A rotary blood pump includes a pump housing for receiving integrated circuits. A plurality of magnets are disposed in back emf integrated circuit regulates rotor operation and a microcomputer may be used to control one or more back emf integrated circuits. A plurality of magnets are disposed in each of a plurality of impeller blades with a small air gap. A stator may be axially adjusted on the pump housing to absorb bearing load and maximize pump efficiency.

ROTARY BLOOD PUMP

FIELD OF THE INVENTION

The invention described herein was made in the performance of work under a NASA contract and is subject to the provisions of Section 305 of the National Aeronautics and Space Act of 1958, Public Law 85-568 (72 Stat. 435; 42 U.S.C. 2457).

TECHNICAL FIELD

The present invention relates generally to rotary blood pumps. More specifically, the present invention relates to an axial flow ventricle assist blood pump.

BACKGROUND OF THE INVENTION

Ventricle assist devices are frequently used to boost blood circulation to assist a heart which still functions but is not pumping sufficient blood for adequate circulation. Rotary pumps are often the preferred type of pump for use as a ventricle assist device compared to other types of pumps which may use pistons, rollers, diaphragms, or compliance chambers. This is partially because rotary pumps may be manufactured at a relatively low cost and are typically less complex than other types of pumps. Other types of blood pumps may cost up to $50,000 per unit and, due to financial limitations, are therefore not available for use upon the large population which could benefit from such pumps. Rotary blood pumps are increasingly used not only for ventricular assist applications, but also for cardiopulmonary bypass procedures and percutaneous cardiopulmonary support applications in emergency cases.

Clinical uses of rotary pumps are conventionally limited to a few days due to shortcomings of these pumps. A non-comprehensive list of such problems or shortcomings would include the following: (1) blood damage which may occur when blood comes into contact with rotor bearings, (2) the need for bearing purge systems which may require percutaneous (through the skin) saline solution pump systems, (3) bearing seizure resulting from the considerable thrust and torque loads, or from dried blood sticking on the bearing surfaces, (4) problems of blood damage (hemolysis) and blood clotting (thrombosis) caused by relative rotational movement of the components of the pump, (5) pump and control size and shape limitations necessary for implantation or convenient mobility, (6) weight limitations for implantation to avoid tearing of implant grafts due to inertia of sudden movement, (7) difficulty in coordinating and optimizing the many pump design parameters which may affect hemolysis, (8) high power consumption that requires a larger power supply, (9) motor inefficiency caused by a large air gap between motor windings and drive magnets, (10) heat flow from the device to the body, (11) complex Hall Effect sensors/electronics for rotary control, (12) the substantial desire for minimizing percutaneous (through the skin) insertions, including support lines and tubes, and (13) large pump and related hose internal volume which may cause an initial shock when filled with saline solution while starting the pump.

Although a significant amount of effort has been applied to solving the problems associated with rotary pumps, there is still a great demand for a safe, reliable, and durable blood pump that may be used for longer term applications. The estimated need for a simple and long term ventricle assist device (VAD) is presently projected at between 50,000 and 100,000 patients per year in the United States alone.

The following patents describe attempts made to solve problems associated with rotary blood pumps, including ventricle assist devices.

U.S. Pat. No. 4,625,712 to R. K. Wampler discloses a full-flow cardiac assist device for cardiogenic shock patients which may be inserted into the heart through the femoral artery and driven via a flexible cable from an external power source. A catheter attached to the pump supplies the pump bearings with a blood-compatible purge fluid to prevent thrombus formation and the introduction of blood elements between rotating and stationary elements. Due to the very small diameter of the pump, rotational speeds on the order of 10,000 to 20,000 rpm are used to produce a blood flow of about four liters per minute.

U.S. Pat. No. 4,957,504 to W. M. Charchlack discloses an implantable blood pump for providing either continuous or pulsatile blood flow to the heart. The pump includes a stator having a cylindrical opening, an annular array of electromagnets disposed in a circle about the stator concentric with the cylindrical opening, a bearing carried by the stator and extending across the cylindrical opening, and a rotor supported by the bearing. The rotor is in the form of an Archimedes screw and has a permanent magnet in its periphery which lies in the same plane as the circular array of electromagnets for being driven in stepper motor fashion.

U.S. Pat. No. 4,944,722 to J. W. Carriker discloses a percutaneously insertable intravascular axial flow blood pump with a rotor extension and drive cable fitting designed so that the thrust bearing surfaces of the purge seal and cable fitting can be preloaded.

U.S. Pat. No. 4,817,586 to R. K. Wampler discloses an intravascular flow blood pump having blood exit apertures in the cylindrical outside wall of the pump housing between the rotor blades and the rotor journal bearing.

U.S. Pat. No. 4,908,012 to Moise et al. discloses an implantable ventricular assist system having a high-speed axial flow blood pump. The pump includes a blood tube in which the pump rotor and stator are coaxially contained, and a motor stator surrounding the blood duct. A permanent magnet rotor motor is integral with the pump rotor. Purge fluid for the hydrodynamic bearings of the device and power for the motor are preferably percutaneously introduced from extra-corporal sources worn by the patient.

U.S. Pat. No. 4,779,614 to J. C. Moise discloses an implantable axial flow blood pump which includes a magnetically suspended rotor of a relative small diameter disposed without bearings in a cylindrical blood conduit. Neodymium-boron-iron rotor magnets allow a substantial gap between the static motor armature and the rotor. Magnetically permeable strips in opposite ends of the pump stator blades transmit to Hall sensors the variations in an annular magnetic field surrounding the rotor and adjacent the ends of the pump stator blades.

U.S. Pat. No. 5,049,134 to Golding et al. discloses a seal free centrifugal impeller supported in a pump housing by fluid bearings through which a blood flow passageway is provided.

U.S. Pat. No. 4,382,199 to M. S. Isacson discloses a hydrodynamic bearing system for use with a left ventricle assist device. The bearings are formed by the fluid in the gap between the rotor and the stator.

U.S. Pat. No. 4,135,253 to Reich et al. discloses a centrifugal blood pump provided with a magnetic drive system which permits a synchronous magnetic coupling with a separate power unit disposed immediately adjacent the pump housing but outside of the skin surface. The pump...
has a single moving part which includes the combination of
an impeller connected to a magnetic drive rotor. The mag-
netic drive system floats on a fluid surface of saline solution.

U.S. Pat. No. 4,507,048 to J. Belenger discloses a cen-
trifugal blood pump with a bell-shaped housing having a
suction inlet at the apex and a tangential outlet adjacent the
base. A conical rotator is driven by spaced permanent
magnets embedded in the base of the rotator and an exter-
nally generated rotating magnetic field.

