1. Abstract

Performance Seeking Control (PSC) attempts to find and control a process at an operating condition that will generate maximum performance. In this paper a nonlinear multivariable PSC methodology will be developed, utilizing the Fuzzy Model Reference Learning Control (FMRLC) and the method of Steepest Descent or Gradient (SDG). This PSC methodology employs the SDG method to find the operating condition that will generate maximum performance. This operating condition is in turn passed to the FMRLC controller as a set point for the control of the process. The conventional SDG algorithm is modified in this paper in order for convergence to occur monotonically. For the FMRLC control, the conventional fuzzy model reference learning control methodology is utilized, with guidelines generated here for effective tuning of the FMRLC controller.

2. Introduction

PSC approaches, primarily developed for aircraft applications, are largely based on dynamic or linear programming with some limited work having been performed on gradient-type PSC. Even though random-type search techniques for PSC (like linear or dynamic programming) have proven effective for various applications, a number of difficulties can be encountered in the implementation of these techniques such as poor convergence or long execution times.

In this paper, the combined effect of gradient optimization and FMRLC control with its ability to perform nonlinear control, with fast on-line learning of the control law, will be exploited. The state trajectory that generates maximum performance resulting from the SDG algorithm, is passed to the FMRLC controller as the desired set point for the control of the process, Fig. 1. The computed control trajectory can also be utilized by the FMRLC, if it is desired to use the FMRLC as a trim controller.

The standard SDG control algorithm can fail to converge if the initial guess of the control inputs is rather poor. Therefore the algorithm is modified here in order for convergence to occur monotonically, which makes the algorithm more suitable for on-line implementation.

During the past several years, fuzzy control has emerged as one of the most active and promising control areas, especially because of the ability of fuzzy control in controlling highly nonlinear, time variant, and ill-defined systems. The works of Mamdani and his colleagues on fuzzy control (11-14) was motivated by Zadeh's work on the theory of fuzzy sets, (16-19) and its application to linguistics and systems analysis. The work of Procyk and Mamdami on the linguistic self-organizing controller (20) as well as refinements to this algorithm made by others, was later modified and extended by Layne to what it is called FMRLC control. (21) The FMRLC structure, Fig. 4, has learning capabilities and differs conceptually from adaptive control primarily by its ability to memorize learned experiences. The FMRLC algorithm will be utilized here for nonlinear, multivariable feedback control, while some guidelines will be generated for the effective tuning of the FMRLC controller. In this paper the SDG and FMRLC controllers will be combined to form the new PSC control structure shown in Fig. 1.

It is assumed here that the model of the plant is available. However, a standard Kalman-filter estimator, or some other identification technique, could be used to
identify the plant on-line if necessary\(^{(8,9)}\). The implied assumption here is made that the solution space is convex, in order for the SDG control to find the global extremal within the constraints of the control inputs.

A nonlinear process is selected to demonstrate the effectiveness of this control methodology. The process in (1) is chosen to be nonlinear, stable, with significant cross coupling of the control inputs to the controlled variables.

\[
\begin{align*}
\dot{x}_1 &= -2x_1x_2 + 3x_2 + u_1 \\
\dot{x}_2 &= x_1^2 - x_2^3 + u_2
\end{align*}
\]  

(1)

The process itself (i.e. with zero control input) is determined to be stable by using the Liapunov Direct method, with the Liapunov function: \(V(x_1,x_2) = a x_1^m + b x_2^n\). With the choices of \(m = 1, n = 1, a = 1, b = 2\), which simplifies \(V(x), V(x_1,x_2) = x_1^2 + 2x_2^2\), which is positive definite. \(\dot{V}(x) = \nabla V(x(t))^T f(\dot{x}(t)), \) with no control input, \(\dot{V}(x_1,x_2) = -4x_1^4 + 6x_1x_3\) which is negative semidefinite as long as the inequality \(2x_2 \geq 3x_1\) is satisfied.

