Since its founding, NASA has been dedicated to the advancement of aeronautics and space science. The NASA Scientific and Technical Information (STI) Program Office plays a key part in helping NASA maintain this important role.

The NASA STI Program Office is operated by Langley Research Center, the lead center for NASA's scientific and technical information. The NASA STI Program Office provides access to the NASA STI Database, the largest collection of aeronautical and space science STI in the world. The Program Office is also NASA's institutional mechanism for disseminating the results of its research and development activities. These results are published by NASA in the NASA STI Report Series, which includes the following report types:

- **TECHNICAL PUBLICATION.** Reports of completed research or a major significant phase of research that present the results of NASA programs and include extensive data or theoretical analysis. Includes compilations of significant scientific and technical data and information deemed to be of continuing reference value. NASA counter-part of peer reviewed formal professional papers, but having less stringent limitations on manuscript length and extent of graphic presentations.

- **TECHNICAL MEMORANDUM.** Scientific and technical findings that are preliminary or of specialized interest, e.g., quick release reports, working papers, and bibliographies that contain minimal annotation. Does not contain extensive analysis.

- **CONTRACTOR REPORT.** Scientific and technical findings by NASA-sponsored contractors and grantees.

- **CONFERENCE PUBLICATION.** Collected papers from scientific and technical conferences, symposia, seminars, or other meetings sponsored or co-sponsored by NASA.

- **SPECIAL PUBLICATION.** Scientific, technical, or historical information from NASA programs, projects, and missions, often concerned with subjects having substantial public interest.

- **TECHNICAL TRANSLATION.** English-language translations of foreign scientific and technical material pertinent to NASA's mission.

Specialized services that help round out the STI Program Office's diverse offerings include creating custom thesauri, building customized databases, organizing and publishing research results ... even providing videos.

For more information about the NASA STI Program Office, you can:

- E-mail your question via the Internet to help@sti.nasa.gov
- Fax your question to the NASA Access Help Desk at (301) 621-0134
- Phone the NASA Access Help Desk at (301) 621-0390
- Write to: NASA Access Help Desk NASA Center for AeroSpace Information 800 Elkridge Landing Road Linthicum Heights, MD 21090-2934

Abstract

A hybrid Finite Element Method (FEM)/Method of Moments (MoM) technique in conjunction with the Asymptotic Waveform Evaluation (AWE) technique is applied to obtain radar cross section (RCS) of a cavity-backed aperture in an infinite ground plane over a frequency range. The hybrid FEM/MoM technique when applied to the cavity-backed aperture results in an integro-differential equation with electric field as the unknown variable, the electric field obtained from the solution of the integro-differential equation is expanded in Taylor series. The coefficients of the Taylor series are obtained using the frequency derivatives of the integro-differential equation formed by the hybrid FEM/MoM technique. The series is then matched via the Padé approximation to a rational polynomial, which can be used to extrapolate the electric field over a frequency range. The RCS of the cavity-backed aperture is calculated using the electric field at different frequencies. Numerical results for a rectangular cavity, a circular cavity, and a material filled cavity are presented over a frequency range. Good agreement between AWE and the exact solution over the frequency range is obtained.
List of Symbols

\( \nabla \) \hspace{1cm} \text{Del operator}

\( \nabla' \) \hspace{1cm} \text{Del operator over the source coordinates}

\( \varepsilon_r \) \hspace{1cm} \text{Dielectric permittivity of the medium in the cavity}

\( \delta_{qo} \) \hspace{1cm} \text{Kronecker delta defined in equation (23)}

\( \mu_o \) \hspace{1cm} \text{Magnetic permeability of free space}

\( \mu_r \) \hspace{1cm} \text{Dielectric permeability of the medium in the cavity}

\( \eta_o \) \hspace{1cm} \text{Intrinsic impedance of free space}

\( \theta_i \) \hspace{1cm} \text{Incident angle in } \theta \text{ direction}

\( \phi_i \) \hspace{1cm} \text{Incident angle in } \phi \text{ direction}

\( \hat{\theta} \) \hspace{1cm} \text{Unit normal along } \theta \text{ direction}