U.S. Pat. No. 4,688,998 to Olsen et al. discloses a pump
with a magnetically suspended and magnetically rotated
impeller. The impeller may be configured for axial flow with
a hollow, cylindrical-type impeller with impeller vanes on
the internal surface thereof. The impeller includes a plurality
of internally embedded, permanent magnets that cooperate
with electromagnets for drive and position control of the
impeller.

U.S. Pat. No. 4,763,032 to Brann et al. discloses a mag-
netic motor bearing for suspending a rotor for an axial or
radial-centrifugal blood pump in a contact-free manner, and
comprising a permanent and electromagnetic arrangement.
U.S. Pat. No. 4,846,152 to Wampler et al. discloses a
miniature high-speed intravascular blood pump with two
rows of rotor blades and a single row of stator blades within
a tubular housing. The first row of blades has no provision
for a variable pitch, but produces a mixed centrifugal and
axial flow by increasing hub diameter. The second row of
blades is axially spaced from the first row, and produces a
purely axial flow. The stator blades are reverse twisted to
straighten and slow the blood flow.

U.S. Pat. No. 4,944,748 to Brann et al. discloses an
impeller in a blood pump supported by permanent magnets
on the impeller and pump housing, which are stabilized by
an electromagnet on the pump housing. The impeller is
rotated magnetically, and stator coils in the housing are
supplied with electric currents having a frequency and
amplitude adjusted in relation to blood pressure at the pump
inlet.

U.S. Pat. No. 4,994,078 to R. K. Jarvik discloses an
electrically powered, rotary hydrodynamic pump having
motor windings and laminations disposed radially about an
anular blood channel, and having a motor rotor disposed
therein such that an anular blood channel passes through
the gap between the motor rotor and the windings.

U.S. Pat. No. 5,055,005 to Kleta-Liska discloses a fluid
pump with an electromagnetically driven rotary impeller
levitated by localized opposed fluid forces.

In spite of the effort evidenced by the above patents, there
remains the need for an improved rotary pump for use as a
ventricle assist device that is reliable, compact, requires
limited percutaneous insertions, and produces fewer blood
damage problems. Those skilled in the art will appreciate the
features of the present invention which addresses these and
other problems.

STATEMENT OF THE INVENTION

The present invention provides a rotary blood pump
which includes a pump housing defining a blood flow path
therethrough. A motor having a first stator field winding
is used to produce a first stator field magnetic field. A first rotor
is mounted within the pump housing for rotation in response
to the first stator field magnetic field. The first rotor carries a blade
thereon to propel blood through the pump housing along the
blood flow path. At least one magnet is secured to the first
rotor and produces a first rotor magnetic field that passes
through the first stator field winding during rotation of the
first rotor to thereby induce a back emf within the first stator
field winding. Back emf sensor circuitry connected to the
first stator field winding senses back emf produced during
the rotation of the first rotor within the pump housing. In one
embodiment of the present invention, at least one magnet is
implanted in each of a plurality of impeller blades to produce
rotational movement of the rotor.

The rotary pump also includes, in a preferred embeddi-
ing, an inducer portion of the rotor having a plurality of
inducer blades equidistantly disposed about a circumference
of the rotor with each inducer blade having a variable pitch
along its axial length. An interconnection blade portion
connects at least one of the inducer blades to at least one
impeller blade to form a continuous blade extending through
said inducer and impeller portions of the rotor.

The rotary pump preferably includes a first rotor bearing
for rotatably supporting the rotor within the pump housing.
The rotor bearing includes a curved bearing surface fixed
with respect to the pump housing. The fixed bearing surface
receives a rotating member having a rotating curved bearing
surface. The fixed bearing surface and the rotating curved
bearing surface define a bearing chamber which is filled with
bio-compatible material.

An object of the present invention is to provide an
improved rotary blood pump.

A further object is to provide an improved control circuit
for controlling a rotor within the pump in response to a back
emf produced in stator windings.

Another object is to provide an improved bearing for
which cross-linked blood forms a bearing surface and blood
seal.

Yet another object of the present invention is to provide a
method for optimizing pump parameters to reduce blood
hemolysis.

A feature of the present invention is a reduced air gap
between permanent magnets on the rotor and the stator
winding.

Another feature of the present invention is an impeller
having a variable pitch blade.

Another feature of the present invention is a back emf
integrated circuit for controlling rotor operation.

An advantage of the present invention is improved rotor
control.

Another advantage of the present invention is quantifiably
reduced damage to blood.

Yet another advantage of the present invention is an
elimination of the need for a bearing purge system requiring
saline carrying tubes penetrating through the skin.

Other objects, features and intended advantages of the
present invention will be readily apparent by the references
to the following detailed description in connection with the
accompanying drawings and claims.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is an elevational view, partially in section, of a
rotary blood pump in accord with the present invention;

FIG. 2 is an end view of a stator showing stator lamin-
ations stacked to form a skewed stator;

FIG. 2A is an elevational view indicating the skewed path
of stator field windings through the stator;

FIG. 3 is an elevational view, partially in section, of an
alternative embodiment rotary blood pump having distinct
impeller and inducer blades;
FIG. 4 is a cross-sectional view of a portion of an impeller showing non-radiused blade tips;
FIG. 5 is a block diagram of a control system including a back emf integrated circuit and a microprocessor;
FIG. 6A is an elevational view, partially in section, of a ball-socket rotor bearing having a bearing chamber filled with bio-compatible material;
FIG. 6B is an elevational view, partially in section, of a shaft journal rotor bearing having a bearing chamber filled with bio-compatible material;
FIG. 6C is an elevational view, partially in section, of a rotor bearing shaft having blood flow passages along the shaft periphery;
FIG. 6D is a cross-sectional view along line 6E—6E;
FIG. 6F is an elevational view, partially in section, of a rotor bearing for supporting the rotor in cantilevered fashion;
FIG. 7 is a chart showing optimum pump parameter components determined from methods of optimizing pump parameters to minimize hemolysis;
FIG. 8 shows the test matrix of the present invention for optimizing pump parameters to minimize hemolysis while maximizing pump efficiency;
FIG. 9 is a graph showing change in inducer blade pitch along the axial length of the inducer; and
FIG. 10 is an elevational view, partially in section, of two axially spaced pumps for separate or combined operation in accord with the present invention.

While the invention will be described in connection with the presently preferred embodiments, it will be understood that it is not intended to limit the invention to these embodiments. On the contrary, it is intended to cover all alternatives, modifications, and equivalents as may be included in the spirit of the invention.