In section 3, the formulation of SDG optimization for the process in Eq. (1) and the performance index in Eq. (2) will be carried out. In section 4 the FMRLC control methodology will be discussed and the multivariable control design for the process in Eq. (1) will be shown. Section 5 will cover the conclusion.

### 3.1 Steepest Descent Gradient Formulation

Generally a performance index and the plant states can be expressed as:

\[
J = h(x(t_f), t_f) + \int_{t_0}^{t_f} g(x(t), u(t), t) \, dt
\]  

(2)

The performance index selected for this problem has the form

\[
J[x(t), t_f] = \int_0^{t_f} \left[ \dot{x}(t)^T Q \dot{x}(t) + u(t)^T R u(t) \right] \, dt
\]  

(4)

where: \(\dot{x} = [(x_1 - x_{10})(x_2 - x_{20})]^T, u = [u_1 u_2]^T,\)

\[
Q = \begin{bmatrix} 1 & 0 \\ 0 & 0.5 \end{bmatrix}, \quad \text{and} \quad R = \begin{bmatrix} 0.5 & 0 \\ 0 & 0.5 \end{bmatrix}
\]

and \(x_{10}, x_{20}\) are constants.

For the case where \(h(x(t_f), t_f) = 0\) in (2), the hamiltonian of the system in Eq. (3) with the performance index (2) can be expressed as:

\[
H(x(t), u(t), p(t)) = g(x(t), u(t), t) + p(t)[a(x(t), u(t), t)]
\]  

(5)

where \(p(t)\) are the costate equations. Substituting into Eq. (5) the functions \(g\) and \(a\) from Eqs. (2) and (3) relative to the plant in Eq. (1) and the performance index in Eq. (4),

\[
H = (x_1 - x_{10})^2 + (x_2 - x_{20})^2 + 0.5u_1^2 + 0.5u_2^2
\]

\[
+ p_1(-2x_1x_2 + 3x_2 + u_1) + p_2(x_2^2 - x_3^2 + u_2)
\]

(6)

The costate equations are:

\[
\dot{p}_1 = -\frac{\partial H}{\partial x_1} = -2(x_1 - x_{10}) + 2p_1x_2 - 2p_2x_1
\]

(7)

\[
\dot{p}_2 = -\frac{\partial H}{\partial x_2} = -2(x_2 - x_{20}) + p_1(2x_1 - 3) + 3p_2x_2^2
\]

The partials of the hamiltonian with respect to the controls are:

\[
\frac{\partial H}{\partial u_1} = u_1 + p_1
\]

(8)

\[
\frac{\partial H}{\partial u_2} = u_2 + p_2
\]

The control history \(u^{01}(t), t \in [t_0, t_f]\) is used to solve the differential equations in (3) and (7) (including the
superscripts $x^{(i)}, u^{(i)}, p^{(i)}$ in (3) and (7), and (i) is an index signifying the current iteration), so that the nominal state-costate trajectory satisfies the boundary conditions:

$$x^{(i)}(t_0) = x_0$$

and

$$p^{(i)}(t_f) = \frac{\partial H}{\partial x}(x^{(i)}(t_f))$$

(9)

The initial conditions in (9) are split boundary, and the differential equation in (3) is solved forward in time, where Eq. (7) is solved backwards in time. Since $h(x(tf), tf) = 0$ in Eq. (2), $p^{(i)}(tf) = 0$. If this nominal control history also satisfies

$$\frac{\partial H}{\partial u}(x^{(i)}(t), u^{(i)}(t), p^{(i)}(t), t) = 0, \quad t \in [t_0, tf]$$

(10)

which is equal to Eq. (8) for this problem, then $u^{(i)}, x^{(i)}, p^{(i)}$ are extremals. If Eq. (10) is not satisfied, successive control histories are adjusted as follows:

$$u^{(i+1)}(t_k) = u^{(i)}(t_k) - \tau \frac{\partial H^{(i)}}{\partial u}(t_k) \quad k = 0, ..., N-1$$