\( \hat{\phi} \) \hspace{1cm} \text{Unit normal along } \phi \text{ direction}

\( \omega \) \hspace{1cm} \text{Angular frequency}

AWE \hspace{1cm} \text{Asymptotic Waveform Evaluation}

\( A^{(q)}(k_o) \) \hspace{1cm} \text{qth derivative of } A(k) \text{ with respect to } k; \frac{d^qA(k)}{dk^q}, \text{evaluated at } k_o

\( b(k) \) \hspace{1cm} \text{Excitation vector}

\( b^{(q)}(k_o) \) \hspace{1cm} \text{qth derivative of } b(k) \text{ with respect to } k; \frac{d^qb(k)}{dk^q}, \text{evaluated at } k_o

\( ds \) \hspace{1cm} \text{Surface integration with respect to observation coordinates}

\( ds' \) \hspace{1cm} \text{Surface integration with respect to source coordinates}

\textbf{E} \hspace{1cm} \text{Electric field}

\( E_{inc} \) \hspace{1cm} \text{Incident electric field}

\( e(k) \) \hspace{1cm} \text{Electric field coefficient vector}

\( \textbf{H}_{inc} \) \hspace{1cm} \text{Incident magnetic field at the surface } S_{inc}
\( \mathbf{H}_{\text{scat}} \)  Scattered magnetic field

\( H_{xi} \)  x-component of the incident magnetic field

\( H_{yi} \)  y-component of the incident magnetic field

\( H_{zi} \)  z-component of the incident magnetic field

\( H_{\theta i} \)  \( \theta \) -component of the incident magnetic field

\( H_{\phi i} \)  \( \phi \) -component of the incident magnetic field

\( H_{\theta s} \)  Scattered magnetic field in \( \theta \) direction

\( H_{\phi s} \)  Scattered magnetic field in \( \phi \) direction

FDTD  Finite Difference Time Domain

FEM  Finite Element Method

\( f \)  Frequency

\( j \)  \( \sqrt{-1} \)

\( k_i \)  As defined in equation (11)

\( k \)  Wavenumber at any frequency \( f \)

\( k_o \)  Wavenumber at frequency \( f_o \)

MoM  Method of Moments

\( M \)  Magnetic current at the surface \( S_{ap} \)

\( m_n \)  \( n^{\text{th}} \) moment of AWE \( (n=0,1,2,3,4 \ldots \ldots) \)

\( \hat{n} \)  Normal unit vector

PEC  Perfect Electric Conductor

\( P_L(\cdot) \)  Polynomial of order \( L \)

\( Q_M(\cdot) \)  Polynomial of order \( M \)

\( q! \)  Factorial of number \( q \)
RCS  Radar Cross Section

$R$  Distance between the source point and the observation point

$T$  Vector testing function

$T_s$  Vector testing function at the surface $S_{ap}$

VLSI  Very Large Scale Integrated (circuits)

$z$  Unit normal along Z-axis
1. Introduction

The electromagnetic characterization of cavity backed apertures is of importance in understanding the scattering properties and in electromagnetic penetration/coupling studies. Recently, there has been a considerable interest in analyzing cavity backed apertures in an infinite ground plane. Various analytical and numerical techniques have been applied for two dimensional cavity backed apertures [1-6]. For three dimensional problems, mode matching has been used for rectangular [7] and spherical [8] cavity backed apertures. A Method of Moments (MoM)/modal [9] approach is used recently to analyze apertures formed by a rectangular cavity recessed in a ground plane. These methods are restricted to cavities with regular shapes, where fields can be written in modal form. In [10], a boundary integral method is used to analyze the scattering from three dimensional cavities via a connection scheme. Though useful for savings in computer memory, this method leads to dense matrices. Also, the accumulation errors due to the connection algorithm are not negligible as the number of subsections increase. In the case of deep cavities, high frequency techniques such as those proposed in [11] and [12] could be effectively implemented. Unfortunately, these techniques are not suitable when the cavity is filled with inhomogeneous materials. In [13], a Finite Difference Time Domain (FDTD) method is applied for large structures. However, the method of FDTD sometimes results in inaccurate results due to differencing, staircasing and dispersion. Jin and Volakis [14] used a finite element-boundary integral formulation which employs the boundary integral equation (or Method of Moments-MoM) to formulate the fields external to the cavity accurately.