BRIEF DESCRIPTION OF PREFERRED EMBODIMENTS

The present invention describes a rotary blood pump which has an improved rotor control system. The rotary pump has a pump blade geometry optimized by a method of the present invention to provide high pump efficiency while minimizing hemolysis and thrombus formation (hemolysis is defined quantitatively hereinabove). The pump requires less than 10 watts of power to pump 5 liters/minute against a pressure head of 100 mm Hg. A preferred embodiment of the pump weighs 53 grams, has a length of 75 mm, and a diameter of 25 mm. An index of hemolysis of 0.018 g/100 liters pumped is achieved, although using the method of this invention, further reductions are possible. For reference, a more standard roller pump has an index of hemolysis of 0.06 g/100 liters. Published articles concerning aspects of the present invention are hereby incorporated by reference and include the following: (1) "In Vitro Performance of the Baylor/NASA Axial Flow Pump", Artificial Organs, 1993 Volume 17, number 7, page 609–613; (2) "Development of Baylor/NASA Axial Flow VAD", Artificial Organs, 1993, Volume 17, page 469.

Referring now to the drawings, and more particularly to FIG. 1, there is shown a rotary blood pump 10 in accord with the present invention. Blood pump 10 includes a preferably metallic tubular pump housing 12 which is, in a preferred embodiment, a straight-sided cylinder. Pump housing 12 has a smooth inner bore wall 15 to minimize thrombus formation. Pump housing 12 defines a blood flow path 13 therethrough in the direction indicated by blood flow arrows shown in FIG. 1.

Front and rear clamps 14 and 16, respectively, are used to secure flow straightener 18 and diffuser 20 within pump housing 12. Pump housing 12 is sufficiently thin-walled so that the tightening of clamps 14 and 16 with clamp screws 22 locally deforms pump housing 12 about flow straightener 18 and diffuser 20 to affix these components in position. The clamps provide a very convenient means of securing the rotors together. Alternatively, other means for securing these components could be used, such as spot welding, fasteners, and interference fit.

Flow straightener 18 serves two basic functions: (1) it straightens blood flow to reduce hemolysis while improving pump efficiency, and (2) it provides a support structure for front ball-socket bearing assembly 24, as discussed hereinafter. By straightening the flow of blood as it initially flows into the entrance 36 of pump 10, hydraulic efficiency is increased. Straightening the blood flow also reduces turbulence to increase the pump pressure. FIG. 7 lists optimal values and permissible pump parameter ranges for the flow straightener 18 and the other pump components.

Flow straightener 18 preferably has four fixed blades 26, but could have only two blades. Too many blades impede blood flow, while too few blades reduce pump efficiency. For purposes of lowering thrombosis, the front edge 28 of each blade 26 is sloped from inner housing wall 15 to flow straightener hub 32 so that blood trauma by contact with blades 26 is minimized. Also to reduce blood trauma, flow straightener hub 32 is cylindrical with a rounded leading surface 34. Surface 34 may also be hyperbolical or generally bullet-shaped for this purpose. An alternative embodiment flow straightener 18a is shown in FIG. 3, and does not have the sloping front edge blades.

The preferred angle of attack of blades 26 is 90°, i.e., the blades would intersect a plane transverse to cylindrical housing 12 at an angle of 90°. This reference for the angle of attack or pitch of the blades will be used throughout this specification.

Flow straightener 18 is preferably metallic, but may also be formed of plastic. If formed of plastic and secured in place by clamp 14, it is necessary to reinforce flow straightener 18 with, for instance, metallic supports to prevent plastic creep deformation. The plastic creep deformation phenomena might otherwise eventually cause flow straightener 18 to come loose from clamp 14. Reinforcement is also necessary with respect to other clamped pump components.

Diffuser 20 also has two basic purposes: (1) it de-accelerates and redirects the outflow at blood flow path exit 40 axially to boost pump performance, and (2) it serves as a support structure for the rear rotor bearing 42. Diffuser 20 preferably has from 5 to 8 fixed blades 38, with 6 blades being presently preferred. Blades 38 are fixably engaged with pump housing 12 after rear clamp 16 is tightened by screw 22.

To perform the function of de-acceleration and axial redirection of blood flow, each diffuser blade 38 has an entrance angle of from about 10° to 25° for slowing the blood down, and an outlet angle of from about 80° to 90° for redirecting blood flow in an axial direction. Presently preferred blade geometry is listed in FIG. 7 and includes an
Based on the type and function of the blades disposed in an axial flow pump, along with an impeller portion, the number of fixed blades tends to decrease hemolysis.

Rotor 46 is supported for rotary movement with pump housing 12 by front and rear bearings 24 and 42, respectively. Rotor 46 is divided into two portions along its axis based on the type and function of the blades disposed thereon. Inducer portion 48 is disposed in the front part of rotor 46, i.e., nearer to the pump inlet 36. Impeller portion 50 is disposed in the rear part of rotor 46 closer to pump outlet 40. It has been found that including an inducer portion in an axial flow pump, along with an impeller portion, significantly reduces hemolysis.

FIG. 3 shows an alternative embodiment of the present invention which provides for two distinct sets of axially spaced blades which more clearly distinguish the inducer portion of the rotor from the impeller portion of the rotor. Corresponding components of pump 10 and 10a are given the same number, with the difference of an "a" suffix to distinguish the components for comparison purposes as necessary. A reference to one number is therefore a reference to its corresponding number in this specification, unless otherwise stated. Where components are substantially different between the two pump versions, completely new numbers are assigned. In pump 10a, inducer portion 48a is separated from impeller portion 50a of rotor 46a by gap 49a, which is preferably less than 0.10 inches. Inducer blade 52a may be tapered (not shown) at forward end 56a so that blade 52a has a smaller radial length at forward end 56a, perhaps even blending into hub 73. However, using the method of the present invention, it has been found that a continuous blade pump has even more reduced levels of hemolysis than the non-continuous blade pump 10a. Thus, pump 10 shown in FIG. 1 is the presently preferred embodiment.

Inducer blades 52 on inducer 53 have a variable pitch along their axial length. FIG. 9 shows an inducer blade angle profile that plots angle of attack in degrees versus axial position on inducer 53 in inches. It was found that the inducer portion 48 reduced hemolysis by approximately 45% from a pump design without the inducer. Hydraulic efficiency was also increased as the rotation speed required to pump 5 liters/min of blood at 100 mm Hg. dropped from 12,600 rpm to 10,800 rpm. The inducer blades 52 pre-rotate the blood before it enters the main pumping or impeller 54 to reduce hemolysis.

