In the microgravity environment of space, the effects of Earth’s gravity are dramatically reduced, allowing scientists to pursue research not possible in ground-based laboratories.
1 Biotechnology
Crystals of recombinant human insulin grown in microgravity are much larger than crystals of the protein grown on Earth. Insulin is a protein that enables our bodies to turn sugar, starches, and other food into energy. Understanding insulin’s molecular structure may lead to better treatments or even a cure for diabetes.

2 Combustion Science
In microgravity, candle flames appear very different than they do on Earth — the reduction in buoyancy-induced convective flows results in a spherical, soot-free, blue flame. In contrast, convective flows created by Earth’s gravity cause a flame to be teardrop-shaped and carry soot to the flame’s tip, turning it yellow.

3 Fluid Physics
In microgravity, when a liquid is heated from the bottom until it reaches its boiling point, bubbles of heated gas stay attached to the container near the source of heat longer and grow larger than they would on Earth, where small bubbles of heated gas form near the bottom of the container and are carried to the top by buoyancy-induced convection.

4 Fundamental Physics
A sample of liquid helium in microgravity experiences a uniform distribution of pressure throughout. However, in Earth’s gravity, the same sample experiences a nonuniform pressure distribution, with the pressure at the bottom of the sample greater than that at the top. Microgravity conditions enable scientists to more effectively probe the underlying physics of the phase change from liquid helium to superfluid helium, which is directly dependent on temperature and pressure. The uniform pressure in the microgravity sample allows the entire sample to undergo the phase change at once.

5 Materials Science
Dendrites are microscopic crystalline structures that form as some molten materials, including metals, solidify. Here, dendrites of pivalic acid form from melted material. Under microgravity conditions, the tip of the dendrite is larger and more blunt, and the sample grows more slowly than the Earth-based sample. While the side branches of the sample grown in microgravity grow only slightly, those in the Earth-based sample experience augmentation as gravity helps transport heat out of the way of the growing branches.
The ongoing challenge faced by NASA’s Microgravity Research Program is to work with the scientific and engineering communities to secure the maximum return from our nation’s investments by (1) assuring that the best possible science emerges from the science community for microgravity investigations; (2) ensuring the maximum scientific return from each investigation in the most timely and cost-effective manner; and (3) enhancing the distribution of experiment data and application of results to maximize their benefits.

NASA Continued to Build a Solid Community of Microgravity Researchers for the Forthcoming International Space Station Era

During fiscal year (FY) 1997, the Microgravity Research Program selected investigations from the 1996 biotechnology, fluid physics, fundamental physics, and materials science NASA Research Announcements (NRAs). The NRA in combustion science will be released in early FY 1998. Principal investigators (PIs) chosen from these NRAs will form the core of the program at the beginning of the International Space Station (ISS) era.

The approximately $105 million research budget supported the work of 329 PIs whose research was published in 576 journal articles and addressed in 647 technical presentations. The release of the National Research Council’s review of microgravity research in support of NASA’s Human Exploration and Development of Space (HEDS) enterprise confirmed that microgravity research has an important role to play in the success of future exploration missions. In preparation for supporting HEDS, the Microgravity Research Division began to focus its research efforts on HEDS goals.

Continuing Strides Were Made in Interagency, International, and Intergovernmental Cooperation

Cooperation with the National Institutes of Health (NIH) continued to address the technical challenges of three-dimensional tissue growth, crystallization of high-quality protein crystals, and early detection of cataracts through the support of multidisciplinary research teams. These teams allow some of the best American scientists and bioengineers to address complex problems and accelerate technology development and transfer. Through NASA-NIH cooperation, NASA has funded 28 research proposals and has also supported NIH-approved researchers to test tissue samples in NASA bioreactors at Johnson Space Center.

Data from microgravity research equipment on the Russian space station, Mir, continue to be analyzed by NASA microgravity scientists and engineers in preparation for operation of the ISS. Planning for ISS facilities continued with respect to the Biotechnology Facility, the Fluids and Combustion Facility, the Low-Temperature Microgravity Physics Facility, and the newly planned Materials Science Research Facility and Microgravity Science Glovebox facility.

Letters of agreement with Japan, Canada, and Germany have improved the research facilities available to U.S. microgravity researchers. Japan’s Large Isothermal Furnace (LIF), Canada’s Microgravity Isolation Mount (MIM), and Germany’s electromagnetic containerless processing facility (TEMPUS) are important resources for investigations in the Microgravity Research Program.

The First Microgravity Science Laboratory Mission and Other Space Shuttle Missions Yielded Significant Results for Microgravity Investigations

The first Microgravity Science Laboratory (MSL–1) mission and its relift (MSL–1R), as well as several Space Transportation System (STS) missions to Mir, yielded a wealth of microgravity data in FY 1997. MSL–1 and MSL–1R included the Middeck Glovebox facility, designed to support experiments that require isolation from the shuttle or space station environment while allowing crewmembers to conduct small-scale investigations and manipulate hardware and materials. Also on the MSL missions, four important pieces of hardware supported biotechnology experiments in protein crystallization and tissue culture: the Protein Crystallization Apparatus for Microgravity, the Single-Locker Thermal Enclosure System, the Second-Generation Vapor Diffusion Apparatus, and Hand-Held Diffusion Test Cells. FY 1997 STS missions carried multiple experiments that were conducted in three internationally developed facilities — LIF, MIM, and TEMPUS — thus broadening the opportunities for international cooperation in space research.

The Microgravity Research Program Expanded Education and Outreach Activities

Microgravity News, which provides quarterly updates on NASA’s Microgravity Research Program, reached increasing numbers of people in the past year. The total distribution of each issue of the newsletter reached over 9,000 for calendar year 1997. Progress continued in FY 1997 on the Microgravity Research Program World Wide Web sites, part of an ongoing effort to integrate numerous microgravity web pages.

Through NASA’s Graduate Student Research Program, seven graduate students received funding to perform ground-based microgravity research in FY 1997, supporting a commitment to encourage the next generation of microgravity researchers. More than 10,000 each of microgravity science educational posters, teacher’s guides, and supplementary curricular materials were distributed at various conferences. Also, over 1,400 teachers requested that they be added to the microgravity education and outreach mailing list. This brought the total number of educators on the mailing list to 3,321 (including 726 kindergarten and elementary, 826 middle school, 1,473 high school, and 296 other educators).

This fiscal year (FY) 1997 annual report describes key elements of the NASA Microgravity Research Program (MRP) as conducted by the Microgravity Research Division (MRD) within NASA’s Office of Life and Microgravity Sciences and Applications. The program’s goals, approach taken to achieve those goals, and available resources are summarized. A “snapshot” of the program’s status at the end of FY 1997 and a review of highlights and progress in ground- and flight-based research are provided. Also described are major space missions that flew during FY 1997, plans for utilization of the research potential of the International Space Station, the Advanced Technology Development (ATD) Program, and various educational/outreach activities. The MRP supports investigators from academia, industry, and government research communities needing a space environment to study phenomena directly or indirectly affected by gravity.

Natural extensions of traditional Earth-based laboratory science, the experiments conducted under the MRP benefit from the stable, long-duration microgravity environment available on orbiting spacecraft. The microgravity environment affords substantially reduced buoyancy forces, hydrostatic pressures, and sedimentation rates, allowing gravity-related phenomena to be isolated and controlled, and permitting measurements to be made with an accuracy that cannot be obtained in ground-based laboratories.

The Microgravity Research Program supports both basic and applied research in five key areas:

- **Biotechnology** — focusing on macromolecular crystal growth as well as the use of the unique space environment to assemble and grow mammalian tissue.
- **Combustion science** — focusing on the processes of ignition, flame propagation, and extinction during combustion of gaseous, liquid, and solid fuels, and on combustion synthesis in a low-gravity environment.
- **Fluid physics** — including aspects of fluid dynamics and transport phenomena affected by the presence of gravity.
- **Fundamental physics** — including the study of critical phenomena; low-temperature, atomic, and gravitational physics; and other areas of fundamental physics where significant advantages exist for studies in a low-gravity environment.
- **Materials science** — including electronic and photonic materials, glasses and ceramics, polymers, and metals and alloys.

Experiments in these areas are typically directed at providing a better understanding of gravity-dependent physical phenomena and exploring phenomena obscured by the effects of gravity. Scientific results are used to challenge or validate contemporary scientific theories, identify and describe new experimental techniques that are unique to the low-gravity environment, and engender the development of new theories explaining unexpected results. These results and the improved understanding accompanying them can lead to improved combustion efficiency and fire safety; reduced combustion-generated pollutants; the development of new technologies in industries as varied as medicine, chemical processing, and materials processing; the development or improvement of pharmaceuticals; and the expansion of fundamental knowledge in a broad range of science disciplines destined to become the foundation for scientific and technological discoveries in the future.

A complementary document to this MRP annual report is the *Microgravity Science and Applications Program Tasks and Bibliography for FY 1997*, NASA Technical Memorandum 206645, February 1998. Detailed information on the research tasks funded by the MRD during FY 1997 is listed in that report, which serves as an excellent reference for supplementary information to this annual report. Also of interest is the *NASA Microgravity Science and Applications Program Strategic Plan*, issued in June 1993, a guide for development and implementation of the MRP plans and activities to the year 2000. The *Marshall Space Flight Center (MSFC) Strategic Implementation Plan*, January 1996, describes MSFC’s Lead Center role for the MRP. Another complementary document is NASA’s *Microgravity Technology Report*, first published in December 1995, summarizing advanced technology development and technology transfer activities through FY 1994. The most recent edition of this report was published in 1998.

Table 1 summarizes information from the *Microgravity Science and Applications Program Tasks and Bibliography for FY 1997* that may be of particular interest to the reader. Data for FY 1993–1996 are shown for comparison with FY 1997 statistics.

Table 2 lists the number of research tasks and types performed at each NASA center for FY 1993–1997.
To use the microgravity environment of space as a tool to advance knowledge; to use space as a laboratory to explore the nature of physical phenomena contributing to progress in science and technology on Earth; and to study the role of gravity in technological processes, building a scientific foundation for understanding the consequences of gravitational environments beyond Earth’s boundaries.

— From the Microgravity Research Program’s Mission Statement

During fiscal year (FY) 1997, the Microgravity Research Program’s lead center for microgravity research was established. The plan to implement the lead center at Marshall Space Flight Center was signed by Arnauld Nicogossian, associate administrator for the Office of Life and Microgravity Sciences and Applications at NASA headquarters (HQ), and by Wilbur Trafton, NASA HQ associate administrator for the Office of Space Flight. The goals listed below were established for the Microgravity Research Program for FY 1997.

### Goal 1
Sustain a leading-edge research program focused in the areas of biotechnology, combustion science, fluid physics, fundamental physics, and materials science that effectively engages the national research community.

### Goal 2
Foster an interdisciplinary community to promote synergy, creativity, and value in carrying out the research program.

### Goal 3
Enable research through the development of an appropriate infrastructure of ground-based facilities, diagnostic capabilities, and flight facilities/opportunities, and promote the use of smaller apparatus.

### Goal 4
Promote the exchange of scientific knowledge and technological advances among academic, governmental, and industrial communities. Disseminate results to the general public and to educational institutions.

### Goal 5
Raise the awareness of the microgravity research community regarding the long-term direction of the Human Exploration and Development of Space enterprise, and discuss with the community the role of microgravity research in support of agency objectives.
Program Overview

The Microgravity Research Program (MRP) enables NASA to meet its mission of advancing and communicating scientific knowledge; using space for human enterprise; and researching, developing, verifying, and transferring advanced space and related technologies by using the low-gravity or “microgravity” environment of space for research. Specifically, the MRP performs the following actions:

- Uses the microgravity environment of space as a tool to advance knowledge.
- Uses space as a laboratory to explore the nature of physical phenomena, contributing to progress in science and technology on Earth.
- Studies the role of gravity in technological processes, building a scientific foundation for understanding the consequences of gravitational environments beyond Earth’s boundaries.

During fiscal year (FY) 1997, the MRP sustained a leading-edge research program, focused on the areas of biotechnology, combustion science, fluid physics, fundamental physics, and materials science, that effectively engaged the national research community. A unique characteristic of the program is the utilization of the NASA Research Announcement (NRA) to solicit research proposals in the five science disciplines listed above. As in previous years, all investigations selected for funding in FY 1997 were reviewed by external peer review panels comprised of leading experts in each of the five fields of study. This use of peer review assures that the research that is proposed and selected is of the highest caliber and merit beneficial to the advancement of the United States. Selections within each of the five science disciplines range from relatively low-resource ground-based research, required to advance analytical and experimental studies requiring a short-duration microgravity environment, to an array of options that range from drop towers and aircraft to space-shuttle-based experiments, which require the relative absence of gravity to observe unique phenomena and behaviors typically masked by the effects of Earth’s gravity.

During FY 1997, NASA continued to work toward the completion of investigations selected for funding in previous years. Additionally, new selections were made in biotechnology, fluid physics, fundamental physics, and materials science. In total, NASA received 657 proposals in response to the NRAs that were released in 1996. Of those proposals, 145 researchers were selected in 1997 to receive grants worth a total of approximately $58 million for conducting ground- and space-based research. The breakdown of recipients by discipline is as follows: biotechnology, 36; fluid physics, 39; fundamental physics, 26; and materials science, 44. Selection of grant recipients in combustion science will take place in FY 1998.

As in the past, the Microgravity Research Program continued to utilize expert advisory groups to guide and validate the value and merit of research conducted in microgravity. The microgravity discipline working groups, which are responsible for maintaining an overview of the efforts in the discipline areas of biotechnology, combustion science, fluid physics, and materials science, continued the process of identifying the most promising areas for scientific investigation and the most advantageous approaches for experimentation, recommending discipline refinements and science priorities and providing an annual program assessment. Of particular note was the charter of a working group for the relatively new field of fundamental physics; the group held its first meeting in FY 1997. Program content, plans, and priorities were reviewed periodically by the Microgravity Research Advisory Subcommittee and the Space Station Utilization Advisory Subcommittee. These subcommittees report to the Life and Microgravity Sciences and Applications Advisory Committee, which reports to the NASA Advisory Council. Additionally, a special committee was convened at the request of NASA to assure that the focus of materials science research aboard the International Space Station (ISS) was of the highest caliber and merit. This group, formed under the auspices of the National Research Council’s Space Studies Board, reviewed and confirmed the nation’s need to advance materials science research.