(11)

where, $\tau > 0$, is selected for the desired effect $\partial H/\partial u$. Eq. (8) will have on the new control, and $t_k$ signifies a discrete time. Note that the elements of Eq. (11) signify vector quantities for a multivariable control process. The iterative computation process is terminated when norm two,

$$\left\| \frac{\partial H}{\partial u} \right\|_2 = \sqrt{\int_{t_0}^{t_f} \left[ \frac{\partial H}{\partial u}(t) \right]^2 dt}$$

at iteration (i) is less than a preselected positive termination constant $\gamma_1$, or the performance index $J^{(i)} - J^{(i-1)} \leq \gamma_2$. The basic SDG algorithm listed below has been modified as to achieve monotonic convergence.

SDG Algorithm Steps:

1. Select a discrete piecewise-constant approximation to the nominal control history $u^{(0)}(t), t \in [t_0, tf]$.
2. Using the nominal control history $u^{(i)}$, integrate the state equations from $t_0$ to $t_f$ with initial conditions $x(t_0) = x_0$ and store the resulting trajectory.
3. Integrate the costate equations backwards in time from $t_f$ to $t_0$ using $p(t_f) = p_f$ as the initial condition and the piecewise-constant values of $x^{(i)}$. At each time step evaluate $\partial H^{(i)}/\partial u, t \in [t_0, tf]$ and store in the computer.

The following steps from 3.1 to 3.2 constitute changes to the SDG algorithm to achieve monotonic convergence:

3.1 Evaluate the performance index $J(i)$. If $J^{(i)} > J^{(i-1)}$ restore the previous control trajectory (i.e. set $u^{(i)}(t) = u^{(i-1)}(t), t \in [t_0, tf]$) and repeat step 2 and 3 from above.

3.2 Find the component of $\| \frac{\partial H^{(i)}}{\partial u} \|_2$ with the largest magnitude and decrease its corresponding $\tau$ component (halving $\tau$ is found to work fine for various problems).

4. If $\| \frac{\partial H^{(i)}}{\partial u} \|_2 < \gamma_1$ or $|J^{(i)} - J^{(i-1)}| < \gamma_2$ then terminate the iterative procedure and output the extremal states and control. If the stopping criterion is not satisfied, keep in storage the previous control vector (this step is added relative to changes for monotonic convergence), and generate a new piecewise-constant control history given by Eq. (11). Return to step 2.

3.2 Steepest Descent Gradient Simulation

The final time, $t_f$, in Eq. (4) can be chosen appropriately based on the settling time of the process to a step input, Fig. 2. The fourth order Runge-Kutta integration method was used for forward and backwards integration of Eqs. (1) and (7) respectively. Euler integration was also used as an alternative, but no noticeable differences in the simulation results were observed for this problem. Choosing rather large $\gamma$'s in Eq. (11), would normally cause the steepest descent algorithm to diverge or fail to converge. However, the modifications made to the algorithm in this paper will cause the algorithm to monotonically converge, because $\tau$ is adjusted automatically. Figure 3 shows the monotonically decreasing performance index, the state trajectories for the choice of $(x_{10}, x_{20}) = (1.3, 1.2)$, and the resulting control trajectories.

4.1 Fuzzy Model Reference Learning Control

Fuzzy control theory will not be covered in depth in this paper. For more detail discussions in these areas see Refs. 11 to 22. The FMRLC structure, shown in Fig. 4, employs an inverse fuzzy model of the process and modifies the knowledge base through the knowledge base modifier mechanism in order for the process output $y(kt)$ to match the reference model output $y_m(kt)$. In this section the basic design procedure of the FMRLC for the process in Eq. (1) will be discussed.

