extends from the free end of the jaw in a diverg-
The axial opening 33 through the grommet flange 30 and its cylindrical section 32 is circular in radial transverse cross section and of a complementary size and shape sufficient to accommodate the enlarged diameter portions 24, 22 of the plunger in an easy sliding fit therein. As shown in FIG. 2, the inner surface of each jaw 34 comprises a cylindrical portion, which is quarter-circular in transverse cross section and extends from the grommet end 31 at the opening 33 through the grommet section 32 to an inner camming surface 38 which tapers and converges inwardly towards the end of the jaw 34. Each tapered surface 38 is approximately one-quarter of a frusto-conical surface which is divided by a pair of diametral planes through its longitudinal axis and in orthogonal relationship to one another as best seen in FIG. 4.

The radial flange 16 is of spherical shape truncated by an annular planar surface 15 which approximates an annular chamfered surface 25 which is provided on the end of the large diameter shank section 24 and which faces the plunger flange 28. This head 16 is provided with an inwardly extending blind bored 17 having an internally threaded section 19 and an enlarged diameter threaded-relief smooth bore section 21 connecting therewith which opens at the planar surface 15.

The fastener 10 of the invention is particularly intended for use in removably joining a perforated first structural member, such as a panel 41, to a perforated second structural member, such as a fixed panel, such as holes 45 or other hostile environments, or if the person is handi-capped. It is also well suited for fastener applications in underwater operations and in extra-vehicular activities in manned space operations. Although a relatively snug fit of fastener parts is desirable but not always present, misalign-ment tolerance is provided by a slightly looser fit between planner, grommet and the holes in the parts to be attached.

It is also to be understood that the foregoing description of a preferred embodiment of this invention has been presented for purposes of explanation and illustration and is not intended to limit the invention to the precise form disclosed. For example, the rounded heads could be other than spherical, and the grommet flange, could be much larger and of different shape than shown herein. The grommet might also be provided with one or several pairs of jaws rather than two. The rounded heads could also be attached to the plunger by means other than threads. If the parts are plastic, the plunger tip could terminate in a small spherical tip adapted to be snapped into a corresponding receptacle provided in the truncated rounded head. Accordingly, it is to be appreciated that many changes may be made in the structure and materials by those skilled in the art without departing from the spirit of the invention.

I claim:

1. A fastener for joining a removably structural part having a first aperture therein in fixed relation to a second structural part having a second aperture thereto wherein said structural parts are adapted to be engaged with said apertures aligned with one another, said fastener comprising:

A plunger element including an elongate shank having a threaded end portion at one end and an enlarged manipulative plunger head at the other end, said shank having an enlarged diameter portion intermediate its ends with an annular chamfered camming surface on
fastener for joining a removable structural part to a second structural part; said grommet having a first aperture therein to a second structural part, said grommet having an external radial flange of a size larger than said first aperture so as to be impassable therethrough, said grommet having at least one pair of movable jaws which form a split body portion of said grommet, each said jaw having an internal bevelled camming surface, said jaw camming surfaces being constructed and arranged for cooperative camming engagement when said plunger shank is inserted in the grommet beyond a predetermined distance, whereby when said grommet is inserted through the aperture in said removable structural part and the plunger shank then inserted into said grommet, the attachable head may be secured on said plunger shank, said attachable head being of a size so as to be freely passable through said grommet so that said grommet may be pushed in axial movement through the grommet towards said second structural part to cause the grommet jaws to open outwardly and expand the grommet to thereby couple said structural parts, said fastener being releasable by applying a force on said enlarged attachable head to move said shank in axial movement towards said removable part.

2. A fastener for joining a removable structural part having a first aperture therein to a second structural part having a second aperture and wherein said structural parts are adapted to be placed in engagement with said apertures aligned with one another, said fastener comprising:

a plunger element including an elongate shank having a threaded end portion at one end, an enlarged plunger head therethrough; an expansible grommet having an opening therethrough, said grommet having at least one pair of movable jaws which form a split body portion of said grommet, each said jaw having an internal bevelled camming surface, said jaw camming surfaces being constructed and arranged for cooperative camming engagement when said plunger shank is inserted in the grommet beyond a predetermined distance, whereby when said grommet is inserted through the aperture in said removable part, said plunger shank is inserted into said grommet, the attachable head may be secured on said plunger shank, said attachable head being of a size so as to be freely passable through said grommet so that said grommet may be pushed in axial movement through the grommet towards said second structural part to cause the grommet jaws to open outwardly and expand the grommet to thereby couple said structural parts, said fastener being releasable by applying a force on said enlarged attachable head to move said shank in axial movement towards said removable part.

3. A fastener for joining a removable structural part having a first aperture therein to a second structural part having a second aperture and wherein said structural parts are adapted to be placed in engagement with said apertures aligned with one another, said fastener comprising:

a plunger element including an elongate shank having a threaded end portion at one end, an enlarged plunger head at its other end and an enlarged diameter portion intermediate its ends with an annular camming surface thereon which faces toward the other end of said shank; an expansible grommet having a longitudinal axial opening extending therethrough of a size adapted to receive said shank therein but insufficient to receive the plunger head therethrough; an enlarged rounded head attachable to said other end of said plunger shank, said attachable head being of a size larger than said opening in the grommet but smaller than second aperture in said second structural part so as to be freely passable through said aperture in said second structural part; cooperative means on said enlarged rounded head and said shank for attaching said enlarged rounded head to said other end of the shank, said grommet having an enlarged diameter portion of a size larger than said first aperture and a reduced diameter portion smaller than said first aperture, said reduced diameter portion including at least one pair of movable jaws and each said jaw having an internal bevelled camming surface, said jaw camming surfaces being constructed and arranged for cooperative camming engagement with said plunger shank, said plunger shank being inserted in the grommet beyond a predetermined distance, whereby when said grommet is inserted through the aperture in said removable structural part and said plunger shank is inserted into said grommet, the attachable rounded head may be attached to said other end of said shank and said plunger may be pushed in axial movement through the grommet towards said second structural part to cause the grommet jaws to open outwardly and expand the grommet to thereby couple said structural parts, said fastener being releasable by applying a force on said enlarged attachable head to move said shank in axial movement towards said removable part.

4. A fastener for joining a removable structural part to a second structural part as set forth in claim 3 wherein said grommet is provided with two pairs of movable jaws which form a split body portion of said grommet, each jaw of a pair being in diametrically opposed relation to the other jaw of said pair.

5. A fastener for joining a removable structural part to a second structural part as set forth in claim 4 wherein each said jaw as oriented in a transverse radial plane through said split body portion is located in 90° angular relation to the next adjacent jaws.