Inducer blades 52 also achieve a pumping action that effectively produces a two-stage, increased efficiency pump. Optimum inducer blade geometry for minimal hemolysis and maximum pump efficiency is listed for specific parts of inducer blade 52 in the chart of FIG. 7. Thus, the entrance angle of leading end 56 of inducer blade 52 is preferably 10°, but has a preferred range from about 10° to 20°. The shallow entrance angle effectively engages the blood for movement without damaging the blood. The pitch of inducer blade 52 continues to change along its axial length, and preferably is about 30° at midpoint 58 of the blade. The tailing end 60 of inducer blade 52 preferably has an outlet angle of 20°. This variable pitch is described in FIG. 9, which shows how pitch varies with the axial length of inducer 53. As well, it is desired that inducer blades have a wrap of preferably 240° around rotor 46. The presently preferred overlap of each blade over other blades is 120° or a 50% overlap. The chart of FIG. 7 provides a complete listing of relevant pump parameter values, including preferred ranges of operation.

Outside of these ranges, pump efficiency drops and/or blood damage is more likely to occur.

Pump 10 includes an interconnecting blade portion 62 which is not included in pump 10a. Although the two-stage pump 10a produces significantly reduced hemolysis and efficient pump operation compared to a single stage pump, it has been discovered that by interconnecting inducer blades 52 with impeller blades 54 with interconnecting blade portion 62, hemolysis may be reduced to even lower levels while maintaining efficient pump operation.

Impeller blades 54 on impeller 55 have an entrance angle in leading end region 64 of preferably 20°. This may be seen more clearly in FIG. 3, which has no interconnecting blade portion 62. The entrance angle preferably smoothly tapers to an optimum preferred outlet angle of 90° at blade tailing end region 66. The optimum ranges of operation for the entrance and outlet angles is given in FIG. 7.

Impeller blades 54 include axially longer impeller blades, such as longer blade 68, and axially shorter impeller blades, such as shorter blade 70. The alternate long and short blade arrangement on impeller 55 accommodates multiple magnetic poles for electric motor operation as discussed herein, and still maintains adequate flow area through impeller 55. Presently, the preferred number of impeller blades is six, but a range from two to six blades provides permissible pump efficiency. If impeller 55 included six axially longer blades, such as longer blade 68, the flow area through impeller portion 50 is restricted to such an extent that the blades actually begin to block the flow they are intended to produce.

Using the method of this invention, it was unexpectedly discovered that hemolysis does not necessarily increase with the number of blades, as anticipated. The alternating long-short blade arrangement of the six bladed impeller of the present invention does not cause hemolysis any more significantly than a two-bladed impeller. In some cases, an impeller with four long blades may cause more hemolysis than either a two or six bladed impeller. It is possible that the degree of hemolysis depends more on the number of long blades rather than the total number of blades.

FIG. 4 shows a portion of impeller 55 in cross-section to illustrate the substantially flat, non-radial blade tips 72. It has been unexpectedly found, using the method of this invention, that flat or substantially flat, non-radial blade tips have substantially the same pump response, but do not produce significantly different hemolysis results from rounded or radiused blade tips. It was anticipated that flat blade tips would produce higher hemolysis. Because flat blade tips are less expensive to manufacture in conjunction with magnets to be used in the blades as discussed herein, flat blade tips comprise the presently preferred embodiment. Further test results are discussed in greater detail in the previously noted articles incorporated herein by reference.

FIG. 4 also illustrates a preferred rotor hub 73 with outside diameter 74 compared to the overall outside diameter 76 of inducer 53 and/or impeller 55. The preferred ratio is 0.48, although a range of 0.45 to 0.55 permits excellent pump operation. If the hub is smaller than permitted by this range, blood becomes excessively swirled and may tend to recirculate within pump 10 in the wrong flow direction to possibly damage the blood as well as reduce pump efficiency. If the hub is too large so as to be outside of this range, the hub tends to block flow through the pump 10.

The radial clearance 78 between inducer 53 and/or impeller 55 with respect to the pump housing inner wall 15 is...
preferably in the range of about 0.003 inches to 0.015 inches. Using a test matrix as per the method of this invention, it was unexpectedly discovered that smaller radial clearances lowered hemolysis. It was expected that smaller radial clearances would produce greater blood damage due to higher shear stresses on the blood. The presently preferred radial clearance is about 0.005 inches. Axial clearances between components, such as flow straightener 18, rotor 46, and diffuser 20, are shown in FIG. 7. Axial clearances should be within the ranges shown to improve pump efficiency and to reduce hemolysis.

In order to reduce the air gap between stator 80 and magnets 82, the magnets are preferably sealingly mounted within impeller blades 54. Reducing the air gap between the stator 80 and the magnets 82 increases motor efficiency, because magnetic flux is not as diffused as in motor designs with large air gaps. The preferred radial spacing or air gap between magnets 82 and stator 80 is from 0.01 inches to 0.025 inches. Magnets 82 are preferably rare earth magnets because of the higher magnetic flux produced by such magnets. Each magnet 82 is encapsulated in an individual pocket 84 to eliminate corrosion. Because magnets are individualized, motor torque and rotor weight can be easily adjusted in the manufacturing stage to provide motors that are tailored to the type of pump performance necessary without producing excessive pump weight.

Field winding 88 generates a magnetic field to rotate rotor 46. Stator 80 is comprised of individual stator laminations 86 to eliminate eddy currents that generate heat and reduce efficiency. Heat flow from pump 10 is directed both into the blood stream and into the tissues surrounding pump 10. In this way, the blood is not heated in a manner that may damage the blood and, as well, the surrounding tissues do not have to absorb all the heat. Heat conductive flow paths using thermally conductive material, such as the metal of the stator or a thermally conductive gel, may be used to provide approximately the desired ratio of heat flow to the tissues compared to the heat flow to the blood.

As illustrated in FIG. 2, stator 80, comprised of individual laminations 86, is stacked in a presently preferred skewed manner such that pathways 90 provide a motor winding pathway that is offset from the rotor axis 92. The skew of laminations 86 may or may not correspond in some manner with the offset angle or changing offset angle of the row of magnets 82, and is not limited to the position shown in FIG. 2. A skewed stator 80 is also indicated in FIG. 2A, which shows an offset path from axis 92 for the field windings 88 which travel through stator 80. The skewing angle or offset from the rotor axis is used to optimize performance. The skewing angle of stator 80 may be variable rather than fixed along its length. While skewed stator 80 is the presently preferred embodiment, other factors or combinations of factors (e.g. small air gap, magnet orientation, etc.) produce excellent pump and motor performance without a skewed stator.

An axial force is produced on rotor 46 during rotation, which can be varied by moving stator 80 axially along pump housing 12. Stator 80 is axially adjustable for this purpose, and could be fixed in position during manufacturing for optimal performance given the number of magnets to be used and given other factors discussed hereinafter. The axial force thus produced can be used to offset the thrust created during pumping to reduce the load on the front or rear bearing assemblies 24 and 42, respectively. The axial positioning of stator 80 may also be used to optimize electrical motor efficiency.