In FY 1997, the Microgravity Research Program continued to support its research community through ground- and space-qualified apparatus, facilities, and carriers. In support of the relatively large number of analytical and experimental studies requiring a short-duration microgravity environment, ground facilities such as drop tubes and drop towers, and carriers such as parabolic aircraft and suborbital rockets were made available. These facilities and carriers afford from 2.2 seconds to 12 minutes of microgravity, allowing researchers relatively low-cost access to a microgravity environment. To support the space-based investigations, the program selected the most cost-effective option from a broad range of instrumentation, apparatus, and carriers. Primary carriers utilized to advance research requiring a longer-duration microgravity environment included the Space Transportation System (STS) space shuttle missions and the Russian space station, Mir. Additionally, work continued toward the development of facilities to be housed aboard the ISS, which will allow researchers continuous access to a microgravity environment. Launch of ISS component modules is scheduled to begin in 1998.
Space Transportation System Program

FY 1997 saw the flight of five space shuttle missions with significant microgravity experiments aboard: the STS-81 mission in January; the first Microgravity Science Laboratory (MSL–1)/STS-83 in April; the relaunch of MSL (MSL–1R)/STS-94 in July; STS-85 in August; and STS-86 in September. In total, the space shuttle operated for 376 hours in FY 1997, and a number of microgravity investigations took place during its missions. STS-81 supported one materials science investigation. MSL–1 and MSL–1R supported three biotechnology investigations, 4 combustion science investigations, 5 investigations in fluid physics, and 16 materials science investigations. STS-85 supported one investigation each in biotechnology, combustion science, and fundamental physics. The STS-86 mission supported three investigations in biotechnology, one investigation in fluid physics, and one materials science investigation. In late 1997, the fourth United States Microgravity Payload (USMP–4) mission flew in support of a number of microgravity investigations. Details and a summary of experiment results will be available in the FY 1998 annual report.

At the request of the Microgravity Research Program Office, representatives from Marshall Space Flight Center’s Program Development (PD) organization have been investigating alternatives to using the space shuttle for performing research in a low-gravity environment. With this goal in mind, PD is actively pursuing non-shuttle carriers/launch systems such as balloons; sounding rockets; X-34s; and commercially available, expendable launch vehicles for microgravity payload utilization. It is anticipated that the results of this study will provide the necessary information required to begin planning in FY 1999 for potential microgravity research use of these carriers.

Space Station Mir

During FY 1997, the MRP continued to participate in the NASA/Mir Phase 1 program, with the goals of mitigating risk in scientific, technological, logistical, and operational planning for use of the ISS; characterizing the microgravity environment on Mir; and conducting specific U.S. investigations in microgravity research disciplines. The MRP continued to utilize modified space shuttle experiment apparatus, flight samples, science operations, and data analysis/procedures in order to allow U.S. investigators to fully maximize the capabilities of Space Station Mir.

Mir research and support provided early science opportunities during Phase 1 through long-duration science investigations conducted aboard Mir, as well as shorter-duration science investigations on the space shuttle rendezvous missions to Mir. In FY 1997, the MRP significantly increased its participation in scientific experiments conducted on Mir. During this period, three investigative facilities were located on board: the Biotechnology System (BTS), the Microgravity Glovebox (MGBX), and the Microgravity Isolation Mount (MIM). Thirteen long-duration investigations were performed in these facilities. An international cooperative effort was used to transport payloads to these facilities on Mir, using both U.S. STS flights and Russian launch vehicles.

During FY 1997, new technology for protein crystal growth and bioreactors for cell and tissue growth were tested. Samples were exchanged during shuttle flights to Mir. These technologies appear to be promising, based on FY 1997 work. The BTS supported biomedical research during the STS-86 flight of the Biochemistry of Three-Dimensional Tissue Engineering (BIO-3D) experiment. BIO-3D will help scientists design successful tissue culture experiments for the ISS and may also contribute to our fundamental understanding of life systems while in long-term low-gravity conditions.

One of the first pieces of hardware launched to Mir was the MGBX. This facility provides work space, filtration, video recording, lighting, and containment control capabilities to support a large array of on-orbit investigations. During the past year, the MGBX provided investigative resources to support one biotechnology protein crystal growth experiment, one combustion experiment, and three fluid physics experiments. In FY 1997, the MGBX on Mir operated for over 1,000 hours.

To extend the MRP’s international cooperation efforts, the Canadian-sponsored MIM facility was included on Mir. This valuable piece of hardware was launched on an early flight to Mir and has provided acceleration isolation for three experiments: the Canadian Protein Crystallization Experiment, the Queen’s University Experiment in Liquid Diffusion, and the Liquid Metal Diffusion experiment.

The MRP continues to collect data and gain experience in conducting long-duration space flight operations and investigations during Phase 1. The knowledge and techniques refined through various projects will optimize science planning, development of hardware systems and supporting operations, and science return for the ISS. Many lessons have been learned from Phase 1 payload developers and science teams. These lessons are being analyzed in order to improve our future ISS processes and our ability to support a continuous orbiting laboratory.
International Space Station

The development of the ISS is laid out in three phases. Phase 1, which is currently under way, includes up to nine shuttle-Mir docking missions. Phase 2 will begin with the launch of the U.S.-funded/Russian-built and -launched Functional Cargo Block, and will include limited science capabilities. Phase 3 follows and will involve the completion of the pressurized volume space and crew accommodations by integrating the international modules and the U.S. Habitation Module.

During FY 1997, the MRP continued development of its dedicated research facilities for use aboard the ISS. The Biotechnology Facility (BTF), targeted for protein crystallization, tissue culture, and tissue engineering, neared completion of its definition phase. The BTF is scheduled for launch and integration in 2003. The Fluids and Combustion Facility (FCF), designed for a variety of experiments, including investigations in flame spread, turbulent flow, and condensed fuel combustion, completed its requirements definition phase. Launch of the FCF’s components is scheduled to begin in 2001. The test infrastructure for the Low-Temperature Microgravity Physics Facility (LTMPF) was completed in FY 1997. The LTMPF, designed for investigations in fundamental physics, is scheduled to launch in 2004. The Materials Science Research Facility (MSRF), which was designed to expand the range of materials science investigations possible on the ISS, entered its accommodations definition phase. Launch of the MSRF’s components is scheduled to begin in 2001. The Microgravity Science Glovebox (MSG) completed its preliminary design review in April and will begin its critical design review in early FY 1998. The MSG, which was designed to support investigations in all of the microgravity science disciplines, as well as some commercial payloads, is scheduled to launch in 2000.

Exploration

The Microgravity Research Program Office (MRPO) began an effort in late FY 1997 to focus a portion of its research on supporting the development of new technologies required for human exploration of the Moon and Mars. This effort was initiated with a microgravity exploration workshop, which included members of the Mars Exploration Working Group, managed by Johnson Space Center; the Jet Propulsion Laboratory; and members of the NASA academic and industrial microgravity research communities. Areas of potential microgravity research were identified based upon Moon/Mars mission requirements and technology needs. These research areas have been translated into performance goals that will define scientific and resource requirements for implementation in future NRAs. Six grants were awarded for investigations selected from the FY 1996 materials science NRA that will provide data and scientific information to support the Moon/Mars exploration effort. In addition, an experiment designed to characterize dust and soil on Mars during the Mars Surveyor Program 2001 mission has been initiated.

Cooperative Efforts

National Institutes of Health

The FY 1997 NASA appropriations included augmentations for collaborative NASA-National Institutes of Health (NIH) biotechnology programs. In using these funds, NASA emphasized the following areas:

- Continuation of joint NASA-NIH centers to accelerate the transfer of NASA technology and allow its application to biomedical research.
- Development of advanced tissue culturing technology and application of this breakthrough technology to biomedical research and developmental biology.
- Development of advanced protein crystal diagnostic technologies to advance structural biology and drug design to fight a number of diseases.

The NASA-NIH collaboration offers an opportunity to address the technical challenges of three-dimensional tissue growth, crystallization of high-quality protein crystals, and the early detection of cataracts by supporting multidisciplinary research teams. These research teams allow the best American scientists and bioengineers to address these complex problems and accelerate development of the technologies. For acceleration of the pace of technology transfer in the biotechnology areas begun under the NASA-NIH interagency agreement, two multidisciplinary research centers are currently supported: the Massachusetts Institute of Technology in Cambridge, Massachusetts, and the Wistar Institute in Philadelphia, Pennsylvania. Through NASA-NIH cooperation, NASA has funded approximately 28 research proposals and has also supported NIH-approved researchers in testing tissue samples in NASA bioreactors at Johnson Space Center. This has proven to be a very important undertaking in getting researchers to test NASA technology and in gaining acceptance in the larger biomedical community.

During FY 1997, collaborations between NASA and NIH researchers resulted in the first-ever laser light scattering investigation of layers of the eye’s lens. Scientist’s observed that protein cells in the samples varied as a function of the age of the eye, and they were able to look at a precise image of protein cells on each layer of the lens. In September, the Internal Review Board of the NIH’s National Eye Institute approved the protocol for studies of cataracts in human patients using the laser light scattering technique.
The MRP also continued collaborative work with the NIH Laboratory for Structural Biology to develop the next generation of X-ray diagnostic tools for laboratory use. Using new technology, early development has shown this X-ray system to produce a much brighter beam with a significant reduction in power use. This cooperative arrangement will include developing standard manufacturing processes and infusing this new technology into laboratories across the country.

National Institute of Child Health and Human Development

A cooperative effort continued with the National Institute of Child Health and Human Development to transfer NASA’s bioreactor technology for use in AIDS research. Researchers are using cultures of human tonsil, lung, adenoid, and lymph node tissues to assess infectivity of the HIV virus on such tissues.

Juvenile Diabetes Foundation

In FY 1997, NASA entered into a cooperative arrangement with the Juvenile Diabetes Foundation to establish the clinical feasibility of islet cell transplantation, including the ability to grow and preserve pancreatic islet cells and to transplant them with various means of protection, including encapsulation. If successful, restoration of normal blood sugar levels would mark a significant advance in the treatment of diabetes. Even though efficient replacement of insulin would not necessarily “cure” Type 1 diabetes, because the autoimmune process would continue unabated, progress in this area is considered a major step.

International Cooperation

Two furnaces for materials science investigations, the German-designed Electromagnetic Containerless Processing Facility (TEMPUS) and Japan’s Large Isothermal Furnace (LIF), flew aboard MSL–1. TEMPUS allows metals to be cooled to below their freezing points without touching the walls of the containers housing them. The undercooled metals that result from this process exhibit different characteristics than metals allowed to solidify without interference. These differences can include alterations in the strength and brittleness of the material, giving scientists important clues to understanding the link between structure and processing on Earth and in microgravity. TEMPUS supported 10 materials science investigations on MSL–1. The LIF is a vacuum-heating furnace designed to heat large samples uniformly. On MSL–1, five experiments measuring the diffusion coefficients of a variety of materials, including metals, alloys, and semiconductors, and one investigation in liquid phase sintering, were conducted using the LIF. For this mission, the furnace was modified to allow ground control of the heating and cooling processes so that researchers could make real-time changes as their investigations progressed.

Media Outreach

The MRPO stepped up its efforts to communicate the results, benefit, and value of microgravity research in FY 1997. Two World Wide Web pages were enhanced to include more frequent updates on microgravity research. Microgravity programmatic and science highlights are captured respectively on http://microgravity.msfc.nasa.gov/ and http://science.msfc.nasa.gov/. These pages exhibit data of interest to the general public and the education community, as well as the microgravity principal investigator community. An increased emphasis has also been placed on communicating the goals and objectives of the MRP by utilizing NASA media outreach campaigns, which consist of news releases for the print media, live television interviews via the NASA satellite, NASA news videos, and continuing microgravity science briefings on NASA television.
Microgravity Research Conducted in FY 1997

In fiscal year (FY) 1997, researchers in the Microgravity Research Program’s five science disciplines — biotechnology, combustion science, fluid physics, fundamental physics, and materials science — worked to advance human understanding of fundamental physical phenomena and processes through their investigations, which quantify the effects of and overcome the limitations imposed by gravity. Ground-based experiments, coupled with experiments selected for flight definition, comprise a compelling and coherent strategy for understanding and using the microgravity space environment. Highlights of research activity in FY 1997 are presented below.

Biotechnology Overview

Biotechnology is broadly defined as any technology concerned with research on, and manipulation and manufacture of, biological molecules, tissues, and living organisms to produce or obtain products or perform functions. This program uses the microgravity environment to aid in that research. NASA’s microgravity biotechnology program is currently active in two major areas: protein crystal growth and mammalian cell and tissue culture. In the former area, researchers seek to grow protein crystals suitable for structural analysis by X-ray diffraction and to understand how these crystals form. In the second area, investigators study and evaluate the benefit of low gravity for growing cells and tissues. NASA’s Marshall Space Flight Center in Huntsville, Alabama, is the microgravity biotechnology managing center and provides direct support for research in protein crystal growth. NASA’s Johnson Space Center in Houston, Texas, provides support for research in cell and tissue culturing. NASA is also moving ahead with cooperative activities with the National Institutes of Health (NIH) and the Juvenile Diabetes Foundation, as described in the “Program Approach” section of this report.

Funding in biotechnology includes financial support for research centers at the Massachusetts Institute of Technology, Cambridge, Massachusetts; and the Wistar Institute, Philadelphia, Pennsylvania. A cooperative program between NASA and the NIH is continuing for support of research utilizing bioreactor technology. NASA’s Marshall Space Flight Center in Huntsville, Alabama, is also continuing that program with the NIH at the NIH’s Laboratory for Structural Biology. In addition, the NIH is continuing support of research utilizing bioreactors at the Massachusetts Institute of Technology, Cambridge, Massachusetts; and the Wistar Institute, Philadelphia, Pennsylvania.

In the area of protein crystal growth, academic, industrial, and federal government researchers, armed with advanced biotechnology techniques and detailed data on the structure of key molecules, are creating a new generation of drugs. Researchers use data on the structure of proteins to design drugs that will interact with specific proteins and treat specific diseases. This approach promises to produce superior drugs for a wide range of conditions, replacing the trial-and-error approach to drug development that has been the rule for centuries. BioCryst (Alabama), Bristol-Myers Squibb (New Jersey), DuPont Merck (Delaware), Eastman Kodak (New York), Eli Lilly (New Jersey), Schering Plough (New Jersey), Smith Kline Beecham (Pennsylvania), Upjohn (Michigan), and Vertex (Massachusetts) are working with NASA and NASA-funded researchers to produce high-quality protein crystals for new drug development. The first set of such drugs that have resulted from NASA-sponsored research continued to Phase 3 clinical trials — the last set of trials before a new drug can be approved for general use. Although not all drugs successfully complete clinical trials, progression to this stage indicates progress in bringing NASA research results to the general public.

A critical step in drug design is identifying and characterizing the structure of the target molecule. Improving the resolution of protein molecular structures is a difficult process, but it is one that the microgravity environment has been able to advance. This past year has been the best yet in acquiring such critical data. More than 17 of the macromolecules grown in space have revealed information previously unknown regarding their molecular structures. Specific examples of advances in the protein crystal growth area are improved knowledge of the structures of the following proteins:

- **Respiratory Syncytial Virus (RSV)** — an influenza-type virus that produces serious respiratory infections in infants. RSV is responsible for 100,000 to 120,000 hospital admissions per year and approximately 4,000 infant deaths per year in the United States alone.
- **Human Antithrombin III** — a serine protease inhibitor that controls blood coagulation in human plasma. Structural data from the NASA program resulted in the first-ever imaging of the “active loop” of this molecule. These data are crucial to understanding and affecting the function of this molecule.
- **Nucleosome Core Particle and Histone Octamer** — important molecules in fundamental life processes involving the compaction of DNA.
- **Glyceraldehyde-3-Phosphate Dehydrogenase Complex** — a protein used in the development of a drug targeted for treatment of Chagas’ disease.