In the combined FEM/MoM technique, FEM is used in the cavity volume to compute the electric field, whereas MoM is used to compute the magnetic current at the aperture. For the combined FEM/MoM technique, the cavity is divided into tetrahedral elements and the aperture
is discretized by triangles. Using the Galerkin's technique, simultaneous equations are generated over the subdomains and are added to form a global matrix equation. This results in a partly sparse and partly dense, symmetric complex matrix, which can be solved either by a direct solver or by an iterative solver. The electric field hence obtained is used to compute the RCS of the cavity-backed aperture.

To obtain RCS over a range of frequencies using the combined FEM/MoM technique, one has to repeat the calculations over the frequency range of interest. If the RCS is highly frequency dependent, one needs to do the calculations at the finer increments of frequency to get the accurate representation of the frequency response. This can be computationally intensive and for an electrically large cavity with electrically large aperture, it can be computationally prohibitive despite the increased power of the present generation of computers. To alleviate the above problems, the application of Asymptotic Waveform Evaluation (AWE) has been proposed for the timing analysis of VLSI circuits [15]. The AWE technique is finding increasing interest in electromagnetic analysis of microwave circuits [16-18]. Recently a detailed description of AWE applied to frequency domain electromagnetic analysis is presented in [19]. AWE has been used to predict RCS of PEC bodies over a frequency range [20] and input characteristics of a cavity-backed aperture antenna over a frequency range [21].

In this report, the application of AWE for predicting the RCS over a range of frequencies for a cavity-backed aperture using a combined FEM/MoM technique is described. In the AWE technique, the electric field is expanded in a Taylor series around a frequency. The coefficients of the Taylor series (called 'moments') are evaluated using the frequency derivatives of the combined FEM/MoM equation. These moments are then matched via the Padé approximation to a rational polynomial. Using the rational polynomial, the electric field distribution in the cavity
can be obtained over a frequency range. Using this field distribution, the RCS of the cavity-backed aperture in an infinite ground plane is calculated at any frequency within the frequency range.

The rest of the report is organized as described below. A brief description of hybrid FEM/MoM technique to calculate RCS from a cavity-backed aperture is given in section 2. In section 3, AWE implementation for the combined FEM/MoM technique is described. Numerical results for a rectangular cavity, a circular cavity, and a material filled cavity are presented in section 4. The numerical data are compared with the exact solution (calculated at each frequency using the hybrid FEM/MoM technique) over the frequency range. CPU time and storage requirements for AWE formulation are given for each example and are compared with those required for exact solution at each frequency. Concluding remarks on the AWE technique are presented in section 5.
2. Hybrid FEM/MoM Technique

The geometry of the problem to be analyzed is shown in figure 1. For linear, isotropic, and source free region, the electric field satisfies the vector wave equation:

$$\nabla \times \left( \frac{1}{\mu_r} \nabla \times E \right) - k^2 \varepsilon_r E = 0$$

(1)

where $\mu_r$, $\varepsilon_r$ are the relative permeability and relative permittivity of the medium in the cavity and $k$ is the free space wavenumber. The time variation $\exp(j\omega t)$ is assumed and suppressed throughout this paper. The electric field $E$ is solved via hybrid FEM/MoM technique assuming that cavity-backed aperture is illuminated by a harmonic plane wave, $H_{inc}$. Following the procedure described in [14], equation (1) can be written as

$$\int \int \int_V (\nabla \times T) \cdot \left( \frac{1}{\mu_r} \nabla \times E \right) dv - k^2 \varepsilon_r \int \int \int_V T \cdot E dv - j\omega \mu_o \int \int_S (T \times \hat{n}) \cdot H_{scat} ds$$

$$= 2j\omega \mu_o \int \int_S (T \times \hat{n}) \cdot H_{inc} ds$$

(2)

where $T$ is the vector testing function, $S_{ap}$ is the aperture surface (see figure 1). $H_{scat}$ is the scattered magnetic field and $\hat{n} = \hat{z}$ at $S_{ap}$.