Referring to FIG. 5, a block diagram of the control system 100 of the present invention is shown. Note that control system 100 may operate two motors 1 and 2, such as shown in FIG. 10. For some applications, either for implantation or for external use, it may be desirable to have two pumps connected either in parallel or in series. Thus, control system 100 can be easily configured for this purpose if desired. In addition, magnets (not shown) may be placed in the inducer hub to provide a secondary motor in the case of primary motor or controller failure. Various other back-up and redundancy configurations may be used.

For instance, in an axially spaced pump configuration shown in FIG. 10, motors 1 and 2 are axially-displaced from each other and may be operated separately or in conjunction with each other as control system 100 regulates power, as discussed herein-after, to axially spaced stators 207 and 208 containing stator windings 210 and 212, respectively. Ball-sOCKET bearing 203 on modified diffuser 204 rotatably supports rotor 205 of motor 2, which is axially spaced from rotor 206 of motor 1. Diffuser 204 acts as a flow straightener when independent operation of motor 2 is desired. Control system 100 may be used to operate both motors simultaneously or to turn one motor on if micro-controller 102 senses that another motor has failed. Micro-controller 102 may be programmed for pulsatile motor operation or continuous speed motor operation of one or more motors, as desired.

If only one pump is to be used, extra components may be removed. In FIG. 5, except for micro-controller 102, most components are duplicated to allow for operation of the two motors. For convenience, reference to corresponding components will be made to one number, with the corresponding component having an “a” suffix. Control system 100 operates either manually or by micro-controller 102, and is not limited to the position shown in FIG. 206. In FIG. 208, control system 100 may be easily configured for this purpose if desired.

Control system 100 applies current to stator windings 88. Preferably stator 80 includes three stator windings 88. Stator 80 generates a rotating magnetic field which magnets 82 and thus rotor 46 follow to produce motion. The motor stator may be three phase “Y” or “Delta” wound. The operation of the brushless D.C. motor of the present invention requires a proper sequence of power to be applied to stator windings 88. Two stator windings 88 have power applied to them at any one time. By sequencing the voltage on and off to the respective stator windings 88, a rotating magnetic field is produced.

A preferred embodiment three-phase motor requires a repetitive sequence of six states to generate a rotating magnetic field, although other commutation schemes could be used. The six states are produced by electronic commutation provided by power FET’s 104. If Motor 1 were sequenced through the six electrical states at a controlled frequency without feedback, its operation would be that of a stepper motor. In such a mode of operation, the motor rapidly loses its ability to generate torque as the rpm’s increase.

Control system 100 detects back electromotive force or back emf to control motor operation. Whenever a conductor, such as field winding 88, is cut by moving magnetic lines of force, such as are generated by magnets 82, a voltage is induced. The voltage will increase with rotor speed. It is possible to sense this voltage in one of the three stator windings 88 because only two of the motor’s windings are activated at any one time, to determine the rotor 46 position, and to activate commutator switches 104. The circuitry is much simpler and more reliable than Hall Effect sensors which have been used in the past. Although a back emf control is the presently preferred embodiment, a Hall effect driven commutation scheme could also be used.
Back emf integrated circuit 106 provides sensors for detecting the back emf from lines indicated at 107, and operates commutation switches 104 accordingly. A presently preferred back emf integrated circuit includes a ML4411 motor controller integrated circuit. Each commutation switch F.E.T. is preferably turned all the way on or off for maximum power efficiency.

Back emf integrated circuit 106 also provides a start up mode operation when the back emf is not present or large enough for detection. From zero to approximately 200 rpm's, motor 1 operates in stepper motor fashion as described hereinbefore. Motor speed is controlled with a difference amplifier 108, which may take its speed signal from either micro-controller 102 or speed adjust pot 110 as selected by switch 112. A speed detection signal is available from the back emf integrated circuit 106 for this purpose.

Restart circuit 110 and micro-controller 102 monitor voltage developed across sense resistor 111 (present preference is about 0.1 ohms) and the frequency signal from back emf integrated circuit 106 to determine whether motor 1 should be restarted, i.e., due to a sudden increase or decrease in current or frequency. Switch 113 may be used to select between use of restart circuit 110, micro-controller 102, or a manual restart switch 114. Controller 102 may be programmed to sense an alarm signal if there are sudden changes in power consumption or frequency, as may occur if heart strength weakens or improves. To protect the electronics from electromagnetic interference (EMI), ferrite beads 116 are used with wires to an external power supply. The electronics are preferably hermetically sealed in case 118, which is formed of a high mu material to limit EMI.

Referring now to preferred bearing configuration embodiments, FIG. 6A discloses a presently preferred ball-socket bearing configuration. The bearings are comprised of bio-compatible material and, in the presently preferred embodiment, are comprised of ceramic material. The ball-socket bearing 121 may be configured as shown in FIG. 1, or may be otherwise configured. Ball 120 is preferably secured by some securing means, such as glue or welding, along edge 128. Ball 120 could be molded into one component, or split and secured as is known in the art. Ball 120 has a spherical surface 122 that engages a mating seat spherical surface 124. A void or bearing chamber 126 is filled with a bio-compatible material to prevent blood from coming into this area and stagnating. In a preferred embodiment, bearing chamber 126 is left empty and allowed to fill with blood. The blood cross-links due to bearing heat and takes on a soft, pliable, plastic texture. The cross-linked blood may perform, to some extent, a bearing surface function. The cross-linked blood then prevents other blood from entering the bearing and stagnating.

While the ball-socket bearing is the preferred configuration, another configurations may be used. Shaft-journal bearing 130 provides shaft 132 secured to component 134, which may be rotor 46, for rotation with a second component 136, which may be diffuser 20. Journal sleeve 138 has a cylindrical bearing receiving surface 140 for engaging the cylindrical shaft bearing surface 142. A bio-compatible material in bearing chamber 144 is preferably cross-linked blood, as discussed hereinbefore, which has leaked into this chamber, been heated, and solidified. Another preferred embodiment of a shaft-journal bearing would include a shaft (not shown) extending through rotor 46 and engaging respective sleeves on flow straightener 18 and diffuser 20. As well, the flow straightener and/or diffuser, or relevant portions thereof, may be made from a suitable material, such as zirconia, with the bearing surfaces being formed or machined directly into that material. In a similar manner, the bearing surfaces of bearing 121, 130, or other bearings could be machined into a bearing mount component.

To avoid the problem of blood stagnation in the region of the bearings, several bearing washing configurations, using directed blood flow or pump differential pressures, may also be used as part of the present invention. Referring to FIG. 3, there is shown a means for using a pump pressure differential for washing bearing 150 which includes shaft 152 and journal sleeve 153. High pressure region 154 produces a blood flow through passage 156 to wash bearing 150 and exit to lower pressure region 158. Thus, blood is prevented from stagnating behind bearing 150.