For the MIMO system discussed in this paper two decoupled FMRLC controllers are constructed. A coupled FMRLC controller could be utilized instead, however, the
dimensions of the knowledge bases would have increased equivalent to the number of the inputs to the fuzzy controller. In addition to the basic FMRLC structure shown in Fig. 4, a pole at zero frequency was placed at the output of each decoupled controller. This is needed for zero steady state error. Each decoupled FMRLC controller contains 6 adjustable gains. Therefore, some discussion in this section will be devoted to establishing some guidelines for the effective tuning of the control gains. Typical inputs to the fuzzy controller are the error $e(kT)$ and the error derivative $c(kT)$, but other types of inputs can be chosen such as integration of the error. The membership functions for all the inputs to the fuzzy controllers and the inverse models have been chosen with triangular shape, normalized, and uniformly distributed in each Universe of Discourse, as shown in Fig. 5. In Fig. 5, $E_j$ signifies a membership function or linguistic value associated with a specific input to the fuzzy controller, where $\mu$ gives the certainty that an element of that particular input may be classified heuristically as $E_j$. Figure 6 shows the rule base constructed for the inverse fuzzy models. From this rule base it can be deduced that the Consequent membership functions corresponding to the inverse model output variable $y_j(kT)$ have similar distribution to the membership functions shown in Fig. 5. The knowledge base (rule base) contains the centers of the membership functions which are triangular shaped for this problem, with a base width of 0.4 as seen in Fig. 5.

Figure 4.—FMRLC structure.

Figure 5.—Membership functions.

Figure 6.—Inverse fuzzy model rule base.
One of the important considerations in the construction of the inverse knowledge base is that the inverse fuzzy model exhibits the proper directionality associated with the controlled process. The knowledge base associated with the fuzzy controllers initially contains all zeros, which reflects no knowledge of how to control the process. This knowledge base is updated automatically as the FMRLC controller learns how to control the process.

The selection of the FMRLC gains is an important step in the design process, as the ability of the controller to track the reference model will heavily depend on the particular choices of the gains. The gains $g_e$ and $g_y$ are chosen so that the ranges of these inputs are mapped to a normalized universe of discourse in the range of [-1,1]. For instance an appropriate choice for the value of the gain $g_e$ would be $1\cdot \text{range} (e(kt))$. A good choice for the value of the gain $g_e$ is found to be approximately equal to $10\cdot \text{range} (e(kt))$, which is equal to $10\cdot \text{max change} (r(kt))/T$, where $r(kt)$ is the set point and $T$ is the sampling time. The smaller the choice for the values of the gains $g_e$ and $g_y$, the more the control action is concentrated towards the center region of the rule base, resulting in better control tracking at the expense of an increased control rate of the control variable $u(kT)$. The gain, $g_y$, effects the damping of the process response: If it’s too small the response will be oscillatory, if it’s too large, the process will be unable to keep up with the reference model. A good choice for the value of the gain, $g_y$, is found to lie somewhere in the range of $[1/(4\omega_n), \sqrt{2}(2\omega_n)]$, where $\omega_n$ is the natural frequency of the process. The output gains, $g_u$ and $g_p$ are chosen so that the corresponding Normalized Universe of Discourse maps to the range of the output variables of the fuzzy controller. For instance, both $g_u$ and $g_p$ are selected to be equal to the range of the output input variable, $u(kT)$. This choice for the output gains allows both $u(kT)$ and $y_f(kT)$ to take on values as large as the largest control input.

The selection of the reference model shown in Fig. 4, represents the desired performance of the FMRLC feedback control system. The reference model is selected here to have a natural frequency, $\omega_m$, equal to the process natural frequency, $\omega_n$, with a relatively low step value for the open loop response. With the process being nonlinear, its response time can strongly depend on the magnitude of the control input. Therefore, it may not be desirable to select a reference model significantly faster than the process response time relative to a low control input value, or else we may be asking for relatively large control rates.