Growing tissue samples — tissue culturing — is one of the fundamental goals of biomedical research. Scientists can use cancer tumors and other tissues successfully grown outside the
body to test and study treatments, like chemotherapy, without risking harm to patients. Tissues from bioreactors will also offer important medical insights into how tissues grow and develop in the body. Other important cell and tissue models under study include promyelocytic leukemia, human mammary tissue for research on breast cancer, pancreatic islet cells for research on diabetes, liver tissue for research on hepatitis, and human bone marrow.

As a result of a NASA Research Announcement and the associated scientific peer review, 36 new investigations were selected and funded in FY 1997. This brings the total active investigator count in biotechnology to more than 80.

Meetings, Awards, and Publications

The NASA Biotechnology Protein Crystal Growth Conference was held in Montreal, Canada. This meeting addressed fundamental questions in protein crystallization for both flight- and ground-based experiments and provided an international forum for discussion of research and research direction.

The NASA biotechnology cell science investigators working group meeting was held in Houston, Texas, to discuss results from the previous year’s research. Over 100 scientists attended.

Research performed in biotechnology cell science was considered of such importance that the entire May 1997 issue of In Vitro Cellular and Developmental Biology was dedicated to this work. Twelve manuscripts were included in that issue.

Two patents and one licensing agreement were awarded to scientists in the program this year.

Lawrence DeLucas, of the Center for Macromolecular Crystal Growth, received the NASA Public Service Medal for his contributions to NASA and the nation.

Flight Experiments

The NASA/Mir program once again hosted a long-duration biotechnology cell science payload. The Biotechnology Specimen Temperature Controller, a permanent part of the Biotechnology System on the Russian space station, Mir, supported research from three different research teams. Included were studies in neuroendocrine cells by Peter Lelkes, of the University of Wisconsin Medical School; studies on renal tubular cells by Timothy Hammond, of Tulane University; and studies on promyelocytic leukemia cells by Neal Pellis and Thomas Goodwin, of Johnson Space Center. While flights to Mir are primarily designed to develop and validate new technologies in preparation for the International Space Station, scientific studies, such as these, have also been performed during those validations.

Results from these experiments are still pending, as the long-duration increment continues well into 1998.

J. Milburn Jessup, of the University of Pittsburgh Medical Center, was able to fly his investigation of the growth of MIP-101 colon carcinoma cells in order to confirm the previous results. This additional information will enable the publication of his results in a major scientific journal. Growth of such colon cancer cells and tissue allows the formulation of tumor models that are valuable in understanding the dynamic interactions that result in tumor growth and in establishing novel therapeutic strategies.

The protein crystal growth program flew 13 instruments during FY 1997. Those instruments contained more than 3,000 individual samples of a total of 51 different proteins. Evaluation of the results from these flights is in varying stages, depending on the flight date. Structural data returned from these flights will be used to begin or augment the process of drug design. Seventeen improvements in molecular structure were realized in FY 1997.

The FY 1997 biotechnology ground and flight tasks are listed in Table 3. Further details on these tasks may be found in the complementary document Microgravity Science and Applications Program Tasks and Bibliography for FY 1997, NASA Technical Memorandum 206645, February 1998.

Combustion Science Overview

Combustion and the results of combustion processes affect each of us every day. Combustion is responsible for the majority of the world’s electric power production, home heating, and ground and air transportation. Combustion by-products are major contributors to air pollution and global warming. Additionally, unintentional fires claim thousands of lives and cost billions of dollars in property damage. Beneficial control of combustion is impeded by a lack of fundamental understanding of combustion processes. Combustion research is hampered by the effects of gravitational forces more than other areas of science, since combustion intrinsically involves production of high-temperature gases in which low densities trigger buoyant flows. These flows cause the reaction zone to collapse into very thin sheet-like regions that are impenetrable by current or anticipated instrumentation. Conducting experiments in microgravity eliminates buoyancy and expands the reaction zone to the extent that measurements can be made. The resulting data are used to verify combustion theory, validate numerical models, and develop fresh insight into elemental phenomena, all of which can be applied to Earth-based combustion processes.

Specific potential benefits that may ensue, in part, from microgravity combustion research include the following:

- Increased conversion efficiency of chemical energy stored in fuels to useful heat and work in combustion devices, leading to economic savings, reduced dissipation of scarce fuel reserves, and lower greenhouse gas emissions.
- Reduction of combustion-related effluents that pollute the atmosphere.
- Reduction of fire and explosion hazards.
- Improved hazardous waste incineration processes.
- Development of improved materials via combustion synthesis for use in widely diverse applications such as bone replacement, electrical components, and engines.

The microgravity combustion science program, in conjunction with the combustion science discipline working group, has defined the following high priority areas for microgravity research and is supporting research in each area:

Combustion-turbulence interactions: Virtually all practical combustion devices, except gas stoves, involve turbulent flows. Microgravity uniquely limits the range of turbulent length and time scales to those large enough to be tractable experimentally.

Soot processes: Soot is a critical element in many combustion systems, strongly affecting combustor lifetime, efficiency, peak power output, and pollution generation. The lack of buoyancy-induced accelerated flows in a microgravity environment results in longer residence times to investigate primary soot formation, soot clustering, cluster-cluster agglomeration, and oxidation.

Diagnostics: Technological improvements in measurement are a mandate due to historic and valid criticism of the qualitative nature of early microgravity experiments and, more importantly, due to benefits for active control of combustors.

Pressure effects: High pressure and/or supercritical operation of combustors yields improved thermodynamic efficiency at the expense of increased pollutant generation. Conventional diesel engines operate at 50 atmospheres (atm), but most research has been conducted at near ambient conditions (1 atm). The influence of buoyancy increases with pressure.

Benchmark data on laminar flames: Practical devices, although highly turbulent, operate in the “laminar flamelet” regime. As such, improvements in understanding laminar flame structure and associated characteristics have a direct impact on turbulence modeling.

Spray and aerosol cloud combustion: This type of combustion accounts for 25 percent of the world’s energy use yet remains poorly understood from both fundamental and practical perspectives. Microgravity not only offers a quiescent, nonbuoyant environment, it also overcomes the problem of droplet settling in a 1g environment.

Combustion synthesis: Flame-synthesized products include valuable vapors (e.g., acetylene), ultrafine particles (e.g., fullerenes, silicon oxides, titanium oxides), coatings (e.g., diamonds), and monolithic solids (e.g., boron carbide, titanium boride). These materials are rapidly expanding in breadth of use and value, but production remains very much an art, rather than a science. Sedimentation and buoyant plumes lead to short residence times and interfere with investigation into the mechanisms of material production. Current research is geared toward interpreting the differences between normal- and low-gravity processing and improvement of the product.

Surface flame spread: Large-scale fires and fire spread on Earth are complicated by buoyancy-fed turbulent processes and thermal radioactive interactions with surrounding materials, terrain, and building structures. Current models of flame spread generally omit thermal radiation because of the weakness in understanding this transport mechanism. Laboratory-scale experiments in microgravity have begun to elucidate the importance of thermal radiation and indicate that these results might be utilized in modeling large-scale fires.

Transient processes in gaseous flames: Microgravity experimentation can provide insights into flame instabilities, such as ignition, extinction, and imposed perturbations that are often masked by buoyancy in normal gravity.

Spacecraft fire safety: Models used to study spacecraft fire safety are still considered “primitive.” Further research is required in the areas of microgravity flammability, fire spread, fire and smoke detection, fire suppression, and postfire cleanup.

Partial-gravity combustion: Combustion issues on the surfaces of the Moon and Mars will include habitat fire safety, waste incineration, roving vehicle power, and propellant storage safety.
Meetings, Awards, and Publications

The fourth International Microgravity Combustion Workshop was held in Cleveland, Ohio, May 19–21, 1997. Attendance at the workshop reached a new record of 264 registrants. There were 89 technical presentations and 3 plenary/programmatic presentations; proceedings were distributed at the conference.

Chung Law, of Princeton University, was selected to receive the prestigious American Society of Mechanical Engineers Heat Transfer Memorial Award in Science. The award read, in part, “for outstanding contributions to heat and mass transfer in chemically reacting systems, especially on droplet and spray combustion, flame structure and dynamics, and boundary-layer combustion.” Law, principal investigator (PI) for the Studies of Flame Structure in Microgravity investigation, gave special thanks to the microgravity combustion science program for its support of the work leading to this award.

A paper titled “Quantitative Rainbow Schlieren Deflectometry” by Paul Greenberg, Robert Klimek, and Donald R. Buchele was selected as the NASA Lewis Distinguished Scientific Publication of the Year. The paper was published in Applied Optics.

Flight Experiments

Fiscal year (FY) 1997 was a banner year for microgravity combustion science flight experiments. For the second consecutive year, successful flight investigations were conducted in half the research topic areas and on all available carriers. Additionally, the first multiuser combustion facility, Combustion Module-1 (CM-1), demonstrated design concepts and operation techniques that are essential to conducting operations on the International Space Station (ISS).

The first Microgravity Science Laboratory (MSL–1) mission flew twice in 1997. Although the first flight in April was cut short due to an orbiter fuel cell problem, three of the four combustion investigations were operated and all produced publishable data. After an unprecedented turnaround, the mission relit in July as MSL–1R; over 100 fires were set and studied during the relight.

The Laminar Soot Processes (LSP) and the Structure of Flame Balls at Low Lewis Number (SOFBALL) investigations were conducted in the CM-1, CM-1, which is described in more detail in the “Hardware” section of this report, provided common laboratory services, such as data processing/storage, command/communications, containment, and gas management/cleanup to both investigations. The specific apparatus for each investigation was easily integrated with CM-1 as an on-orbit procedure. This type of operation is prototypical of the way combustion science will be conducted in the Fluids and Combustion Facility on the ISS.

The LSP experiment provided observations of soot processes within nonbuoyant, nonpremixed flames that are relevant to practical combustion in aircraft propulsion systems, diesel engines, and furnaces, but with the flames slowed and spread out to allow measurements that are not tractable within the practical flames. Initial analysis of the new measurements suggest the existence of universal relationships between soot processes and the degree of mixing within nonbuoyant flames. These relationships are known as the soot paradigm, a controversial hypothesis based upon indirect observations of practical nonbuoyant flames. If the paradigm proves to be true, it offers simplified ways to control and model soot processes in practical flames. The new measurements yielded the first-ever observations of steady, soot-containing, nonbuoyant flames both with and without soot emissions. These flames provided textbook examples of soot formation processes in practical flames that are invaluable for developing methods for controlling the emissions of pollutant soot.

SOFBALL explores the behavior of newly discovered flame phenomena called “flame balls.” These spherical, stable, stationary flame structures, observed only in microgravity, provide a unique opportunity to study the interactions of the two most important processes necessary for combustion (chemical reaction, and heat and mass transport) in the simplest possible configuration. The preliminary data obtained during the test runs result in the following conclusions:

- Steady, nearly stationary flame balls exist in an extended-duration microgravity environment.
- The extended length of the burns verifies the theoretical predictions that these flames evolve on a very slow time scale, on the order of hundreds of seconds.
- The flame balls are sensitive to orbiter thruster firings above 50 micro-g seconds. During free drift periods, the flame balls were nearly motionless for many minutes, while the flame balls moved slightly after vernier thruster firings or water dumps.
- All the flame balls, regardless of the inert component, number of flame balls, or pressure, produced 1 to 1.8 watts of radiant power, in disagreement with premission predictions.

The Droplet Combustion Experiment (DCE) is designed to investigate the combustion aspects of single, isolated droplets under different pressures and ambient oxygen concentrations for a range of droplet sizes varying between 2 and 5 mm. The DCE runs during the MSL–1 mission identified three regimes of droplet combustion. In addition to the well-known quasisteady regime, in which the squares of both droplet and flame diameters decrease linearly with time and diffusive extinction of the flames occurs when the droplet becomes sufficiently small, two previously undocumented regimes were discovered. For sufficiently large droplets, there is a regime of radiative extinction in which energy loss by emission of infrared radiation causes flame extinction during the initial stage of flame expansion, leaving a large fuel droplet that slowly vaporizes in the hot gases left behind after combustion has ceased. At sufficiently high oxygen content, there is a regime of droplet disappearance in which the flame persists in an outer transient region after the droplet has vaporized completely. This flame rapidly contracts at the end of the burn, extinguishing diffusively at a nonzero flame radius.
The Fiber-Supported Droplet Combustion (FSDC-2) experiment studied fundamental phenomena related to liquid fuel droplet combustion in air. Pure fuels and mixtures of fuels were burned as isolated single and duo droplets with and without forced air convection. The FSDC-2 investigation was conducted in the Microgravity Glovebox facility of the shuttle’s Spacelab during MSL–1R.

Four sounding rocket flights were conducted in FY 1997. The Diffusive and Radiative Transport in Fires (DARTFire) experiment completed its final three flights to investigate flame initiation, fire spread, and postspread steady-state combustion of a thick solid-fuel sample under various low-speed oxidizer flows. Small amounts of radiant heating were imposed on the fuel samples to determine the effects of this kind of assisted heating of the fuel sample on flame survivability and spread. DARTFire marks the first experimental control and measurement of radiative heating in a microgravity combustion experiment. The imposed radiative heating is realistic in the sense that nearby burning material provides radiant heating in both practical and accidental fires.

The fourth sounding rocket flight for the Spread Across Liquids (SAL) investigation occurred on September 10, within 30 minutes of the final DARTFire launch. This dual launch saved range costs. SAL-4 continued the investigation of flame spread over a long, deep pool of liquid fuel in an extended-duration, low-gravity environment. In SAL-4, gas-phase flow visualization was attempted for the first time, and the smoke tracing systems performed perfectly. The gas-phase recirculation cell ahead of the spreading flame could be observed throughout the full fields of view of every planned camera view, as well as the schlieren view. Visualization of the vortex by the smoke tracer was sufficiently high in resolution that rotation rates of the vortex in the cell can be calculated.

The Solid Surface Combustion Experiment flew for the ninth time on the 85th Space Transportation System (STS-85) mission. This flight investigated the behavior of a long, flat polymethyl methacrylate (PMMA) sample ignited in the “near extinction” atmosphere of 50 percent oxygen and 50 percent nitrogen at 1 atm of pressure. The objective of this experiment was to test the theory that flame spread over thick fuel samples is inherently unsteady in quiescent environments. In flight, the PMMA sample ignited normally with a flame that spread at a gradually slower rate. The flame eventually stopped spreading, receded, then quenched. This behavior, never before observed experimentally, was predicted by the PI’s model.