The volume of the cavity is subdivided into small volume tetrahedral elements. The electric field is expressed in terms of the edge vector basis functions [22], which enforce the divergenceless condition of the electric field explicitly. The vector testing function is also expressed in terms of the edge vector basis functions following the Galerkin's method. The discretization of the cavity volume into tetrahedral elements automatically results in discretization of the surface $S_{ap}$ into triangular elements. The volume and surface integrals in equation (2) are carried out over each element to form element matrices, which are assembled to form global matrices. Equation (2) can be written in matrix form as
\[ A(k) e(k) = b(k) \]  \hspace{1cm} (3)

\( A(k) \) is a partly sparse, partly dense complex symmetric matrix, \( b(k) \) is the excitation vector, and \( e(k) \) is the unknown electric field coefficient vector. \( A(k) \) is evaluated as a sum of three matrices.

\[ A(k) = A_1(k) + A_2(k) + A_3(k) \]  \hspace{1cm} (4)

where

\[ A_1(k) = \iiint_T (\nabla \times T) \cdot \left( \frac{1}{\mu_r} \nabla \times E \right) dv - k^2 \varepsilon_r \iiint_T T \cdot E dv \]  \hspace{1cm} (5)

\[ A_2(k) = -\frac{k^2}{2\pi} \iint_{S_{ap}} T_s \cdot \left\{ \iint_{S_{ap}} M \frac{\exp(-jkR)}{R} ds' \right\} ds \]  \hspace{1cm} (6)

\[ A_3(k) = \frac{1}{2\pi} \iint_{S_{ap}} (\nabla \times T_s') \left\{ \iint_{S_{ap}} (\nabla' \times M) \frac{\exp(-jkR)}{R} ds' \right\} ds \]  \hspace{1cm} (7)

\[ b(k) = 2j \omega \mu_0 \iint_{S_{ap}} (T \times \hat{n}) \cdot H_{inc} ds \]  \hspace{1cm} (8)

Equations (6) and (7) are obtained by making use of the equivalence principle and image theory [23] and follow the procedure given in [24]. \( T_s = T \times \hat{n} \) and \( R \) is the distance between source point and the observation point. \( M \) is the equivalent magnetic current over the aperture \( S_{ap} \). \( \nabla' \) indicates del operation over the source coordinates and \( ds' \) indicates the surface integration over the source region. Equation (8) is calculated assuming a harmonic plane wave

\[ H_{inc} = (\hat{\phi} H_{xi} + \hat{\theta} H_{yi} + \hat{\rho} H_{zi}) e^{-jk_i \cdot r} = (\hat{\phi} H_{\theta i} + \hat{\phi} H_{\rho i}) e^{-jk_i \cdot r} \]  \hspace{1cm} (9)

\[ E_{inc} = \eta_0 H_{inc} \times k_i \]  \hspace{1cm} (10)

where
\[ k_i = -k_o \left[ \hat{x}\sin\theta_i\cos\phi_i + \hat{y}\sin\theta_i\sin\phi_i + \hat{z}\cos\theta_i \right] \]  

\[ H_{xi} = \frac{(\sin\alpha\cos\theta_i\cos\phi_i + \cos\alpha\sin\phi_i)}{\eta_o} \]  

\[ H_{yi} = \frac{(\sin\alpha\cos\theta_i\sin\phi_i - \cos\alpha\cos\phi_i)}{\eta_o} \]  

\[ H_{zi} = \frac{(-\sin\alpha\sin\theta_i)}{\eta_o} \]  

\[ H_{\theta i} = |H_{inc}| \sin\alpha \]  

\[ H_{\phi i} = |H_{inc}| \cos\alpha \]  

in which \( \eta_o \) is the free space intrinsic impedance and \( \alpha \) represents the polarization angle of the incident field. When \( \alpha = 0 \), then \( H_{zi} = 0 \) which corresponds to H-polarization and when \( \alpha = \pi/2 \), then \( E_{zi} = 0 \) which corresponds to E-polarization.

The matrix equation (3) is solved at any specific frequency, \( f_o \) (with wavenumber \( k_o \)) either by a direct method or by an iterative method. The solution of the equation (3) gives the unknown electric field coefficients which are used to obtain the electric field distribution. Once the electric field \( E \) is found and hence the magnetic current \( M \) on the aperture, the far zone scattered field can be computed.