Another bearing embodiment (not shown) would include a pressure fed journal bearing to form a hydrodynamic film that supports the shaft and loads so that the bearing surfaces do not touch. Shaft 152 would be slightly undersize with respect to a journal sleeve for this purpose. A pressure fed flow passage may be directed through such a hydrodynamic journal bearing from a high pressure region 154 to a low pressure region 158.

FIG. 6C illustrates another bearing washing method which includes a producing bend 160 in pump housing 12. This bend places bearing 162 in a high velocity flow area. Blood flow through bend 160 washes the bearing members, which include a male portion 164 and mating member 166. Other configurations for this type arrangement may be used, but the general principle is as described. The flow straightener is removed in this embodiment, but may be included in another embodiment, where it does not necessarily need to act as a bearing support.

FIG. 6D and 6E illustrate yet another bearing arrangement embodiment. In this embodiment, a bearing shaft 170 extends through journal sleeve 172. Bearing shaft 170 has an oblong or substantially oval transverse cross-section, as shown in FIG. 6E. This configuration produces flow paths 174 through journal sleeve 172 so as to flush the bearing and prevent blood stagnation. Shaft 170 could also be fluted so as to have spirals, slots, or other flow paths 174 formed along its periphery within sleeve 172.

FIG. 6F shows a bearing configuration wherein rotor 46 is cantilevered with respect to diffuser 20 using two bearings 180 and 182. Shaft 184 extends between the two bearings. Each bearing includes a rotating ball surface, 186 and 188, mating with a socket surface 190 and 192, respectively. Socket surfaces 190 and 192 are formed in ceramic material sleeves 194 and 196, respectively. The bearings are "zero tolerance" bearings. Thus, either the shaft 184 which runs through diffuser 20 or the diffuser 20 itself must provide a make-up mechanism that keeps each ball surface 186 and 188 tightly engaged with a respective socket 'surface' 190 and 192. For this purpose, diffuser 20 could be made of compressible material. Alternatively, diffuser 20 could receive injection molding around sleeves 194 or 196.

As another alternative, either a passive, active, or a combination passive-active magnetic bearing suspension system (not shown) could be used to rotatably mount rotor 46. For this embodiment, the rotor 46 would be axially positioned and/or bearing surfaces would be suspended with respect to each other using magnetic force.

The method of the present invention is illustrated in FIG. 8 which shows a test matrix for optimizing the pump parameters which are believed to affect hemolysis. This method enables optimization of pump parameters as discussed hereinafter with a minimum number of tests. Although this matrix is designed for a blood pump with no
13 inductor or flow straightener, it is believed that the method of the present invention is clearly illustrated with this example, and may be used to improve most other blood pump designs with respect to hemolysis, thrombus, pump efficiency, cost, and other important factors. Using this approach, it is possible to thoroughly investigate many parameters in an organized, methodical approach to achieve highly desired goals, such as optimum pump performance and minimum hemolysis.

To apply this method, it was first necessary to identify the pump parameters that were believed to affect hemolysis. The variables are listed at the headings of the test matrix, and include blade tip shape, radial clearance, axial clearance, number of blades, and impeller length. To judge effectively the impact of each variable on hemolysis, the method of the present invention requires that all pump dimensions be held constant while only one variable is changed. As shown in the matrix of FIG. 8, different tests are used. Preferably, each test is made at least three different times to provide statistical results and check consistency.

The information learned in initial tests is used later in the matrix. For example, tests 1 and 2 compare the effects of flat and round blade tip geometries. The least hemolytic of the two is then used in all remaining tests. If there is no statistically significant difference, then the result that provides superior hydrodynamic performance is used. If there is no hydrodynamic difference, then the least expensive parameter to manufacture is used. Test conditions are constant for each parameter. All tests were made using bovine blood at a flow of 5 liters/min against 100 mm Hg. The duration of each test was 20 minutes. The pump circulates blood through a test loop having a 500 cc blood reservoir which was conveniently a 500 cc blood bag. The 500 cc blood bag is preferably changed after each version of each parameter is tested.

In order to compare various impeller and stator blade geometries within a reasonable time period, a stereolithography technique was used to quickly realize the complex shapes. This technique relies on a laser beam that scans the surface of a liquid acrylic polymer. The polymer hardens under the influence of the laser, and layer by layer a solid shaped is formed from the liquid surface.

To compare hemolysis results, an index of hemolysis (IH) is used. This is defined as the amount of hemoglobin liberated in grams per 100 liters of blood pumped against 100 mm Hg. In equation form:

\[ IH = \Delta Hb \times V \times (1 - Ht) \times \frac{100}{(Flow \times Time)} \]  

where:
- \( IH \) equals amount of hemoglobin liberated in grams per 100 liters of blood pumped against 100 mm Hg;
- \( Ht \) is the hematocrit in decimal percent;
- \( V \) is the blood volume in liters;
- \( \Delta Hb \) is the amount of hemoglobin liberated in a fixed time period in grams/liter;
- Flow is the flow rate in liters per minute; and
- Time is the total time in minutes at that flow rate.

The final results are seen in the matrix of FIG. 8. Other more detailed factors of testing in accord with the method of this invention are discussed more thoroughly in the articles by reference. 65

As to manufacturing and usage considerations, pump 10 is preferably manufactured using materials designed to be buoyant inside the body to make the completed pump neutrally buoyant or approximately neutrally buoyant. This minimizes stress on stitches or other means used to position the pump within the body. Thus, the rotor, rotor blades, and/or other components may be made with a lightweight material having sufficient thickness to produce a buoyant effect.

Pump 10 has numerous uses as a blood pump, including use as a portable blood pumping unit for field service. Pump 10 may also be used for other clinical applications involving other fluids. It could, for instance, be used in a compact heartlung machine. Due to the small volume and size of pump 10, it can be placed close to a patient to minimize shock caused when initiating blood pump operation using a saline solution. Larger pumps, with larger volume, may be awkward to move close by a patient to eliminate this shock.

The blood pump of the present invention, particularly when optimized using the method of the present invention, has many advantages over the prior art. For instance, there are no blood seals which require bearing purge systems. No Hall Effect sensors are required which may tend to limit motor control reliability due to their complexity. As well, pump 10 provides low power consumption and very low levels of hemolysis.

The foregoing disclosure and description of the invention is illustrative and explanatory thereof. It will be appreciated by those skilled in the art that various changes in the size, shape, materials, as well as in the details of the illustrated construction, may be made without departing from the spirit of the invention.