The FY 1997 ground and flight tasks for combustion science are listed in Table 4. Further details on these tasks may be found in the complementary document Microgravity Science and Applications Program Tasks and Bibliography for FY 1997, NASA Technical Memorandum 206645, February 1998.

Fluid Physics Overview

Fluid physics is the study of the motion of fluids and the effects of such motion. Since three of the four states of matter (gas, liquid, and plasma) are fluid, and even the fourth (solid) behaves like a fluid under many conditions, fluid physics encompasses a wide spectrum of industrial, as well as natural, processes and phenomena. Fluid motions are responsible for most transport and mixing that take place in the environment, in industrial processes, in vehicles, and in living organisms. The ultimate goal of research in fluid physics is to improve our ability to predict and control the behavior of fluids in all of the above instances, so as to improve our ability to design devices and operate them. Fluid motion in most situations is strongly influenced by gravity. The low-gravity environment of space offers a powerful research tool for the study of fluid physics, enabling the observation and control of fluid phenomena in ways not possible on Earth. Experiments conducted in this environment have clearly demonstrated the value of microgravity by revealing results that are either completely unexpected or unobservable in Earth’s gravitational field. These results are providing new insight into the behavior of fluids in terrestrial environments.

The microgravity fluid physics program currently has four major research areas: complex fluids, interfacial phenomena, dynamics and instabilities, and multiphase flows and phase change. There are 71 ground-based and 20 flight/flight definition principal investigators (PIs) conducting experimental research as well as developing the theoretical framework for understanding the effects of gravity on processes involving fluids. Work in complex fluids covers colloids, foams, granular media, rheology of non-Newtonian fluids, and emulsions and suspensions. Interfacial phenomena include liquid-vapor interface configurations, contact line dynamics, capillary-driven flows, and the shape stability and breakup of liquid bridges and drops. Dynamics and instabilities include thermocapillary and thermosolutal flows, biofluid mechanics, geological fluid flows, pattern formation, and electrokinetics and electrochemistry. Multiphase flows and phase change include flow patterns in liquid-vapor/gas flows in microgravity, nucleate boiling and its control using acoustic and electric fields in microgravity, and flows of gas-solid and liquid-solid mixtures in microgravity.

The NASA Research Announcement for microgravity fluid physics was released in December 1996. A total of 228 proposals were received in response, showing vigorous interest in microgravity fluid physics in the research community.

Some of the highlights of microgravity fluid physics research conducted in space as well as on Earth are included below.

- Startling and completely unexpected observations were made in the physics of colloids when Paul Chaikin and William Russell, of Princeton University, discovered that colloidal crystals nucleate and grow faster in microgravity than in 1 g. Indications of a possible cause come from a comparison of flight and ground dynamic data. These data suggest that the characteristic time scales for particle motion and rearrangement may be longer in gravity than in microgravity. This is completely unexpected, and as such, it deserves further investigation. These observations resulted from the Physics of Hard Spheres Experiment conducted on the first Microgravity Science Laboratory (MSL–1) mission on the 83rd Space Transportation System flight (STS-83) and its subsequent relight on STS-94. Precise light scattering measurements confirmed what was observed in a prior space experiment, Colloidal Disorder-Order Transition: that colloidal crystals in microgravity have a random, hexagonal, close-packed structure rather than the face-centered cubic structure predicted by theory (Zhu, et al., Nature 387 [26 June 1997]). The understanding of phase transitions is one of the most important problems in the field of condensed matter physics today. For this reason, physicists have long studied suspensions of simple hard spheres as models of phase transformations. These experiments on colloidal suspensions conducted in space have provided definitive conclusions that microgravity provides scientists with a unique tool to probe the secrets of nature hitherto concealed behind the veil of gravity.

- David Weitz, of the University of Pennsylvania, reported unexpected findings from his glovebox investigation, Binary Colloid Alloy Test, which was completed on the Russian space station, Mir, in January 1997. Photographic data were collected on 10 slowly growing samples of the binary colloidal alloys over a period of 90 days, along with rapid growth data on 5 samples of colloidal gels formed from the mixtures of colloidal particles and polymers. On Earth, these mixtures (colloid/polymers) form structures that collapse, presumably due to gravitational forces, after some latency time, which varies from 20 minutes to an hour. In the low-gravity environment of space on Mir, these structures were observed for several hours without collapse, indicating that the collapse observed on Earth is due to gravitational forces. Weitz considers this a very important finding and believes that the microgravity environment of space will allow him to study the equilibrium structures previously unachievable on Earth. Long-term growth of binary colloidal crystal alloys also showed surprising results. The sample with a volume fraction of 0.54, which did not crystallize on Earth, showed large crystals in space. This again indicates the influence of gravity on these processes and a clear benefit of conducting the experiment in space.

- The first-ever observation of a metastable liquid-vapor interface configuration was made in the Interface Configuration Experiment, a glovebox investigation conducted on Mir by astronaut Shannon Lucid. This experiment was devised to investigate the equilibrium behavior of liquid-vapor interfaces in microgravity and to verify results of mathematical models that are nearly impossible to realize in 1 g. Experiments...
verified predictions of the mathematical model developed by Paul Concus, of the University of California, Berkeley, and Robert Finn, of Stanford University, in that in a symmetrical vessel, a nonsymmetric spoon-shaped interface was most stable, a saddle-shaped interface was less stable, and a symmetric concave shape was least stable. The results, which cannot be obtained on Earth, will be used to guide the use of mathematical and numerical techniques in predicting the configuration and stability of a broader range of fluid interfaces in low-gravity environments.

- In ground-based research, Harry Swinney, of the University of Texas, reported the first-ever experimental observation of long-wavelength instability in his experiments using very thin liquid layers, where the effect of gravity is negligible. A short-wavelength instability results in the formation of well-known hexagonal cells. Although this long-wavelength instability was predicted 35 years ago, it had not been observed previously. Swinney has also developed a numerical simulation that provides results which are in qualitative agreement with his experimental observations. This instability could become the primary instability in a microgravity environment.

- Jungho Kim, of the University of Denver, has developed an array of 96 micro heaters (0.25 mm x 0.25 mm) with the capability of running each heater in a constant temperature or constant heat flux mode through software control. This technique has the potential to answer many important questions involving boiling phenomena. For example, one relatively new hypothesis regarding critical heat flux involves looking at the surface temperatures during the boiling process. If the surface temperature is not lowered to below the Leidenfrost temperature (the temperature where a stable vapor film is formed on the surface) during the bubble departure cycle, then colder fluid from the bulk is not able to rewet the surface, and critical heat flux occurs. This can easily be tested by operating the heaters in the array in a constant power mode and using the individual heaters to map out the temperature variations on the surface during boiling.

Meetings, Awards, and Publications

Microgravity fluid physics PI Eric Kaler, of the University of Delaware Division of Colloid and Surface Chemistry, won the 1998 American Chemical Society Award in Colloid or Surface Chemistry, sponsored by Procter & Gamble. The purpose of this award is to recognize and encourage outstanding scientific contributions to colloid or surface chemistry in the United States or Canada.

Two microgravity fluid physics PIs, James Jenkins, of Cornell University, and Robert Behringer, of Duke University, organized an international conference titled “Powders and Grains 97” at Duke University in May 1997. Nobel Laureate P. G. de Gennes, of the Collège de France, was the conference’s keynote speaker. He gave a talk titled “Avalanche of Granular Materials.” Several microgravity fluid physics PIs also presented papers at the conference.

Many of the fluid physics PIs served on expert panels or chaired sessions at a workshop called “Research for Space Exploration: Physical Sciences and Processes Technology,” which was held August 5–7, 1997, in Cleveland, Ohio, and was organized by Brad Carpenter and Alexander Pline, both of NASA headquarters. The purpose of the workshop was to facilitate communication between the research community, mission planners, and industry technical experts, with a goal of defining enabling research for the NASA Human Exploration and Development of Space enterprise.

The following meetings and conferences of note also took place during FY 1997:

Flight Experiments

Data from the Surface Tension-Driven Convection Experiment (STDCE-2), conducted on the second United States Microgravity Laboratory (USML–2) mission, are still being analyzed. The STDCE-2 data, together with the ground-based data, show that the Marangoni number at the onset of oscillations varies with the container size, which means that the Marangoni number cannot describe the onset. Simon Ostrach and Yasuhiro Kamotani, both of Case Western Reserve University, have derived surface deformation parameters for constant temperature and constant flux configurations based on the physical model of oscillations. The model assumes that the deformability of free surface plays an important role in the oscillation mechanism. The surface deformation parameters are found to correlate with the STDCE-2 data and the ground-based data with smaller containers very well. Another important objective is to determine the velocity and temperature fields and the free surface motion during oscillations. Those quantities must have certain phase relations, according to the model of oscillations. At present, the Ronchi data are still being analyzed to determine the free surface motion. The imager data for the free surface temperature distribution have been analyzed.

Data analysis has been completed for the Pool Boiling Experiment, which successfully finished its last two relights. The primary objective of the last two relights, on STS-72 (January 1996) and STS-77 (May 1996), was to determine the factors governing the onset of dryout and/or rewetting on a flat heater surface. On the STS-72 mission, the subcooling levels were increased, while on the STS-77 mission, the heat flux levels were reduced. Subcooling was observed for all but the very highest heat flux levels. For lower levels of heat flux where dryout did not take place, it appeared that the excess surface energy associated with the coalescence of bubbles was sufficient to impel the resulting combined bubble away from the vicinity of the heater surface. This was sufficient to stir the liquid so as to bring the subcooled liquid to the heater surface.

Data analysis has nearly been completed for the relight of the Thermocapillary Migration of Bubbles and Drops in Microgravity experiment, which was successfully completed on the Life and Microgravity Spacelab (LMS) mission, STS-78, utilizing the European Space Agency (ESA) facility known as the Bubble, Drop, and Particle Unit (BDPU). R. Shankar Subramanian, of Clarkson University, and Ramaswamy Balasubramaniam, of Lewis Research Center, report that in the case of isolated drops and bubbles, the LMS data appear consistent in overall trend with data from the second International Microgravity Laboratory (IML–2) while extending the range of values of the Marangoni and Reynolds numbers. Also, in axisymmetric runs in the LMS experiments, they observed, as in the case of the IML–2 experiments, that a small leading drop substantially lowered the migration speed of a larger trailing drop. However, some additional phenomena have been observed in the LMS runs that were unanticipated and interesting. In some experiments involving pairs of drops, a small leading drop moved virtually along the axis of the cell, while a larger trailing drop moved off the axis. They also found a couple of cases of pairs of air bubbles that displayed the same asymmetric behavior in the LMS runs. Another even more interesting observation is that liquid drops in some instances moved in three-dimensional paths that were complex but appeared to be approximately helical.

Dudley Saville, of Princeton University, obtained completely unexpected results in his electrohydrodynamics experiments on the stability of liquid bridges. These experiments were also carried out on the LMS mission utilizing the BDPU. A high-voltage power supply provided voltages up to 20 kV in either AC or DC modes. Frequencies up to 500 Hz were employed. It was found that the DC field strengths required to stabilize liquid bridges in the gas were much higher than were predicted from simple scaling arguments based on the earlier ground-based two-liquid experiments and the pinned-cylinder theories developed so far. Also, the fluid bridges could not be stabilized using the AC field at strengths well over the theoretical predictions. Some new observations were a hysteresis in the field strength versus liquid bridge shapes and large, sustained oscillations under certain conditions with DC fields. Parenthetically, this experiment was a successful demonstration that one can design, fabricate, and carry out a first-class experiment in a relatively short time span. The total elapsed time from the science concept review to the flight was only a little over 18 months.

The Angular Liquid Bridge investigation, designed by Paul Concuc, of the University of California, Berkeley, was conducted by astronaut Jerry Linenger in late February 1997 in the Mir glovebox on the Mir–23/NASA–4 mission. The experiment was designed to explore the striking behavior of liquid–vapor interfaces in a low-gravity environment under which major shifts of liquid can arise from small changes in container configuration or contact angle. The major portion of the experiment examines configurations that liquid drops may assume between planar surfaces that may be tilted with respect to each other. Impetus for this investigation arises mainly from contrasting results obtained using classical theory. The insight gained by such work is basic for the design and analysis of fluid systems in space, such as those used for management of liquid fuel and oxygen, for thermal systems (capillary-pumped loops, heat pipes), and for biological processes (wastes and waste recycling).

The Capillary Heat Transfer investigation, designed by Kevin Hallinan, of the University of Dayton, was conducted on MSL–1 in July 1997 to investigate instabilities and failures in capillary-pumped loops (CPLs) in microgravity. CPLs require no power and can be used in satellites to transfer heat with high efficiency from electrical components to space radiators. CPLs have proven to be unreliable in space operations, and the explanation has been elusive. This experiment answered many of those questions. The glovebox investigator did observe the instabilities in the evaporator meniscus, as expected, for a capillary heat transfer device in microgravity. For heat input from the vapor side of the meniscus, the instabilities, though present, had little impact on the operation of the device. For heat input on the liquid side of the meniscus, the
NASA has selected this experiment for flight on a sounding rocket. The experiment's scientific merit as well as the engineering feasibility. As a result, engineering panels reviewed and approved the experiment's investigation was held in July 1996. Nonadvocate science and scheduled for the March 1999 time frame. The RDR for this experiment is to complete the 10-test matrix (two tests/flight). The first flight is planned to use a Terrier Black-Brant 10.0, and two Newtonian tests using the oligomeric polystyrene Boger fluid covering the Deborah number range of 0.10 to 0.025 wt% of high molecular weight (MW) monodisperse polystyrene. The test fluid selected for this investigation is Boger fluid composed of 0.025 wt% of high molecular weight (MW) monodisperse polystyrene. The complete test matrix involves eight non-Newtonian tests on the Boger fluid covering the Deborah number range of 0.10 to 10.0, and two Newtonian tests using the oligomeric polystyrene only. The experiments will be conducted on a Terrier Black-Brant sounding rocket with an MK70 booster that provides a microgravity environment. Rotation control of a drop in microgravity was investigated. The ultimate capability of the single-axis levitator will be determined from the acquired information. Preliminary observations indicate a residual steady rotation of about 0.1 revolution per second with the acoustic power required to counteract the shuttle attitude control firings. High rotation rates necessary for drop bifurcation and fission have also been measured. Tracer particles within the deployed drops have allowed the measurement of the rotation rate, and they will yield quantitative information on the dependence of acoustic torque on pressure, as well as the assessment of the internal flow within a quasi-isothermal drop in the Spacelab environment.