\[ \mathbf{H}_{scat}(r)|_{r \to \infty} = -\frac{jk_o}{\eta_o} \frac{e^{-jk_o \sigma}}{2\pi r} \int_{S_a} \left( \hat{\theta} \hat{\phi} + \hat{\phi} \hat{\phi} \right) \cdot \mathbf{M}(x, y) e^{jk_o \sin\theta (x\cos\phi + y\sin\phi)} dxdy \]  

where \( (r, \theta, \phi) \) are the usual spherical coordinates of the observation point. The scattering cross section is then given by

\[ \sigma = \lim_{r \to \infty} \frac{4\pi r^2 |\mathbf{H}_{scat}(r)|^2}{|\mathbf{H}_{inc}(r)|^2} \]
where
\[ |H_{\text{scat}}(\mathbf{r})|^2 = |H_{\theta s}|^2 + |H_{\phi s}|^2 \]  \hspace{1cm} (19)

\[ |H_{\text{inc}}(\mathbf{r})|^2 = |H_{\theta i}|^2 + |H_{\phi i}|^2 \]  \hspace{1cm} (20)

### 3. AWE Implementation

The RCS given in equation (18) is calculated at one frequency. If one needs RCS over a frequency range, this calculation is to be repeated at different frequency values. Instead, AWE can be applied to obtain the frequency response over a frequency range. The general implementation of AWE for any frequency domain technique used for electromagnetic analysis is given in detail in [19]. The solution of equation (3) gives the unknown electric field coefficient vector \( e(k_0) \) at a particular frequency \( f_0 \). Instead \( e(k) \) can be expanded in Taylor series as

\[ e(k) = \sum_{n=0}^{\infty} m_n (k-k_0)^n \]  \hspace{1cm} (21)

with the moments \( m_n \) given by [19]

\[ m_n = A^{-1}(k_0) \left[ \frac{b^{(n)}(k_0)}{n!} - \sum_{q=0}^{n} \frac{(1-\delta_{q0}) A^{(q)}(k_0) m_{n-q}}{q!} \right] \]  \hspace{1cm} (22)

\( A^{(q)}(k_0) \) is the \( q \)th derivative with respect to \( k \) of \( A(k) \) given in equation (4) and evaluated at \( k_0 \). Similarly, \( b^{(q)}(k_0) \) is the \( q \)th derivative with respect to \( k \) of \( b(k) \) given in equation (9) and evaluated at \( k_0 \). The Kronecker delta \( \delta_{q0} \) is defined as

\[ \delta_{q0} = \begin{cases} 1 & q = 0 \\ 0 & q \neq 0 \end{cases} \]  \hspace{1cm} (23)

The \( q \)th derivatives of \( A(k) \) and \( b(k) \) are evaluated and are given in detail in the Appendix.
In many cases, the Taylor series expansion gives fairly good results. However, the accuracy of the Taylor series is limited by the radius of convergence. It will not converge to the right answer beyond the radius of convergence, and it sometimes requires a large number of terms to converge over a frequency range. In such cases, one may want to replace Taylor series expansion with a rational function called Padé approximation \cite{15} to improve the accuracy of the numerical solution.

To obtain Padé approximation, the Taylor series expansion in equation (21) is matched with a rational polynomial \cite{15}

\[
\sum_{n=0}^{\infty} m_n (k - k_o)^n = \frac{P_L (k - k_o)}{Q_M (k - k_o)} \tag{24}
\]

where

\[
P_L (k - k_o) = a_0 + a_1 (k - k_o) + a_2 (k - k_o)^2 + \ldots \ldots + a_L (k - k_o)^L
\]

and

\[
Q_M (k - k_o) = b_0 + b_1 (k - k_o) + b_2 (k - k_o)^2 + \ldots \ldots + b_M (k - k_o)^M
\]

\(b_0\) is set to 1 as the rational function can be divided by an arbitrary constant. Since there are \((L+M+1)\) unknowns, \((L+M)\) moments of the Taylor series should be matched. Equating the coefficients for powers \((k - k_o)^{L+1} \ldots \ldots (k - k_o)^{L+M}\), the coefficients of \(Q_M (k - k_o)\) can be obtained solving the matrix equation

\[
\begin{bmatrix}
    m_{L-M+1} & m_{L-M+2} & \ldots & m_L \\
    m_{L-M+2} & m_{L-M+3} & \ldots & m_{L+1} \\
    \vdots & \vdots & \vdots & \vdots \\
    m_L & m_{L+1} & \ldots & m_{L+M-1}
\end{bmatrix}
\begin{bmatrix}
    b_M \\
    b_{M-1} \\
    \vdots \\
    b_1 
\end{bmatrix}
= \begin{bmatrix}
    m_{L+1} \\
    m_{L+2} \\
    \vdots \\
    m_{L+M}
\end{bmatrix}
\tag{25}
\]
The numerator coefficients can be found by equating the powers \((k - k_o)^0 \ldots \ldots (k - k_o)^L\)

\[
a_o = m_o
\]
\[
a_1 = m_1 + b_1 m_o
\]
\[
a_2 = m_2 + b_1 m_1 + b_2 m_o
\]
\[
a_L = m_L + \sum_{i=1}^{\min(L,M)} b_i m_{L-i}
\]