What is claimed is:

1. A blood pump, comprising:
   - a pump housing having a blood flow path therethrough;
   - a first stator mounted to said pump housing, said first stator having a first stator field winding for producing a first stator magnetic field;
   - a first rotor mounted within said pump housing for rotation about a longitudinal axis of said first rotor in response to said first stator magnetic field, said first rotor carrying a blade thereon for propelling blood through said pump housing along said blood flow path, at least a portion of said blade being affixed to said rotor at an angle that is offset with respect to said longitudinal axis;
   - a plurality of magnets secured to said at least a portion of said blade affixed to said rotor at an angle that is offset with respect to said longitudinal axis, said plurality of magnets producing a first rotor magnetic field that passes through said first stator field winding during said rotation of said first rotor to induce a back emf within said first stator field winding; and
   - back emf sensor circuitry connecting to said first stator field winding to sense said back emf produced during said rotation of said first rotor within said pump housing.

2. The pump of claim 1, wherein said first stator further comprises:
   - a plurality of laminations, said plurality of laminations defining therein a pathway substantially conforming to an outer wall of said pump housing, said field winding of said first stator being disposed within said pathway, at least a portion of said field winding and said pathway being skewed with respect to said longitudinal axis of said first rotor.

3. The pump of claim 2, further comprising:
   - a first back emf controller integrated circuit electrically connected to a portion of said back emf sensor circuitry
and including a sense resistor in series with said first stator field winding, said first back emf controller integrated circuit operable for controlling rotation of said first rotor by said first stator winding;

a restart circuit electrically connected to said sense resistor to restart operation of said back emf controller integrated circuit upon sensing a change in operation of said first rotor.

4. The pump of claim 2, further comprising:

a second rotor within said pump housing axially spaced from said first rotor;

a second stator field winding axially displaced from said first stator field;

a second back emf controller integrated circuit for controlling rotation of said second rotor by means of said second stator field winding; and

a micro-controller electrically connecting to said first and second back emf controllers for operating said first and second rotors, respectively, through said first and second back emf controller integrated circuits.

5. The pump of claim 1, further comprising:

a micro-controller for monitoring power required for rotating said first rotor, said micro-controller being electrically connected to said sense resistor, said micro-controller being programmable; and

for providing an alarm signal in response to an unexpected increase or decrease in said power required for rotating said first rotor.

6. The pump of claim 1, further comprising:

said back emf sensor circuitry having a sense resistor in series with said first stator winding; and

a micro-controller electrically connected to said sense resistor for monitoring frequency of rotation of said first rotor, said microcontroller being programmable for providing an alarm signal in response to an unexpected increase or decrease in said frequency of rotation of said first rotor.

7. The pump of claim 1, further comprising:

said first stator and said plurality of permanent magnets having a radial spacing therebetween of from 0.01 inches to 0.025 inches.

8. The pump of claim 1, further comprising:

a blood flow straightener fixably secured within said pump housing and adjacent an entry portion of said blood flow path, said flow straightener having a plurality of fixed blades each extending radially inwardly from an inner wall of said blood flow path towards a central portion of said blood flow path for axially directing blood flow before said blood flow encounters said first rotor.

9. The pump of claim 8, wherein said blood flow straightener further comprises:

a hub member centrally disposed within said blood flow path and secured to each of said fixed blades, said hub member supporting a front bearing for said first rotor.

10. The pump of claim 8, wherein:

each of said plurality of fixed blades has a sloping initial edge.

11. A blood pump, comprising:

a pump housing having a blood flow path therethrough;

a stator disposed about a portion said pump housing and having a stator field winding for producing a stator magnetic field;

a rotor mounted within said pump housing for rotation in response to said stator magnetic field;

a plurality of impeller blades secured to said rotor and extending radially outwardly from said rotor, said plurality of impeller blades being operable for propelling blood along said blood flow path through said pump housing; and

at least one magnet implanted in each of said plurality of impeller blades adjacent a radially peripheral edge of a respective impeller blade, said at least one magnet being responsive to said stator magnetic field for producing rotational movement of said rotor.

12. The pump of claim 11, further comprising:

said at least one magnet includes a plurality of magnets implanted in each of said impeller blades adjacent said radially peripheral edge of a respective impeller blade.

13. The pump of claim 12, wherein:

at least a portion of each of said impeller blades and at least a portion of said corresponding plurality of magnets implanted in each of said impeller blades being affixed to said rotor at a first angle which is offset with respect to a longitudinal axis of said rotor.

14. The pump of claim 11, wherein:

said stator field winding for producing said stator magnetic field is skewed at an angle with respect to a longitudinal axis of said rotor.

15. The pump of claim 11, wherein:

said stator is axially movable with respect to said pump housing for selectively providing an approximate predetermined axial force on said rotor to offset an opposing created force due to pumping by said impeller blades.

16. The pump of claim 11, further comprising:

thermal flow paths adjacent said stator operative to direct a portion of heat generated in said stator to tissues around said stator, the remaining portion of said heat being directed to blood flowing through said pump.

17. The pump of claim 11, wherein:

said stator and said at least one magnet implanted in each of said impeller blades define a radial spacing therebetween of from 0.01 inches to 0.025 inches.

18. A blood pump, comprising:

a pump housing having a blood flow path therethrough;

a stator mounted to said pump housing, said stator having a stator field winding for producing a stator magnetic field;

a rotor mounted within said pump housing for rotation in response to said stator magnetic field;

an inducer portion of said rotor having a plurality of inducer blades equidistantly disposed about a circumference of said rotor, each of said plurality of inducer blades having a pitch which varies along their axial length;

an impeller portion of said rotor, said impeller portion being axially adjacent said inducer portion of said rotor, said impeller portion of said rotor having a plurality of impeller blades equidistantly disposed about said circumference of said rotor; and

at least one interconnecting blade segment which interconnects between at least one of said inducer blades and at least one of said impeller blades to form a single continuous blade through said inducer portion and said impeller portion of said rotor.

19. The blood pump of claim 18, wherein:

said plurality of impeller blades equidistantly disposed about said circumference of said rotor include alternating axially longer impeller blades and axially shorter impeller blades.
20. The blood pump of claim 19, further comprising: said at least one interconnecting blade segment connecting each of said axially longer impeller blades and a corresponding inducer blade to define a plurality of continuous blades extending through said inducer portion and said impeller portion.

21. The blood pump of claim 18, wherein:
each of said plurality of inducer blades has a wrap of from approximately 25° to 45° with a midpoint angle of from approximately 25° to 45°.

22. The blood pump of claim 18, wherein:
each of said plurality of inducer blades has an entrance angle of from about 10° to 20° and an outlet angle of from approximately 10° to 25° with a midpoint angle of from approximately 25° to 45°.