The Bubble and Drop Nonlinear Dynamics glovebox investigation, by L. Gary Leal, of the University of California, Santa Barbara, and Trinh, was also conducted on MSL–1. They obtained new data not collectable in 1 g on bubble nonlinear dynamics. An effective method for bubble positioning and manipulation has been discovered, and an ultrasonic method for bubble removal has been demonstrated. The first data for nonlinear shape oscillation, free-decay frequency information for a totally free drop (no positioning force field present), were obtained, and the technique for acquiring such information was validated. Nonlinear bubble response to modulation of a combination of fundamental and harmonic ultrasonic fields has been recorded, and new behavior not previously observed has also been recorded. Large-amplitude bubble shape oscillations were excited for the first time in low gravity. The required ultrasonic field configuration for controlled bubble positioning in microgravity has been empirically determined. The first data for nonlinear shape oscillation, free-decay frequency information for a totally free drop (no positioning force field present), were obtained, and the technique for acquiring such information was validated. Nonlinear bubble response to modulation of a combination of fundamental and harmonic ultrasonic fields has been recorded, and new behavior not previously observed has also been recorded. Large-amplitude bubble shape oscillations were excited for the first time in low gravity. The required ultrasonic field configuration for controlled bubble positioning in microgravity has been empirically determined on orbit. The method used in 1 g has been shown to fail in low gravity. Verification of the capability of an ultrasonic method for bubble removal from the liquid bulk within a closed vessel has been successfully demonstrated.

Stein Sture, of the University of Colorado, is preparing to fly the Mechanics of Granular Materials experiment on Space Shuttle Discovery’s STS-89 mission, scheduled for January 15, 1998. The experiment was previously flown on Atlantis in September 1996. The Marshall Space Flight Center-sponsored experiment will test six soil specimens. Three will be subjected to the same controlled-displacement monotonic loading and unloading cycles used in the first flight; the other three will be subjected to cyclic loading. Results from the experiment’s first flight showed that at low confining pressure, the soil is much stronger and stiffer than expected based on experience with similar materials on Earth. The soil specimens
will be studied using various soil mechanics measurements and video imaging while in space. After the experiment, the specimens will be impregnated with an epoxy to stabilize the sample for postmission cross-cut sectioning and various internal imaging techniques. Specimens from the previous mission were studied using X-ray computer tomography scans performed at the Los Alamos National Labs in New Mexico. This was the first time the nondestructive imaging technique was successfully used on a soil particle experiment. Data about the soil deformation were also obtained from video images taken on orbit and from laser profilometer testing, which was used to ascertain precisely how the surface of each specimen was deformed during the experiment.

The fiscal year (FY) 1997 ground and flight tasks for fluid physics are listed in Table 5. Further details on these tasks may be found in the complementary document Microgravity Science and Applications Program Tasks and Bibliography for FY 1997, NASA Technical Memorandum 206645, February 1998.

### Table 5  Fluid physics tasks funded by the Microgravity Research Division in FY 1997

The goal of the fundamental physics program is to use the microgravity environment of space to shed light on the most fundamental physical laws that govern the behavior of matter. An understanding of these laws, and the advanced technology developed in order to study them with unprecedented precision, are useful in applications that support and enhance human presence in space, improve the quality of life on Earth, and contribute to the competitiveness of American industry. The microgravity fundamental physics research program currently includes research in the areas of low-temperature and condensed matter physics (LTCMP), laser cooling and atomic physics (LCAP), and gravitational and relativistic physics (GRP). One of the strengths of the fundamental physics discipline is the significant synergy that exists across the three subdisciplines in terms of both scientific convergence and overlap in experimental techniques. Both experimental and theoretical research is being funded.

In fiscal year (FY) 1997, the focus in the LTCMP area was on high-resolution tests of the renormalization group (RG) theory, studies of finite size effects in matter, studies of quantum solidification, and studies of levitated helium drops. The RG theory constitutes one of the greatest achievements of theoretical physics in the past 30 years. The increased understanding of the validity of use of the RG theory in such disciplines as percolation, pattern formation, and evolution of turbulence will help scientists develop better models for how water seeps through soil, how frost heaving occurs in arctic climates, and how turbulent weather systems evolve, among other things.

In the LCAP area, the research focus over the last year has been on development of advanced clocks; studies of fundamental forces and symmetries of nature, such as measurements of the electric dipole moment of the electron; and studies of Bose-Einstein condensation (BEC). An advanced technology development proposal to develop the core flight technology required for LCAP investigators currently in the program was successfully defended. The development of this technology will serve as the first step in providing LCAP investigators access to space.

In the GRP area, the research focus in the last year has been on development of advanced hardware to perform high-resolution tests of Einstein’s equivalence principle. The Satellite Test of the Equivalence Principle (STEP) experiment has the objective of testing an underlying postulate of the theory of general relativity — the principle of the equivalence of inertial mass and gravitational mass — to a precision of about one part in 10^9. Efforts last year focused on developing and demonstrating several critical technologies required for the STEP instrument, particularly in regard to superconducting accelerometers. Agreements for cooperation are being negotiated with representatives of the European Space Agency (ESA) and with national space agencies in Europe. To firmly validate the scientific importance of STEP, it was reproposed as part of the 1996 Fundamental Physics NASA Research Announcement (NRA). The results of the evaluation are expected to become available early next year.

The requirements definition review (RDR) for Critical Dynamics in Microgravity (DYNAMX) was conducted in February 1997. The science and programmatic/engineering review panels recommended additional work be completed prior to proceeding to flight. Both panels recommended a delta RDR in about a year. NASA headquarters and the Microgravity Research Program Office at Marshall Space Flight Center endorsed this recommendation. The DYNAMX project team reacted to the RDR recommendations by reorganizing activities under direct science leadership strengthened by the addition of John Lipa, of Stanford University, as a technical consultant and David Goodstein, of the California Institute of Technology, as an overall science consultant. Sensors have been redesigned and refabricated, and the process of incorporating this new hardware into the ground test facility in order to conduct the final testing required to demonstrate experiment feasibility is under way. In August, the project was directed to replan for flight on the International Space Station (ISS) Low-Temperature Microgravity Physics Facility (LTMPF) in 2003. Specific scientific accomplishments by DYNAMX reported in the open literature include the first experimental observation of self-organized criticality in 4He and preliminary results indicating the existence of nonlinear thermal transport previously predicted by theory. Robert Duncan, of the University of New Mexico, is the principal investigator (PI) for DYNAMX.

The Microgravity Scaling Theory Experiment (MISTE) is a flight definition experiment planned for operation on the ISS. Martin Barmatz, of the Jet Propulsion Laboratory (JPL), is the PI for this experiment. MISTE will measure three critical exponents near the gas-liquid critical point in 3He in the same apparatus, thus allowing rigorous tests of theories for the scaling and hyper-scaling relationships between these exponents. Performing the measurements in microgravity will permit these critical parameters to be measured very close to the phase transition where asymptotic critical point behavior is clearly dominant. During FY 1997, Barmatz participated in the planning of the ISS LTMPF by serving on the science planning committee. Precision ground-based measurements are now being performed in preparation for MISTE’s science concept review (SCR), scheduled for November 1998.

The Superfluid Universality Experiment (SUE) was chosen in February 1996 to be a flight definition experiment for operation on the ISS. SUE will measure properties of superfluid helium just below the phase transition to determine critical parameters at the transition. These measurements will be repeated at several pressures to test theories of the universality predictions of such transitions. Of critical importance to the success of SUE is the development of high-resolution pressure control capability. Activities in 1997 focused largely on demonstrating and validating this new technology. Last year’s effort also included participation on the science planning team for the ISS LTMPF. The SCR for SUE is scheduled for November 1998. Lipa is the PI for SUE.

Of note in the fundamental physics discipline is the fact that researchers generally must advance the state of the art in technology...
in order to take full advantage of the opportunities offered by the space environment. These advancements in technology can be applied to other endeavors in support of American commerce or in support of the presence of humans in space. Example technologies include superconducting magnetometers for efficient resource mining and noninvasive medical diagnostics; management of cryogenic fluids for life support systems and manufacturing use; and use of highly accurate, low-temperature clocks for navigation, global positioning, and communications.

The second fundamental physics NRA was released in FY 1997, and 86 proposals were received in response. Many of the proposals were for new, innovative research directions in all three subdisciplines. To review the proposals, NASA assembled high-quality panels, including a “blue ribbon” panel with two Nobel laureates. Selection of research for funding is expected in early FY 1998. In addition, two glovebox research proposals were developed and submitted for review last year.

The Fundamental Physics Steering Group, with advice and assistance from other scientists in the ground-based and flight programs, finalized a science plan for the discipline. This plan will be updated on an annual basis to represent a discipline science outlook with about a 5- to 10-year horizon.

A few notable achievements during FY 1997 ground-based investigations are listed below.

- George Seidel, of Brown University, successfully suspended drops of liquid helium using a nonuniform magnetic field. He was able to observe motions of the drops and could control their spin with electric forces after applying charges to the drops. Unusual noncoalescence behavior was observed for two drops in the potential well, which was explained as being due to vapor occurring between the drops to isolate them from each other.

- Horst Meyer, of Duke University, and Guenter Ahlers, of the University of California, Santa Barbara (UCSB), resolved an old discrepancy in the data for the heat flow resistance at the interface between a solid surface and liquid helium. New data at Duke and at UCSB for the boundary-resistance anomaly as the lambda point transition is approached now agree, resolving a difference in earlier results. Rebuilding the experimental cell to eliminate very small gaps was crucial to these measurements.

- Kurt Gibble, of Yale University, has demonstrated the feasibility of critical technologies needed for development of a rubidium-based microgravity clock.

- Dan Heinzen, of the University of Texas, Austin, observed Bose-Einstein condensation in rubidium.

- Robert Chave, of JPL, developed a magnetostrictive valve operating at low temperature with a very small fluid volume. The valve was cycled over 100 times at low temperature. Valve demonstration with a high-temperature, superconducting solenoid was also performed.

- Results from ground-based investigations have been published in 31 presentations, 19 proceeding papers, and 36 articles in refereed journals.

- Fundamental physics investigations have supported 29 students who are working toward their doctoral degrees and 10 undergraduate students. Five graduate students received their doctoral degrees in FY 1997.

Meetings, Awards, and Publications

This year’s Nobel Prize in physics was awarded to three scientists responsible for the development of laser cooling and trapping of atoms. Steve Chu, of Stanford University; William D. Phillips, of the National Institute of Science and Technology; and Claude Cohen-Tannoudji, of École Normale Superieur in France, were recognized for their contribution to the field of laser cooling and trapping. These accomplishments have already led to important developments such as the observation of Bose-Einstein condensation in a dilute gas of atoms and the potential for ultraprecise atomic clocks for ground and space applications. Chu and Phillips have been involved in various capacities in the NASA fundamental physics program during the last few years.

The 1997 Fundamental Physics Investigators Workshop drew 62 attendees to Santa Barbara, California, May 7–9. Several of the investigators reported new findings that raised questions concerning discrepancies with existing theories. One of the more exciting announcements was Heinzen’s report of his group’s verging upon observing Bose-Einstein condensed atoms (Heinzen announced the observation of BEC shortly after the workshop). Rob Duncan, of the University of New Mexico, who is the PI for DYNAMX, presented beautiful new data showing helium in a self-organized state near the lambda transition. Prospects for performing meaningful tests of theories of relativity and gravitation in the STEP investigation were described by Francis Everitt and Saps Buchman, both of Stanford University. Special sessions describing plans for the development of facilities for the ISS brought out the need for investigator input to establish requirements envelopes for these facilities. Mike Devirian, of JPL, described the recent and planned growth in this program and pointed to new opportunities for glovebox experiments and for near-term shuttle flights; two new glovebox experiments were proposed as a result of discussions at the workshop. Mark C. Lee, of NASA headquarters, illustrated the evolution of a program for support by the fundamental physics program of the Human Exploration and Development of Space enterprise, inviting the investigators to contribute to the ideas being advanced. Ahlers presented the science plan for fundamental physics, asking for comments from the investigators to help
refine the concepts described in the document. Proceedings, consisting of summaries of the presentations, will be published as a NASA document.

Several members of the fundamental physics discipline attended the Symposium on Physical Sciences in Microgravity in St. Petersburg, Russia, June 15–21, 1997. This symposium covered a broad area of microgravity science and applications, including combustion science, fluid physics, fundamental physics, and materials science, and was attended by 200–300 scientists and engineers. The symposium provided a valuable opportunity to mingle with people from other microgravity disciplines. Ahlers gave an invited plenary talk (one of only three for the entire meeting). This talk was an opportunity to explain to the broader community the exciting developments in microgravity fundamental physics that are taking place right now. The presentation was received with much interest by our colleagues in the broad microgravity science community.

A workshop on low-temperature microgravity physics was held in Chernogolovka, Russia, June 23–27, 1997. The workshop was organized by the Institute of Solid State Physics of the Russian Academy of Science and was chaired by the institute’s director, Yury Ossipyan. About 50 scientists were in attendance to hear 23 scientific papers presented in the areas of low-temperature condensed matter physics, laser cooling and atomic physics, and gravitational physics by participants from Japan, Russia, the Ukraine, and the United States. Many papers represented scientific results obtained by international teams of researchers.

Six investigators in the fundamental physics program represented NASA. The proceedings of this workshop will be published in the Russian language journal Fizika Nizkikh Temperatur (Low-Temperature Physics).

The Quantum Fluids Workshop, organized by École Normale Supérieure, was held in Paris, France, July 21–25. About 250 international participants, including three Nobel Prize winners, were in attendance. The scientific program included 192 presentations in condensed matter physics and in laser cooling and atomic physics. Six U.S. microgravity fundamental physics investigators attended the meeting, along with 18 additional presenters with strong ties to this microgravity program. The DYNAMX flight project presented preliminary results showing the first measurements of nonlinear thermal conductivity data. Following peer review, the meeting contributions will be published in the *Journal of Low Temperature Physics*.

The Space Cryogenics Workshop, jointly organized by JPL and the University of Oregon Physics Department, was held in Eugene, Oregon, August 4–5. NASA’s Microgravity Research Division and its Office of Space Science jointly sponsored the workshop. At the workshop, the latest developments in space cryogenics were discussed. Following peer review, the workshop contributions will be published in the journal *Cryogenics*.

### Flight Experiments

The Confined Helium Experiment (CHeX), which studies fundamental questions regarding the influence of boundaries on the behavior of matter, completed system integration and testing at JPL about midway through the year and was shipped to Kennedy Space Center (KSC) for launch integration. At KSC, CHeX completed integration verification testing with the Mission Peculiar Experiment Support Structure carrier and was ready for transport to the pad. CHeX was launched on the space shuttle as part of the fourth United States Microgravity Payload (USMP–4) mission on November 19, 1997. Lipa is the PI for CHeX.

The Critical Viscosity Experiment (CVX) successfully flew on the first True Air Speed (TAS–01) payload as part of the 85th Space Transportation System (STS–85) mission in August. The mission was extended by one day to allow the CVX team to collect additional data. The experiment performed exceptionally well and collected data for nearly the entire 11-day mission. The main objective of the CVX experiment was to measure the viscosity of xenon to within 0.3 percent of the critical density and to within 0.6 mK of the critical temperature (Tc), which is 30 times closer than can be measured on Earth. Preliminary analysis of the data suggests that accurate viscosity measurements were obtained to within about 1 mK of Tc, and possibly as close as 0.6 mK. The weak divergence of the viscosity was clearly seen in the microgravity environment and was approximately twice as large as the best measurements on Earth. The divergence is strongly masked in Earth’s gravity due to stratification of the fluid density. Data analysis and manuscript preparations will be continued throughout next year. The PI for CVX is Robert Berg, of the National Institute for Standards and Technology.