Once the coefficients of the rational polynomial are obtained, equation (21) can be rewritten as

\[
e(k) = \frac{a_o + a_1 (k - k_o) + a_2 (k - k_o)^2 + \ldots + a_L (k - k_o)^L}{1 + b_1 (k - k_o) + b_2 (k - k_o)^2 + \ldots + b_M (k - k_o)^M}
\]  

(26)

For a given amount of computational effort, one can easily construct a rational approximation which has smaller error than a polynomial approximation. Also for a fixed value of \(L+M\), the error is smallest when \(L=M\) or \(L=M+1\) \([17]\). Using equation (26), the electric field coefficients at frequencies around the expansion frequency are obtained. The electric field hence obtained is used to compute the scattered magnetic field given in equation (17) and finally the backscattering cross section using equation (18).

4. Numerical Results

To validate the analysis presented in the previous sections, a few examples are considered. RCS calculations over a frequency range are done for a rectangular cavity, a circular cavity, and a cavity filled with lossy material. The numerical data obtained using AWE are compared with the results calculated at each frequency using the computer code CBS3DS \([25]\), which implements the combined FEM/MoM technique \([14]\). We will refer to the latter method as “exact solution.”
From section 3, it can be observed that the inverse of matrix $A(k_o)$ is found once and is used repeatedly to find AWE moments. Due to the hybrid FEM/MoM technique, matrix $A(k_o)$ is partly sparse and partly dense. The Complex Vector Sparse Solver (CVSS) [26] is used to LU factor the matrix $A(k_o)$ once and the moments are obtained by backsolving equation (21) with multiple righthand sides. All the computations reported below are done on a SGI-Indigo2 (with 150MHz, IP22 processor) computer.

(a) Square Cavity: A square cavity in an infinite ground plane is considered (fig. 2 with $a=1cm$, $b=1cm$, and $c=2cm$). Backscattering calculations are done with an incident angle $\theta = 0^\circ$ and $\phi = 0^\circ$. The discretization of the square cavity resulted in 3590 total unknowns, and the order of the dense matrix due to MoM is 133. Figure 3a shows the radar cross section over the frequency range 15GHz to 25GHz, calculated using Taylor series for a H-polarized incident wave. The Taylor series moments are calculated at 20GHz. Figure 3b shows the radar cross section over the frequency range 15GHz to 25GHz calculated using Padé approximation. It can be seen from Figure 2b that Taylor series gave good results over the frequency range 18GHz to 22GHz. Beyond this frequency range, there is no improvement in accuracy, even by adding more terms to the Taylor series. However, figure 3b indicates that Padé approximation gave good results over the frequency range 15GHz to 25GHz with $L=5$ and $M=5$, and well behaved convergence is observed with increase in the orders of numerator and denominator of Padé approximation. The timings for the calculations performed using CBS3DS and Padé approximations are given in Table 1. Note that the timings for Taylor series expansion and Padé approximation are the same except for the cost of calculating Padé coefficients from the Taylor
series coefficients. It is observed that the cost of generating moments and the Pade coefficients is very minute compared to the cost of matrix generation and solution.

(b) Circular Cavity: A circular cavity (radius=0.305cm and height=0.3cm) in an infinite ground plane is considered (fig. 4a). The discretization of the circular cavity resulted in 1327 total unknowns, and the order of the dense matrix due to MoM is 132. Backscattering from this cavity is calculated over the frequency range 10GHz to 50GHz with the incident angle $\theta = 0^\circ$ and $\phi = 0^\circ$ and plotted in Figure 4b. The Taylor series moments are calculated at 30GHz. Taylor series expansion is calculated with five moments and the Padé approximation is calculated with $L=3$ and $M=2$. It can be seen that Padé approximation could give accurate results throughout the frequency range, whereas Taylor series gave accurate results only within the frequency range 21GHz to 39GHz. The timings for calculation of backscattering cross section using “exact method” and the Padé approximation are given in Table 1.