23. The blood pump of claim 18, wherein:
each of said plurality of inducer blades has a wrap of from about 200° to 300°; and each of said plurality of inducer blades overlaps an adjacent inducer blades by from about 100° to 200°.

24. The blood pump of claim 18, further comprising:
an inner wall of said pump housing, said inner wall of said pump housing and a radially outwardly edge of at least one of said blades disposed on said rotor defining a radial clearance between said inner wall and said radially outwardly edge of from about 0.003” to 0.015”.

25. The blood pump of claim 18, further comprising:
a hub portion of said rotor, said hub portion having a hub diameter with a hub ratio of from about 0.45 to 0.55 defined by dividing said hub diameter by an outer diameter of a circle circumscribed about said plurality of blades.

26. The blood pump of claim 18, wherein:
each of said inducer blades has a variable pitch with an inlet angle of from about 10° to 25° and an outlet angle of from about 80° to 90°.

27. The blood pump of claim 18, further comprising:
a flow straightener adjacent an entrance of said blood flow path, said flow straightener having a plurality of flow straightener blades disposed about a hub portion of said rotor, said plurality of flow straightener blades having an entrance angle and an exit angle of from about 80° to 90°.

28. The blood pump of claim 27, wherein:
said flow straightener has from 2 to 4 blades.

29. The blood pump of claim 27, wherein:
said flow straightener is axially spaced from said inducer portion by from about 0.010 inches to 0.50 inches.

30. The blood pump of claim 18, further comprising:
a diffuser axially spaced from said impeller portion and affixed to said pump housing adjacent an exit portion of said blood flow path from said pump housing, said diffuser having a plurality of diffuser blades each having an entrance angle of from about 10° to 25° and an exit angle of from about 80° to 90°.

31. The blood pump of claim 30, further comprising:
a tail cone having a substantially hyperbolic contoured portion for reducing turbulence at an outlet of said blood pump.

32. The blood pump of claim 31, wherein:
said diffuser is axially spaced from said impeller portion by from about 0.010 inches to 0.050 inches and has from 5 to 8 blades, said diffuser forming a bearing support for said rotor.

33. The blood pump of claim 18, wherein:
said inducer portion has from 2 to 6 inducer blades and said impeller portion has from 2 to 6 impeller blades.

34. A method of manufacturing a rotary blood pump, comprising the following steps:
providing a tubular metallic rotary pump housing;
providing a rotor in said housing;
providing a bearing for said rotor within said housing and damping said rotor in position in said tubular metallic rotary pump housing with a damp external to said tubular metallic rotary pump housing to deform said tubular metallic rotary pump housing in the locus of said bearing.

35. The method of claim 34, further comprising:
providing a plastic rotor bearing support; and reinforcing said plastic rotor bearing support to prevent plastic deformation.

36. The method of claim 34, further comprising:
providing an electronic control package for controlling said rotor;
hermetically sealing said electronic control package in a high mu case to limit electromagnetic interference; and providing ferrite beads on battery leads into said electronic control package.

37. The method of claim 34, further comprising:
providing a bend in said metallic rotary pump housing in the locus of said bearing for flushing said bearing.

38. The method of claim 34, further comprising:
providing a passageway from a high pressure portion of said pump to a bearing in a low pressure portion of said pump.

39. The method of claim 34, further comprising:
providing a passageway from a high pressure portion of said pump to a bearing in a low pressure portion of said pump.

40. The method of claim 34, further comprising:
adjusting the weight of said pump with a buoyant material.

41. The method of claim 34, further comprising:
limiting a number of permanent magnets disposed in an impeller portion of said rotor to only that number necessary to provide a desired drive force of said rotor so as to limit inertia forces on said impeller portion.

42. A rotary blood pump, comprising:
a pump housing having a blood flow path therethrough; a stator mounted to said pump housing, said stator having a stator field winding for producing a stator magnetic field;
a rotor mounted within said pump housing for rotation in response to said stator magnetic field;
a first rotor bearing for rotatably supporting said rotor within said pump housing, said first rotor bearing including a fixed bearing surface substantially fixed with respect to said housing, said fixed bearing surface receiving a rotating bearing surface that rotates with said rotor, said fixed bearing surface and said rotating bearing surface defining a bearing engagement region therebetween, said bearing engagement region fluidly separating said blood flow path from a dosed bearing chamber adjacent said bearing engagement region, said dosed bearing chamber being sealed from said fluid flow path except along said bearing engagement region, said bearing chamber being filled with bio-compatible material to prevent blood flow from said blood flow.
19. path into said dosed chamber from between said fixed bearing surface and said rotating bearing surface.

43. The pump of claim 42, wherein:
said bio-compatible material is cross-linked blood.

44. The pump of claim 42, wherein:
said fixed beating surface and said rotating bearing surface each have a mating spherical portion.

45. The pump of claim 42, further comprising:
a second rotor bearing on an opposite side of said rotor from the first rotor bearing, said second rotor bearing having a cylindrical curved bearing surface for receiving a cylindrical shaft.

46. The pump of claim 42, further comprising:
a second rotor bearing on an opposite side of said rotor from said first rotor bearing; and
means for flushing said second rotor bearing.

47. The pump of claim 42, wherein:
said fixed beating surface and said rotating bearing surface are each cylindrical surfaces.

48. The pump of claim 45, further comprising:
said second rotor bearing including a sleeve with a cylindrical internal bearing surface and a shaft received therein, said shaft having a flow passage at its periphery to allow blood flow along said cylindrical internal bearing surface.

49. The pump of claim 42, further comprising:
an additional fixed bearing surface which engages said rotating member formed from said bio-compatible material in said bearing chamber.
UNlTED STATES PATENT AND TRADEMARK OFFICE
CERTIFICATE OF CORRECTION

PATENT NO. : 5,527,159
DATED : Jun. 18, 1996
INVENTOR(S) : Richard J. Bozeman, Jr., et al.

It is certified that error appears in the above-identified patent and that said Letters Patent is hereby corrected as shown below:

Column 15, line 41, “sparing” should read __spacing__.
Column 18, line 6, “damping” should read __clamping__.
Column 18, line 7, “damp” should read __clamp__.
Column 18, line 46, “homing” should read __housing__.
Column 18, line 57, “beating” should read __bearing__.
Column 18, line 59, “dosed” should read __closed__.
Column 18, line 60, “beating” should read __bearing__.
Column 18, line 61, “dosed beating” should read __closed bearing__.
Column 18, line 62, “beating” should read __bearing__.
Column 18, line 63, “beating” should read __bearing__.
Column 19, line 1, “dosed” should read __closed__.
Column 19, line 6, “beating” should read __bearing__.
Column 20, line 2, “beating” should read __bearing__.

Signed and Sealed this
Twenty-first Day of September, 1999