The FY 1997 ground and flight tasks for fundamental physics are listed in Table 6. Further details on these tasks may be found in the complementary document *Microgravity Science and Applications Program Tasks and Bibliography for FY 1997*, NASA Technical Memorandum 206645, February 1998.
Table 6  **Fundamental physics tasks funded by the Microgravity Research Division in FY 1997**

Materials Science Overview

The goal of the materials science research program is to establish and improve the quantitative and predictive relationships in the structure, processing, and properties of materials. Production processes for most materials include steps that are very heavily influenced by the force of gravity. Typical gravity-related effects on materials science research include buoyancy-driven convection, sedimentation, and hydrostatic pressure. The opportunity to observe, monitor, and study material production in low gravity promises to increase our fundamental understanding of production processes and their effects on the properties of the materials produced. By careful modeling and experimentation, the mechanisms by which materials are formed can be better understood and can result in improved processing controls. In this way, materials scientists can design new metal alloys, semiconductors, ceramics, glasses, and polymers to improve the performance of a wide range of products, such as complex computers and stronger, more durable metal alloys.

Several important events took place during fiscal year (FY) 1997, such as the successful flights of the Liquid Metal Diffusion (LMD) investigation in January, the first Microgravity Science Laboratory (MSL–1) mission in April, and the relight of the MSL mission (MSL–1R) in July. The materials science program placed an emphasis on ensuring that principal investigators (PIs) conducting flight-based experiments successfully completed the flight definition phase major reviews, including the science concept review (SCR) and the requirements definition review (RDR), in a timely manner through dedicated NASA and PI teams. Also during FY 1997, the materials science program began implementation of NASA’s Human Exploration and Development of Space (HEDS) enterprise Strategic Plan, which includes goals, performance measurements, and metrics. The HEDS Strategic Plan, which has direct benefits for the nation, provides the framework for conducting materials science research.

In the spring, the Committee on Materials Science Research on the International Space Station (ISS) was convened under the auspices of the National Research Council to examine NASA’s research plan for microgravity materials science with respect to evolving interests and priorities in the field of materials science. Additionally, the committee assessed the Space Station Furnace Facility (SSFF) concept with respect to its specific research capabilities, technology, and usefulness to the U.S. materials science community. The committee’s review reconfirmed the value of research conducted in NASA’s materials science program, but recommended that NASA expand the range of experiments and classes of materials (such as glasses, ceramics, and polymers) that the SSFF could accommodate. NASA addressed the council’s concerns by beginning work toward the design of a more flexible flight facility that would accommodate a wider variety of materials investigations and be more compatible with available power, volume, upmass, and crew resources on the ISS. The new concept is known as the Materials Science Research Facility (MSRF). The MSRF consists of independent, modular racks, each of which will be comprised of experiment modules that can be replaced on orbit; module inserts; and investigation-unique apparatus and/or multiuser, generic processing apparatus that will support a wide variety of scientific investigations. The first rack is targeted for the third Utilization Flight (UF–3) to the ISS.

In December 1996, the NASA Research Announcement for materials science was issued. Over 200 proposals were received and reviewed by selection panels. It is anticipated that the selection of flight and ground PIs will be announced in the first quarter of FY 1998. For the flight definition investigations selected from the 1994 research announcement, SCRs are planned for FY 1998, and RDRs are planned for FY 1999.

Meetings, Awards, and Publications

The Scientific and Technological Advisory Council (STAC) met in Huntsville, Alabama, November 10–13, 1997. STAC is the Russian organization responsible for program management and implementation of U.S.-funded Russian space research. The purpose of the conference was to present experiment results. The conference was attended by approximately 60 high-ranking Russian scientists and administrators, many of whom are members of the Russian Academy of Sciences, as well as participants from the Alliance for Microgravity Materials Science and Applications (AMMSA). Among those AMMSA members who gave presentations at the conference were Marc Pusey (co-chair and presenter for the Space Biotechnology session); William Witherow and Alexander Chernov (presenters for the Space Biotechnology session); Iwan Alexander (co-chair and presenter for the Space Technology and Materials Science session); and Donald Gillies, Sandor Leboczky, Ching-Hua Su, and Frank Szofran (presenters for the Space Technology and Materials Science session). Among those AMMSA members who provided general support were Danna McCauley, who coordinated the AMMSA support; Charlie Walker and Leonard Williams, who provided computer support; and Jean George, Nancy Marsh, and Sue Zarger, who provided daily support at the conference’s help tables. A tour of Marshall Space Flight Center (MSFC) was conducted and included stops at the Global Hydrology and Climate Control building, the Space Sciences Laboratory, the Microgravity Development Laboratory, the drop tower, the space station mockups, and the Structural Biotechnology Laboratory. A separate tour was provided of selected facilities at the University of Alabama in Huntsville.

The Society of Photo-Optical Instrumentation Engineers (SPIE) sponsored its second conference on materials research in low gravity at its annual International Symposium on Optical Science, Engineering, and Instrumentation. The symposium took place July 27–August 1, 1997, in San Diego, California. SPIE hopes to hold this conference every two years. The 1997 conference topics included materials for sensors and electronics with special emphasis on crystal growth from the vapor phase, containerless processing of new materials, measurement of properties, and characterization.
and modeling of crystal growth processes. A joint panel discussion on materials processing for detectors and electronics was also held in conjunction with other meetings with similar content at the symposium. The panel discussion outlined the current status of reduced-gravity materials processing and focused on the critical needs and challenges in this area. Researchers drawn from industry, universities, and various NASA centers presented papers in eight sessions and participated in the conference. Narayanan Ramachandran, of the Universities Space Research Association at MSFC, served as conference chairman and editor of the conference proceedings.

**Flight Experiments**

The LMD investigation utilized the Canadian vibration isolation system called the Microgravity Isolation Mount, which is located on the Russian space station, Mir. LMD was launched on the 81st Space Transportation System (STS-81) mission in January 1997 and was operated on Mir during the NASA-4 increment. The technological goals of LMD were to test the diffusion coefficient measurement technique at a single temperature using indium, and to determine how easily these diffusion coefficient measurements are contaminated by convection arising from g-jitter.

Seven materials science experiments were conducted on the MSL–1R mission in July 1997: Coarsening in Solid-Liquid Mixtures (CSLM); Liquid-Phase Sintering-2 (LPS-2); Diffusion Processes in Molten Semiconductors (DPIMS); Experiments on Nucleation in Different Flow Regimes; Alloy Undercooling Experiments; AC Calorimetry and Thermophysical Properties of Bulk, Glass-Forming Metallic Liquids; and Measurement of Surface Tension and Viscosity of Undercooled Liquid Melts.

The objective of the CSLM experiment was to study the coarsening kinetics of tin-rich particles in eutectic liquids of lead-tin alloys with various compositions. This study was conducted in order to gain an understanding of the coarsening process through direct comparison of the results from this experiment with current theories. The experiment was performed in an electric furnace in the shuttle’s Middeck Glovebox.

The purpose of the LPS-2 experiment was to test theories regarding liquid-phase sintering and to examine coalescence and pore behavior during liquid-phase sintering in the microgravity environment. This investigation was conducted in the Japanese Large Isothermal Furnace (LIF), which is a vacuum-heating furnace designed to heat large samples uniformly.

The DPIMS experiment was designed to provide a definitive measurement of the diffusion coefficients of trace impurities such as gallium, silicon, and antimony in molten germanium, and to investigate the dependence of diffusion on temperature, impurity type, and sample diameter. These data will be used to develop models of diffusion. DPIMS was also conducted in the LIF.

The Experiments on Nucleation in Different Flow Regimes investigation was conducted in the German facility called TEMPUS (Electromagnetic Containerless Processing Facility). The purpose of this investigation was to determine quantitatively the temperatures of solid nucleations from melts of pure zirconium and the number of nucleations at each temperature as the melts are cooled below their equilibrium freezing points under laminar and turbulent liquid flow conditions.

Alloy Undercooling Experiments also utilized the TEMTUS facility. The purpose of these experiments was to measure the solidification velocity in steel alloys using a combination of video and pyrometric techniques. These experiments were designed to yield information on phase selection and growth kinetics with limited melt convection. This work has direct application to the design of steel strip casting facilities on Earth and helps scientists understand how welding processes may be conducted in space.

The AC Calorimetry and Thermophysical Properties of Bulk, Glass-Forming Metallic Liquids investigation was conducted in the TEMPUS facility, and its purpose was to measure thermophysical properties of good, glass-forming metallic alloys to allow improvement of process technologies for such materials.

The Measurement of Surface Tension and Viscosity of Undercooled Liquid Metals investigation also utilized the TEMPUS facility. Its purpose was to demonstrate a containerless technique for measuring the viscosity and surface tension of reactive and undercooled liquid metals, such as zirconium; titanium; and metallic, glass-forming alloys.

The Isothermal Dendritic Growth Experiment (IDGE) is a fundamental microgravity materials science investigation that has been flown three times as part of the United States Microgravity Payload (USMP) series. Because virtually all industrially important alloys solidify from a molten state by a dendritic process, a fundamental understanding of dendritic solidification is necessary to correct mathematical models that will provide a basis for improved industrial production techniques. During the first two flights of IDGE on the shuttle, the IDGE flight hardware grew and photographed individual dendrites of the material succinonitrile as they solidified at various temperatures. The third flight of IDGE on USMP–4 will use a different sample material, pivalic acid.

The second flight of the Bismuth-Tin Solidification Experiment in the USMP series will provide data on the solidification behavior and the solid-liquid interface stability of bismuth and bismuth-tin alloys during crystal growth. The experiment uses the Seebeck technique to measure interface undercooling temperature, resistance change across the sample to measure interfacial velocity, Peltier pulsing for demarcation of the sample interface, and quenching to determine the chemistry and structure near the solid/liquid interface. This experiment will be carried out in the French-developed MEPHISTO furnace.

The second flight in the USMP series of the Growth of Solid-Solution Single Crystals experiment, using mercury cadmium telluride in the Advanced Automated Directional Solidification Furnace (AADSIF), will produce material of high scientific value to
the electronics community. It is anticipated that this material will be of benchmark quality and suitable for advanced electrical property measurement. The effects of microgravity and the control of residual amounts of microgravity on crystal growth of materials having high alloy contents will be demonstrated.

The second flight in the USMP series of the Compound Semiconductor Crystal Growth in a Microgravity Environment investigation, using lead tin telluride in the AADSF, will establish some fundamental growth properties of lead tin telluride and a better understanding of the mechanisms involved in crystal growth, especially those affected by gravity. This information will not only help to produce better quality materials on Earth but will also help define future efforts of crystal growth in space and lead the way to an even deeper understanding of the most basic aspects of crystal growth.

The Particle Engulfment and Pushing by Solidifying Interfaces experiment will be conducted in the Middeck Glovebox (MGBX) as part of USMP–4. This investigation will obtain data that will aid in gaining a fundamental understanding of the interaction between the solid-liquid interface of a solidifying material and particles interspersed in the material. Temperature, particle size, and furnace velocity data obtained from this investigation will be used to develop a theoretical basis for processing real-work composite materials.

The Wetting Characteristics of Immiscibles (WCI) experiment will also be conducted in the MGBX as part of USMP–4. The WCI investigation was designed to study ways to control the wetting behavior of immiscible liquids with the walls of their containers in order to produce more desirable structures. Because of the many useful characteristics of “immiscible alloys,” there is great interest in producing combinations where the two liquids are uniformly distributed. When the liquid system can be controlled by processing in a microgravity environment, a better end product can be made.

The FY 1997 ground and flight tasks for materials science are listed in Table 7. Further details on these tasks may be found in the complementary document Microgravity Science and Applications Program Tasks and Bibliography for FY 1997, NASA Technical Memorandum 206645, February 1998.

Acceleration measurement is the process by which knowledge of the microgravity environment is acquired, processed, analyzed, and passed on to the microgravity principal investigators (PIs). The PIs utilize this information during the interpretation of their science experiment results. Measuring the microgravity conditions of a microgravity science experiment is as crucial as measuring the temperature of a thermodynamics experiment. Accelerations (commonly interpreted as vibrations) cause disturbances such as convection, sedimentation, and mixing within microgravity science experiments.

Fluid motion, which is involved in most microgravity experiments, is strongly influenced by accelerations. In materials science experiments, for example, heavier elements, like mercury, tend to settle out of solution with steady accelerations. Hot gases in combustion experiments tend to move due to convection caused by low-frequency accelerations. Fluid movement over a wide range of frequencies may cause drastic temperature changes in low-temperature physics experiments, where the samples are at temperatures close to absolute zero.

The primary objective of the acceleration measurement program is to characterize the reduced-gravity environment of the various experiment carriers, like the space shuttle; the Russian space station, Mir; sounding rockets; and the International Space Station, in order to provide useful information to scientists who conduct their experiments on such carriers. The Space Acceleration Measurement System (SAMS) has flown 18 missions since its first flight on the 40th Space Transportation System (STS-40) in 1991. SAMS units have flown in support of microgravity science experiments in the shuttle middeck, in the Spacelab module, on the Spacelab Mission Peculiar Experiment Support Structure, and in the SPACEHAB module. Experiments from all of the science disciplines have been supported on the shuttle. One SAMS unit was installed on Mir in 1994 and has been operated since then to support U.S. and Russian microgravity science and mechanical structure experiments.

The Orbital Acceleration Research Experiment (OARE) has flown 10 missions since its first flight on STS-40. The OARE instrument measures very low-frequency accelerations.

In fiscal year (FY) 1997, the inaugural mission involving the Space Acceleration Measurement System for Free Flyers (SAMS-FF) was conducted on a sounding rocket flight with a combustion experiment. A SAMS unit has also flown on the DC-9 reduced-gravity airplane to characterize the environment produced during parabolic flight on that facility. The acceleration measurement program has sponsored the flight of two European accelerometer systems to support the Life and Microgravity Spacelab (LMS) and Microgravity Science Laboratory (MSL) missions. The Microgravity Measurement Assembly (MMA), developed by the European Space Agency (ESA), and the Quasi-Steady Acceleration Measurement instrument (QSAM), developed by the German Aerospace Research Establishment (DLR), were flown in FY 1996 and FY 1997.

The acceleration measurement program also works with other microgravity program participants, such as vibration isolation programs, to lend assistance with data processing, interpretation, and analysis. The information collected and produced by this program is available by means of mission summary reports, data files on CD-ROM and Internet file servers, and specialized analysis reports for scientists. Some of the highlights of the FY 1997 acceleration measurement program are discussed below:

- Data resulting from accelerometers aboard the LMS mission (STS-78) were analyzed, and a mission summary report was prepared to summarize the microgravity environment for that mission. The accelerometers aboard this mission were SAMS, OARE, and MMA. Processed and analyzed data were provided to the various experiment teams during and after the mission. A summary report describing the microgravity environment was prepared after the mission and provided to the PI teams and other mission participants.