(c) Rectangular cavity with lossy material: A rectangular cavity is considered as another example (fig. 2 with $a=1\text{cm}$, $b=0.25\text{cm}$, and $c=0.25\text{cm}$). The cavity is filled with lossy material with dielectric constants $\varepsilon_r = 2.2 - j1.5$ and $\mu_r = 1.8 - j0.1$. The cavity is discretized using tetrahedral elements resulting in 3218 unknowns. The order of the dense matrix due to MoM is 275. The backscatter cross section is calculated over the frequency range 10GHz to 50GHz with the incident angle $\theta = 0^\circ$ and $\phi = 0^\circ$ and plotted in Figure 5a. The incident wave is assumed to be H-polarized. Taylor series expansion is calculated with five moments at 30GHz and accordingly the Padé approximation is calculated with $L=3$ and $M=2$. It can be seen that Padé approximation gave accurate results throughout the frequency range, whereas Taylor series gave accurate results only within the frequency range 22GHz and 38GHz. The backscattering cross
section calculations are also carried out for an E-polarized incident wave with incident angle 
\( \theta = 0^\circ \) and \( \phi = 0^\circ \) and plotted in Figure 5b. Padé approximation is calculated with \( L=5 \) and 
\( M=4 \). Taylor series approximation is calculated with nine moments at 30GHz. It can be seen even for this case that Padé approximation gave accurate results throughout the frequency range 10GHz to 50GHz, whereas Taylor series is accurate only within the frequency range 20GHz to 38GHz. The timings for calculation of backscattering cross section using “exact method” and the Padé approximation are given in Table 1. The discretization for the “exact” calculations using CBS3DS at frequency points beyond 40GHz resulted in 5848 unknowns and order of the dense matrix due to MoM is 421. It can be noted that both Taylor series and Padé approximation are evaluated at 30GHz and hence the dicretization that is used at 30GHz is accurate enough to calculate the hybrid FEM-MoM matrix and the derivative matrices. The results obtained using Padé approximation show a good agreement with the “exact” calculations with denser gridding even beyond 40GHz.

Comment on Storage: In all the above examples, when solving a matrix equation, one needs to store the matrix \( A(k_o) \) for exact solution at each frequency. For \( n^{th} \) order AWE, one needs to store \( n \) number of matrices \( A^{(q)}(k_o) \), \( q=1,2,3,...n \), along with the matrix \( A(k_o) \). For electrically large problems, this could impose a burden on computer resources. This problem can be overcome by storing the derivative matrices, \( A^{(q)}(k_o) \) out-of-core, as the derivative matrices are required only for matrix-vector multiplication.

5. Concluding Remarks

The AWE technique is applied to the hybrid FEM/MoM technique to calculate the radar cross section of a cavity-backed aperture over a frequency range. Examples of a rectangular cavity, a circular cavity, and a material filled cavity are considered to validate the analysis. Both Taylor series approximation and Padé approximation are calculated for all the examples. It can be noted that for the same computational effort, the Padé approximation proved to be superior in terms of wider bandwidth. Timing comparisons are done for calculating radar cross section over a frequency range using AWE and using ‘exact’ calculation at each frequency point. AWE is found to be superior in terms of the CPU time. It may be noted that although calculations are done in frequency increments of 0.1GHz for examples presented in this paper, frequency response at even finer increments can also be calculated at a very nominal cost. This is particularly important when there are sharp nulls present in the frequency response.

Appendix

Derivatives of $A(k)$ and $b(k)$ w.r.t. $k$

The frequency derivatives of $A(k)$ and $b(k)$ are evaluated and are given below. From equation (4):

$$A^{(q)}(k) = \frac{d^q A(k)}{dk^q} = A_1^{(q)}(k) + A_2^{(q)}(k) + A_3^{(q)}(k) + A_4^{(q)}(k) \quad q=0,1,2,3, \ldots \ldots \quad (A.1)$$