A first order model for the selection of the reference model has been found to be adequate.

$$G_{RM} = \frac{\omega_m}{s + \omega_m} \quad (12)$$

4.2 FMRLC Control Simulation

Based on the discussion in section 4.1, the control parameters for the two decoupled FMRLC controllers have been selected with the following values:

$$\begin{bmatrix}
    g_{e1} & g_{y1} & g_{e2} & g_{y2} & g_{u1} & g_{f1} & \omega_{m1} \\
    g_{e1} & g_{y1} & g_{e2} & g_{y2} & g_{u2} & g_{f2} & \omega_{m2}
\end{bmatrix} = \begin{bmatrix}
    0.25 & 0.25 & 0.1 & 0.125 & 10 & 10 & 2 \\
    0.25 & 0.25 & 0.1 & 0.125 & 10 & 10 & 2
\end{bmatrix}$$

The defuzzification approach used in this simulation is the so called “Center of Gravity.” Figure 7 shows the response of the decoupled FMRLC controller with simultaneous step set point changes. This response shows the tracking capabilities of the FMRLC. The set point tracking response was used to tune the controller as was discussed in section 4.1. The knowledge base of the fuzzy

![Figure 7.—FMRLC close loop step response.](image-url)
controller started with all zero entries, reflecting that initially there was no knowledge of how to control the system. The learning rate is quite fast as is evident from the responses of the states and control inputs in Fig. 7. The resulting knowledge base of the decoupled controller corresponding to the state $x_2$, for the simulation in Fig. 7, is shown in Fig. 8. The zero elements associated with this knowledge base is an indication that the controller, for this particular simulation, has not had the opportunity to venture in these areas of its knowledge space.

For a complete simulation of the PSC approach discussed in this paper, in section 3 with the SDG formulation and the modified SDG algorithm, the optimal state and control trajectories were found, Fig. 3. The states trajectories are passed to the FMRLC controller as the desired set point control for the control of the process in Eq. (1), shown in Fig. 9. In the simulation (Fig. 10), the control trajectories were also utilized by adding them to the control output of each decoupled FMRLC controller as you would for a trim control structure. Due to memory limitations for the PC Fortran used in this simulation, the state and control trajectories of Fig. 3 were approximated by first order responses, which would be expected to introduce error in the trim control. All the control parameters discussed in this section remained the same for the simulations shown in Figs. 9 and 10, except for the reference model frequency, $\omega_m$, which was increased to 16 rad/sec. For these simulations, the knowledge bases of the two decoupled controllers were also initialized with zeros, but the resulting knowledge bases from the simulation in Fig. 7 could have been used as the starting point.

5.0 Conclusion

In this paper a nonlinear process was used to help develop a PSC methodology that utilized the modified SDG and FMRLC approaches. The simulation results presented in this paper showed that the modified SDG algorithm can be used effectively to compute off-line the optimal state and control trajectories for the control process. The results also showed that the FMRLC approach with the given tuning guidelines, can be used to control the nonlinear multivariable control process with good tracking performance, and relatively fast on-line learning of the control law. Finally, the optimal states and control trajectories computed by the SDG algorithm are utilized in this paper by the FMRLC to control the process to achieve the desired performance.

For future work it would be important to study stability, convergence, and robustness of this approach in more detail. Further, experimental validation of this method would be needed, with processes that exhibit more complex dynamics. Finally, a direct comparison with other existing PSC control methodologies could be carried out.

Performance Seeking Control (PSC) attempts to find and control the process at the operating condition that will generate maximum performance. In this paper a nonlinear multivariable PSC methodology will be developed, utilizing the Fuzzy Model Reference Learning Control (FMRLC) and the method of Steepest Descent or Gradient (SDG). This PSC control methodology employs the SDG method to find the operating condition that will generate maximum performance. This operating condition is in turn passed to the FMRLC controller as a set point for the control of the process. The conventional SDG algorithm is modified in this paper in order for convergence to occur monotonically. For the FMRLC control, the conventional fuzzy model reference learning control methodology is utilized, with guidelines generated here for effective tuning of the FMRLC controller.