- Data resulting from the SAMS in the SPACEHAB module on STS-79 during the space shuttle’s docking with Mir were analyzed, and a mission summary report was prepared to summarize the microgravity environment. Processed and analyzed data were provided to the various experiment teams during and after the mission. A summary report describing the microgravity environment was prepared after the mission and provided to the PI teams and other mission participants.

- Data resulting from the SAMS on Mir were analyzed, and summary reports were prepared to characterize the microgravity environment on the station. Processed and analyzed data were provided to the various experiment teams. The acceleration measurement program has cooperated also with Mir’s Structural Dynamics Experiment and the Dynamic Load Sensors experiment.

- MSL–1 (STS-83) and MSL–1R (STS-94) were both supported with accelerometers and data processing and interpretation. The accelerometers aboard these missions were SAMS, OARE, MMA, and QSAM. Real-time data were received, processed, and interpreted during the mission to support the PI teams and their experiment operations. A summary report describing the microgravity environment was prepared after the mission and provided to the PI teams and other mission participants.

- Preparations have continued for the fourth United States Microgravity Payload (USMP–4) mission on STS-87.
On this mission, two SAMS instruments will provide acceleration measurements for four major experiments, and the OARE instrument will provide data about the low-frequency environment of the vehicle. A display on a crew computer will provide feedback about the microgravity environment to the crew.

Meetings

The Sixteenth Microgravity Measurements Group (MGMG) meeting was held in May 1997 at the University of Florida, Gainesville. This meeting was highlighted in an article in Microgravity News, vol. 4, no. 2. The annual MGMG meetings provide a forum for researchers involved in microgravity environment characterization to share the results of their work. The topics at this year’s meeting were experimental results, vibration isolation, acceleration data evaluation, low-level gravity research, and new developments. The attendees this year included participants from space agencies, industry, and academia from Canada, the Czech Republic, France, Germany, Italy, Japan, the Netherlands, Russia, and the United States.

The Accelerations and Countermeasures in the Reduced Gravity Environment session of the 35th American Institute of Aeronautics and Astronautics Aerospace Sciences Meeting was chaired by the acceleration measurement project scientist, Richard Delombard of Lewis Research Center. A panel session was also organized that brought together experts in vibration isolation to describe and discuss aspects of the Suppression of Transient Accelerations By Levitation experiment, the Active Rack Isolation System, and Microgravity Isolation Mount system.

Program personnel co-chaired two residual accelerations sessions at the Joint Xth European and VIth Russian Symposium on Physical Sciences in Microgravity conference in June 1997 in St. Petersburg, Russia.

Flight Experiments

The 17th flight for a SAMS unit took place in the Spacelab module aboard the STS-83 mission as part of the first MSL payload. The OARE instrument was flown in the shuttle cargo bay on that same mission for its ninth flight. Both the SAMS and OARE instruments were again flown on the STS-94 reflight of the MSL payload for their 18th and 10th flights, respectively.
Advanced Technology Development 1997

The Advanced Technology Development (ATD) Program was developed in response to the challenges researchers face when defining experiment requirements and designing associated hardware. Investing in technology development is necessary if the United States intends to remain a top competitor in future scientific research. ATD researchers help ensure that the nation continues its forward strides in the fields of technology development and scientific experimentation.

Technology development projects are designed to address scientific concerns, both focused and broadly based. Focused development projects ensure the availability of technologies that satisfy the science requirement of specific flight- or ground-based programs. Broadly based development projects encompass a long-term, proactive approach to meeting the needs of future projects and missions, such as the human exploration and development of space.

The Microgravity Research Division (MRD) solicits new ATD projects each year and selects the very best for funding. New ATD projects are solicited through a two-step process, for which NASA centers are eligible. First, concept papers are solicited from each NASA center involved in microgravity research. Next, the MRD director and ATD program manager form an ATD Review Panel consisting of microgravity science representatives from each NASA center and from the MRD program at NASA headquarters. The panel reviews concept papers for their technical merit and significance to the microgravity field, and selects candidates for further consideration.

These successful candidates must submit fully detailed ATD proposals. Proposals are peer-reviewed by experts in corresponding technology areas who are selected from non-NASA organizations. Final selections are made based on the panel’s recommendations, which are based on relevance to the anticipated technology needs of the Microgravity Research Program, potential for success, and potential for the project to enable new types of microgravity investigations.

Further details on these tasks may be found in the complementary document Microgravity Science and Applications Program Tasks and Bibliography for FY 1997, NASA Technical Memorandum 206645, February 1998.

Microgravity Technology Development Goals

The ATD Program is intended to provide efficient, cost-effective, and ongoing support for microgravity science investigations. The primary goal of the ATD Program is to develop technology that will enable new types of scientific investigation. This goal is achieved by enhancing the capabilities and quality of experiment hardware available to researchers and by overcoming existing technology-based constraints to microgravity science research capabilities. The ATD Program provides opportunities to carry out the goals of NASA’s Microgravity Research Program by conducting state-of-the-art technology development.

MRD funds technology development through an initial feasibility demonstration that verifies whether or not a technology is suitable for use in either ground-based or flight programs. The goal is to investigate and develop high-risk microgravity research technologies before they are needed on the critical development path for actual flight hardware.

Depending on its state of maturity, the technology developed under the ATD Program may either make a direct transition to use in a specific ground-based or flight program, or require further development to satisfy a specific program requirement. Ideally, the successful progression or completion of an ATD task will reduce risk and cost in the transition from ground-based research to flight hardware design and application in the MRD.

Scope of Projects

Historically, ATD projects have encompassed a broad range of activities. Project funding includes the development of diagnostic instrumentation and measurement techniques, observational instrumentation and data recording methods, acceleration characterization and control techniques, and advanced methodologies associated with hardware design technology.

In fiscal year (FY) 1997, five NASA centers were involved in the MRD ATD Program: Goddard Space Flight Center (GSFC), the Jet Propulsion Laboratory (JPL), Johnson Space Center (JSC), Lewis Research Center (LeRC), and Marshall Space Flight Center (MSFC). The current projects, listed in Table 8, illustrate the breadth of technologies covered by the ATD Program.

### Table 8  Current ATD projects

<table>
<thead>
<tr>
<th>Magnetostrictive Low-Temperature Actuators</th>
<th>Advanced Heat Pipe Technology for Furnace Element Design in Spaceflight Applications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Robert Chave, JPL, Pasadena, California</td>
<td>Donald Gillies, MSFC, Huntsville, Alabama</td>
</tr>
</tbody>
</table>

The objective of this project is to further the development of low-temperature magnetostrictive materials. Reducing the cost and increasing the uniformity of magnetostrictive crystals will enhance potential applications. Future applications could include acoustic pumps for microgravity cryogen transfer or magnetometers that use magnetostrictive crystals as the primary sensor element and fiber optics for readout.

This project focuses on the development of a heat pipe that will operate as an isothermal furnace liner capable of processing materials at temperatures up to 1500°C (400°C higher than existing technology). The isothermality and tight control of the heat pipe will enable materials science experiments to be conducted under more favorable thermal conditions.
Space Bioreactor Bioproduct Recovery System
Steve Gonda, JSC, Houston, Texas

The purpose of this effort is to develop a Bioproduct Recovery System (BRS) that allows the selective removal of molecules of interest from space bioreactors, thus enhancing the productivity of those bioreactors. The BRS will be miniaturized to meet volume and power constraints, and designed to operate in microgravity.

Advanced Diagnostics for Combustion
Paul Greenberg, LeRC, Cleveland, Ohio

The goal of this project is to develop a series of more sophisticated measurement techniques applicable to the general area of microgravity combustion science in order to improve the accuracy and spatial/temporal yield of the data acquired, and to extend the range of applicability and access to the relevant parameters presently inaccessible through current methods.

Manufacturing of Refractory Containment Cartridges
Dick Holmes, MSFC, Huntsville, Alabama

This project focuses on using plasma spray in a low-pressure, inert environment to form containment cartridges to be used for growing crystals of metals, alloys, and semiconductors in microgravity.

Free-Float Trajectory Management
Kirk Logsdon, LeRC, Cleveland, Ohio

The objective of this work is to develop the technology for an extended, consistently reproducible acceleration environment. The stabilized low-gravity phase of the flight trajectory in DC-9 aircraft, specifically for free-float packages. The goals are to extend the free-float time to 10 seconds or longer and to obtain stable accelerations of 0.0001 g or lower in a consistent, reproducible manner.

Passive Free-Vortex Separator
John McQuillen, LeRC, Cleveland, Ohio

The objective of this project is to develop an effective, low-power, two-phase separation system. The system will enable the separation of two-phase flows for reuse during long-term spaceflight.

Laser Light Scattering With Multiple Scattering Suppression
William Meyer, LeRC, Cleveland, Ohio

This project provides a simple and novel optical scheme that overcomes multiple scattering effects in turbid media. In addition, ways to experimentally measure and provide a full analytical solution for double, triple, and higher-order scattering are being developed.

Surface Light Scattering
William Meyer, LeRC, Cleveland, Ohio

This project enables a new way of addressing surface sloshing that will allow the measurement of both surface tension and viscosity for transparent and optically accessible opaque media.

Laser-Feedback Interferometer
Ben Ovryn, LeRC, Cleveland, Ohio

The objectives of this ATD project are to evaluate, adapt, and deliver a novel form of interferometry, based upon laser-feedback techniques, that will provide a robust, versatile, state-of-the-art diagnostic instrument applicable to a wide variety of microgravity fluid physics and transport phenomena. The instrument can be used to measure both temporal and spatial change in optical path length and object reflectivity.

Development of an Electrostrictive Valve
David Pearson, JPL, Pasadena, California

The objectives of this ATD project are to develop a miniature cold valve with no moving parts for use as an active phase separator for liquid helium and to study the ability of a submicron aperture to act as a tunable Josephson junction in 4He.

A Protein Crystal Growth Studies Cell
Marc Pusey, MSFC, Huntsville, Alabama

The primary goal of this project is to design and construct prototype cells and associated systems for the study of the protein crystal growth process. A second goal is to develop practical methods for storing proteins prior to use in crystal growth and other experiments.

High-Resolution Thermometry and Improved SQUID Readout
Peter Shirron, GSFC, Greenbelt, Maryland

The objective of this project is to develop high-resolution thermometers that overcome current problems such as radiation. A high-resolution detection depth thermometer using a two-stage series array superconducting quantum interference device (SQUID) amplifier for readout will be more simple, cost-effective, and sensitive than existing technology.

Application of Superconducting Cavities to Microgravity Research
Don Strayer, JPL, Pasadena, California

This ATD project has two main objectives: (1) to use modern microwave electronics; high quality factor, low-temperature superconducting cavities; and high-resolution temperature control to develop an ultrastable oscillator system that will provide a comparison oscillator for the laser-cooled atomic oscillators now under development in the microgravity research program; and (2) to develop high-temperature superconductor materials, high quality factor cavities, and electronics that can be integrated with a cryocooler to provide an easy-to-use materials characterization system for use on the International Space Station (ISS).

Vibration Isolation and Control System for Small Microgravity Payloads
Mark Whorton, MSFC, Huntsville, Alabama

Laser-induced incandescence (LII) is being developed for microgravity combustion research as a two-dimensional imaging diagnostic for the measurement of soot volume fraction. LII, in conjunction with other optical imaging techniques, provides unparalleled temporal and spatial resolution, yielding insights into soot formation and oxidation processes.

A New Ultrahigh-Resolution Near-Field Microscope for Observation of Protein Crystal Growth
William Witherow, MSFC, Huntsville, Alabama

The primary objective of this ATD project is to build and test a new optical method for observing protein crystals as they nucleate and grow based on a tapered-fiber probe in a near-field scanning optical microscope.
**Microgravity Technology Report**

NASA’s *Microgravity Technology Report* covers technology policies, development, and transfer activities within the Microgravity Research Program from FY 1978 through FY 1997. It also describes the recent major tasks initiated under the ATD Program and identifies current technology requirements. The FY 1997 *Microgravity Technology Report* is available as a companion to this annual MRP report.

**Experiment Hardware for Space Shuttle and Mir Flights**

Significant efforts continued in fiscal year 1997 in preparation of multiuser and experiment-unique apparatus for missions using the space shuttle and the Russian space station, *Mir*. Listed in Table 9 are Space Transportation System (STS) missions with significant microgravity experiments, followed by short descriptions of the U.S.-developed flight experimental apparatus that have been in use and are under development in the Microgravity Research Program to support those missions. A list of flight experiment hardware being developed by international partners that will be used by U.S. investigators appears in Table 10.

* Launch Date Flight Mission Full Name

Middeck and Get Away Special (GAS) microgravity payloads only.