From equation (5)

$$A_1^{(0)}(k) = \iiint_V \frac{1}{\mu_r} (\nabla \times T) \cdot (\nabla \times E) \, dv - k^2 \varepsilon_r \iiint_V T \cdot E \, dv \quad (A.2)$$

$$A_1^{(1)}(k) = -2k \varepsilon_r \iiint_V T \cdot E \, dv \quad (A.3)$$

$$A_1^{(2)}(k) = -2 \varepsilon_r \iiint_V T \cdot E \, dv \quad (A.4)$$

$$A_1^{(q)}(k) = 0 \quad q \geq 3 \quad (A.5)$$

From equation (6)

$$A_2^{(0)}(k) = -\frac{k^2}{2\pi} \int_{S_{ap}} \left( \int_{S_{ap}} M \exp\left(-\frac{jkR}{R}\right) ds' \right) ds \quad (A.6)$$

$$A_2^{(1)}(k) = \int_{S_{ap}} \left( \int_{S_{ap}} M \left( \frac{j}{2\pi} \right) \left[ 2k + k^2 (-jR) \right] \exp\left(-\frac{jkR}{R}\right) ds' \right) ds \quad (A.7)$$

$$A_2^{(q)}(k) = \int_{S_{ap}} \left( \int_{S_{ap}} M \left( \frac{j}{2\pi} \right) \left[ \frac{q!}{(q-2)!} (-jR)^{q-3} + 2qk (-jrR)^{q-2} + k^2 (-jrR)^{q-1} \right] \exp\left(-\frac{jkR}{R}\right) ds' \right) ds \quad \text{for } q>1 \quad (A.8)$$
From equation (7)

\[ A_3^{(0)} (k) = \frac{1}{2\pi} \int_{S_{ap}} \left\{ \int_{S_{ap}} (\nabla \cdot T_s) \right\} ds \]

\[ \int_{S_{ap}} \left( \int_{S_{ap}} (\nabla' \cdot M) \frac{\exp (-jkR)}{R} ds \right) ds \]

\[ A_3^{(q)} (k) = \int_{S_{ap}} (\nabla \cdot T_s) \left\{ \int_{S_{ap}} (\nabla' \cdot M) \left( -\frac{j}{2\pi} \right) (-jR)^{q-1} \exp (-jkR) ds \right\} ds \]  

From equation (8)

\[ b^{(0)} (k) = 2j\omega \mu_s \int_{S_{ap}} (T \times \hat{n}) \cdot H_{inc} ds \]  

(A.11)

Noting from equation (9) that

\[ H_{inc} = H_i e^{jk(x_1 + y_1 + z_1)} \]  

where

\[ H_i = \hat{x} H_{x_i} + \hat{y} H_{y_i} + \hat{z} H_{z_i} \]

\[ x_1 = x \sin \theta_i \cos \phi_i \]

\[ y_1 = y \sin \theta_i \sin \phi_i \]

\[ z_1 = z \cos \theta_i \]

and

Equation (A.11) can be rewritten as

\[ b^{(0)} (k) = 2j\kappa \eta_o \int_{S_{ap}} (T \times \hat{n}) \cdot H_i e^{jk(x_1 + y_1 + z_1)} ds \]  

(A.13)
For $q \neq 0$

$$b^{(q)} (k) = \frac{d^q b (k)}{d k^q} = 2q (j)^q \eta_o \int_{S_{ap}} (T \times \hat{n}) \bullet H_i (x_1 + y_1 + z_1) (q-1) e^{jk(x_1+y_1+z_1)} ds$$

$$+ 2k \eta_o (j)^{q+1} \int_{S_{ap}} (T \times \hat{n}) \bullet H_i (x_1 + y_1 + z_1) q e^{jk(x_1+y_1+z_1)} ds \quad \text{(A.14)}$$

**A hybrid Finite Element Method (FEM)/Method of Moments (MoM) technique in conjunction with the Asymptotic Waveform Evaluation (AWE) technique is applied to obtain radar cross section (RCS) of a cavity-backed aperture in an infinite ground plane over a frequency range. The hybrid FEM/MoM technique when applied to the cavity-backed aperture results in an integro-differential equation with electric field as the unknown variable, the electric field obtained from the solution of the integro-differential equation is expanded in Taylor series. The coefficients of the Taylor series are obtained using the frequency derivatives of the integro-differential equation formed by the hybrid FEM/MoM technique. The series is then matched via the Padé approximation to a rational polynomial, which can be used to extrapolate the electric field over a frequency range. The RCS of the cavity-backed aperture is calculated using the electric field at different frequencies. Numerical results for a rectangular cavity, a circular cavity, and a material filled cavity are presented over a frequency range. Good agreement between AWE and the exact solution over the frequency range is obtained.**