GAS payloads also flew on STS-40, -41, -43, -45, -47, -54, -57, -60, -63, -64, -66, -72, and -77.
Advanced Automated Directional Solidification Furnace: This instrument is a modified Bridgman-Stockbarger furnace for directional solidification and crystal growth. (USMP–2, USMP–3, USMP–4)

Bioreactor Demonstration Unit (BDU): The BDU is a rotating cylinder bioreactor that is supported by subsystems that provide media perfusion and exchange, incubator temperature control, and data storage. It is useful for the investigation of cell science and tissue engineering. (STS-70, Shuttle/Mir–4, Shuttle/Mir–8)

Biotechnology Refrigerator (BTR): The BTR has a refrigerated volume of 0.58 cubic feet with forced air convection. It is programmable with a temperature range of 4° C to 50° C. (Shuttle/Mir–7, Shuttle/Mir–8, Neurolab)

Biotechnology Specimen Temperature Controller (BSTC): BSTC is a programmable cell culture incubator that can be used for flight experiments in cell biology, microbiology, and tissue engineering. The current version has four individually controlled chambers with a temperature range of 4° C to 50° C. (Shuttle/Mir–7, Neurolab)

Biotechnology System: This instrument is composed of a rotating wall vessel bioreactor, a control computer, a fluid supply system, and a refrigerator for sample storage. (Mir)

Combustion Module-1: This module is being developed to perform multiple combustion experiments in orbit; the first two experiments were the Laminar Soot Processes experiment and the Structure of Flameballs at Low Lewis Number experiment. (MSL–1, MSL–1R)

Confined Helium Experiment Apparatus: This apparatus provides a thermometer resolution better than 100 picodegrees in measuring properties of helium samples confined to a two-dimensional state. It flew in the Low-Temperature Platform, where it was used to test finite size effects under controlled conditions to uncover underlying fundamental principles. (USMP–4)

Critical Fluid Light Scattering Experiment Apparatus: This apparatus provides a microkelvin-controlled thermal environment for performing dynamic light scattering and turbidity measurements of room-temperature critical fluids. (USMP–2, USMP–3)

Critical Viscosity of Xenon Experiment Apparatus: This apparatus provides a precision-controlled thermal environment (microkelvin) and an oscillating screen viscometer to perform viscosity measurements of room-temperature critical fluids. (STS-85)

Crystal Growth Furnace: This instrument is a modified Bridgman-Stockbarger furnace for crystal growth from a melt or vapor. (USML–1, USML–2)

Diffusion-Controlled Protein Crystallization Apparatus for Microgravity (DCAM): The DCAM hardware, which was designed for long-duration protein crystal growth on Mir, combines liquid-liquid diffusion and dialysis methods to effect protein crystal growth. Each DCAM tray assembly consists of 27 DCAM experiment chambers containing precipitant solutions and protein sample solutions. (Shuttle/Mir–4, Shuttle/Mir–5, Shuttle/Mir–6)

Drop Physics Module: This apparatus is designed to investigate the surface properties of various suspended liquid drops, to study surface and internal features of drops that are being vibrated and rotated, and to test a new technique for measuring the surface tension between two immiscible fluids. (USML–1, USML–2)

Droplet Combustion Experiment Apparatus: This apparatus is designed to study droplet behavior during combustion by measuring burning rates, extinction phenomena, disruptive burning, and soot production. (MSL–1, MSL–1R)

Gas Supply Module (GSM): The GSM provides a carbon dioxide-enriched air supply for the support of mammalian cell culture in the bioreactors. (Shuttle/Mir–4, Shuttle/Mir–8)

Gaseous Nitrogen (GN2) Dewar Protein Crystal Growth Experiment Apparatus: The GN2 dewar is a device that can maintain samples at cryogenic temperatures for about 13 days. Frozen liquid-liquid diffusion and batch protein crystal growth experiments are launched in a GN2 dewar and then allowed to thaw to initiate the crystallization process in a microgravity environment. The GN2 dewar houses a protein crystal growth insert that typically holds approximately 200 protein samples. (Shuttle/Mir–4, Shuttle/Mir–5, Shuttle/Mir–6)

Geophysical Fluid Flow Cell: This instrument uses electrostatic forces to simulate gravity in a radially symmetric vector field, centrally directed toward the center of the cell. This allows investigators to perform visualizations of thermal convection and other research-related topics in planetary atmospheres and stars. (Spacelab–3, USML–2)

Interferometer for Protein Crystal Growth (IPCG): The IPCG is an apparatus designed to operate in the Mir glovebox to measure details of how protein molecules move through a fluid and then form crystals. IPCG comprises three major systems designed to produce images showing density changes in a fluid as a crystal forms: an interferometer, six fluid assemblies, and a data system. (Shuttle/Mir–7)

Isothermal Dendritic Growth Experiment Apparatus: This apparatus is being used to study the growth of dendritic crystals in transparent materials that simulate the solidification of some aspects of pure metals and metal alloy systems. (USMP–2, USMP–3, USMP–4)
**Lambda Point Experiment Apparatus:** This apparatus provides temperature control in the part-per-billion range of a bulk helium sample near the superfluid transition at 2 K for testing the theory of critical phenomena under well-controlled static conditions. It flew in the Low-Temperature Platform. (USMP–1)

**Low-Temperature Microgravity Physics Cryogenic Dewar:** This apparatus supports different experiments, including the Lambda Point Experiment, the Confined Helium Experiment, and the Critical Dynamics in Microgravity experiment. (USMP–4, MSP–1)

**Low-Temperature Platform:** This apparatus provides a 2 K environment for fundamental physics experiments for up to 12 days on the shuttle. It also provides the mechanical and data interfaces between the experiment and the shuttle carrier. The apparatus supported the Lambda Point Experiment and the Confined Helium Experiment. (USMP–1, USMP–4)

**Mechanics of Granular Materials Experiment Apparatus:** This instrument uses microgravity to gain a quantitative understanding of the mechanical behavior of cohesionless granular materials under very low confining pressures. (Shuttle/Mir–4, Shuttle/Mir–8)

**Microgravity Glovebox:** This is a modified middeck glovebox designed for Mir that will enable the collection of scientific and technological data prior to major investments in the development of more sophisticated scientific instruments. (Mir)

**Microgravity Smoldering Combustion Apparatus:** This apparatus is used to determine the smoldering characteristics of combustible materials in microgravity environments. (STS–69)

**Middeck Glovebox:** The glovebox is a multidisciplinary facility used for small scientific and technological investigations. (USMP–3, USMP–4, MSP–1)

**Orbital Acceleration Research Experiment Apparatus:** This instrument is developed to measure very low-frequency accelerations on orbit such as atmospheric drag and gravity gradient effects. (Multiple missions)

**Physics of Hard Spheres Experiment Apparatus:** This hardware supports an investigation studying the processes associated with liquid-to-solid and crystalline-to-glassy phase transitions. (MSL–1, MSL–1R)

**Pool Boiling Experiment Apparatus:** This apparatus is capable of autonomous operation for initiating, observing, and recording nucleate pool boiling phenomena. (Multiple missions)

**Protein Crystallization Apparatus for Microgravity (PCAM):** The PCAM is used to evaluate the effects of gravity on vapor diffusion protein crystal growth and to produce improved protein crystals in microgravity for determination of molecular structures. Each PCAM cylinder contains 9 crystallization plates, each having 7 sample chambers, for a total of 63 chambers per cylinder. The total number of samples that can be flown in a Single-Locker Thermal Enclosure System unit is 378. (MSL–1, MSL–1R, STS–85)

**Second-Generation Vapor Diffusion Apparatus (VDA-2):** The VDA-2 trays are protein crystal growth devices based on a syringe assembly design to provide mixing of protein and precipitant solutions in microgravity. A mixing chamber (third barrel) has been added to the original double-barreled VDA syringes to improve mixing during activation of vapor diffusion protein crystal growth flight experiments. A Single-Locker Thermal Enclosure System (STES) can accommodate four VDA-2 trays. Each VDA-2 tray has 20 sample chambers, for a total of 80 samples per STES. (MSL–1, MSL–1R, Shuttle/Mir–6)

**Single-Locker Thermal Enclosure System:** The STES replaces a single middeck locker and provides a controlled temperature environment within plus or minus 0.5°C of a set point in the range from 4°C to 40°C. The STES houses a variety of protein crystal growth experiment apparatus, including the PCAM and VDA-2. (MSL–1, MSL–1R, Shuttle/Mir–6)

**Solid Surface Combustion Experiment Apparatus:** This instrument is designed to determine the mechanism of gas-phase flame spread over solid fuel surfaces in the absence of buoyancy-induced or externally imposed gas-phase flow. (Multiple missions)

**Space Acceleration Measurement System (SAMS):** SAMS measures and records the acceleration environment in the space shuttle middeck and cargo bay, in the Spacelab, in SPACEHAB, and on Mir. (Multiple missions)

**Surface Tension-Driven Convection Experiment Apparatus:** This apparatus is designed to provide fundamental knowledge of thermocapillary flows and fluid motion generated by surface tension and temperature gradients along a free surface. (USML–1, USML–2)

**Transitional/Turbulent Gas Jet Diffusion Flames Experiment Apparatus:** This instrument is used to study the role of large-scale flame structures in microgravity transitional gas jet flames. (Get Away Special Experiment)

**Space Station Facilities for Microgravity Research**

The Microgravity Research Program (MRP) continues to develop several multiuser facilities specifically designed for long-duration scientific research aboard the ISS. To obtain an optimal balance between science capabilities, costs, and risks, facility requirements definitions have been aligned with evolving space station capabilities. In total, the MRP has now defined requirements for five multiuser facilities for the ISS:

- Biotechnology Facility (BTF).
- Fluids and Combustion Facility (FCF).
- Low-Temperature Microgravity Physics Facility (LTMPF).
- Materials Science Research Facility (MSRF).
- Microgravity Science Glovebox (MSG).

The BTF will accommodate systems to address cell growth, tissue engineering, protein crystal growth, and fundamental biotechnology research using the microgravity environment and the extended mission time of the space station. In addition, this facility will handle the hardware for new areas of biotechnology research that are being explored. Due to funding limitations, it was decided to use the capabilities of the EXpedite Processing of Experiments to Space Station (EXPRESS) rack facility to handle the needs of biotechnology research during the early phases of the space station. The development of the BTF as a facility dedicated to meet the comprehensive needs of biotechnology researchers has been delayed to a later phase in the space station’s operational life.

The FCF will be a permanent on-orbit facility located inside the U.S. Laboratory Module of the ISS. The FCF will support NASA Human Exploration and Development of Space microgravity program objectives. In particular, the FCF will accommodate and facilitate sustained, systematic microgravity fluid physics and combustion science experimentation on the ISS for the lifetime of the ISS, defined as 10 years with an option to extend to 15 years.

The FCF is being developed predominantly in-house by Lewis Research Center, which also has responsibility for the management of NASA’s microgravity fluid physics and combustion science programs. The FCF capabilities and development schedule have been tightly integrated with the scientific needs and schedules of these programs. As a consequence, the most promising principal investigators (PIs) currently funded by NASA have been scheduled to FCF availability beyond the year 2004 — a PI’s actual flight date will be determined at a later date, based on merit. This integrated approach assures the maximum scientific relevancy and return at the lowest cost.

The FCF held its concept design review (CoDR) in December 1994 and its requirements definition review (RDR)
in October 1996. Since the CoDR, the projected development cost of the FCF has been cut in half while the projected scientific productivity has been more than doubled. Compared to NASA-funded microgravity fluids and combustion experiments on the space shuttle, ISS FCF experiments will cost about one-fifth to one-third as much to build. The FCF requires three on-orbit racks working together to get the necessary economies.

During FY 1997, the RDR hardware concept was substantially revised to allow the three FCF racks to be launched at intervals of approximately one year. In 2001, a Combustion Integrated Rack will be launched, followed by a Fluids Integrated Rack in 2002 and a Shared Accommodations Rack in 2003. At that time, equipment will be moved among the three racks to create the originally envisioned three-rack FCF system, which will perform the full range of fluids and combustion experiments. The FCF project will be operating with a minimal staff through at least 1998.

The LTMPF project combined minimal resources at investigator, industry, and JPL facilities into subteams of adequate size to deliver value-added products in FY 1997. The combined definition team is generating the infrastructure for developing ISS-era instrument requirements through fast prototyping/testing cycles. The test infrastructure, including an instrumented, shakable, cryogenic system, was completed in FY 1997. Development of a laboratory version of the LTMPF electronics controller was started in partnership with Stanford University. A LTMPF CoDR was tentatively scheduled for the end of FY 1998. The Critical Dynamics in Microgravity experiment was added as an LTMPF flight experiment candidate in August 1997, and it is expected that two additional flight definition investigations may be selected from 1996 NASA Research Announcement proposals.

The MSRF is designed to support the current and evolving group of U.S. peer-selected investigations. It will provide the facilities for satisfying near-term and long-range materials science program goals and objectives in a microgravity environment on the ISS. The MSRF consists of a multiple array of modular Materials Science Research Racks (MSRRs) designed to accommodate investigations in basic materials research, applications, and studies of phenomena involved in solidification of metals and crystal growth studies of various semiconductor materials. These investigations require sustained, systematic research and development to identify and characterize the effects of reduced gravity.

The modular racks will support materials science investigations in the U.S. Laboratory Module of the ISS. Each MSRR is a stand-alone, autonomous rack and will be comprised of experiment modules that can be replaced on orbit; module inserts; and investigation-unique apparatus and/or multieuse, generic processing apparatus that will support a wide variety of scientific investigations. The first MSRR (MSRR-1) planned for the ISS is being developed collaboratively by NASA and ESA, and is scheduled for launch on UF–3 in late 2001.

The NASA/ESA accommodations will occupy up to half of a rack, with the remainder of the rack dedicated to NASA. Inserts will house the sample or sample cartridge, will contain heating elements, and can be changed out on orbit. They are envisioned for Bridgman-type crystal growth, isothermal applications, and a variety of other experiments. MSRR-2 and subsequent racks will satisfy investigations that have specific or unique facility requirements that cannot be satisfied with an insert.

The NASA/ESA accommodations definition is in Phase B, with Phase B completion planned for February 1998. An international Materials Science Workshop was held October 13–14, 1997, in Rome, Italy. The workshop provided a forum to continue dialogue between international partners on cooperative development and sharing of research facilities.

The MSG is a multidisciplinary facility for small, low-cost, rapid-response scientific and technological investigations in the areas of biotechnology, combustion science, fluid physics, fundamental physics, and materials science, allowing preliminary data to be collected and analyzed prior to any major investment in sophisticated scientific and technological instrumentation. Negotiations with ESA have been completed for the provision of the MSG by ESA in exchange for early access to ISS capabilities. The MSG completed its preliminary design review in April 1997, and will begin the critical design review process in January 1998. Deployment of the MSG to the ISS is tentatively planned for UF–2 in March 2000.

**Ground-Based Microgravity Research Support Facilities**

During FY 1997, NASA continued to maintain very productive reduced-gravity research ground facilities that include a drop tower, a drop tube, DC-9 and KC-135 parabolic flight aircraft, the Zero Gravity Facility, and several other facilities in support of the MRP. These facilities provide a unique and critical infrastructure necessary for the execution of the many flight- and ground-based investigations and experiments discussed in this report. The reduced-gravity facilities at LeRC have supported numerous investigations addressing various processes and phenomena in several research disciplines for the past 30 years. LeRC’s drop tower and a DC-9 aircraft are able to provide a low-gravity environment (gravitational levels that range from 0.01 of Earth’s gravitational acceleration to 0.0001 of that measured at the Earth’s surface) for brief periods of time. “Zero gravity,” or near weightlessness, also known as microgravity, can be created in these facilities by executing a freefall or semi-freefall condition where the force of gravity on an object is offset by its linear acceleration during a “fall” (a drop in a tower or a parabolic maneuver by an aircraft). The low-gravity environment obtained “on the ground” in the NASA facilities is similar to that of a spacecraft in an orbit around the Earth. Even though ground-based facilities offer relatively short experiment times of a few to 20 seconds, this available test time has been found to be sufficient to advance the scientific understanding of many phenomena. Also, many experiments scheduled to fly on sounding rockets, the fleet of space shuttles,
Space Station Mir, and the International Space Station are tested and validated in the ground facilities prior to testing in space. Experimental studies in a low-gravity environment can provide new discoveries and advance the fundamental understanding of science. Many tests performed in the NASA facilities, particularly in the disciplines of combustion science and fluid physics, have resulted in exciting findings that are documented in a large body of literature.

The LeRC facilities host scientists and engineers, both domestic and foreign, from universities and government agencies. Typically, on an annual basis, well over 100 microgravity experiments are supported by these unique national resources. The following information highlights the accomplishments of these facilities in FY 1997.

Able to accommodate several experiments during a single flight, LeRC’s DC-9 aircraft represents the largest ground-based, reduced-gravity platform. Low-gravity conditions of approximately 20 seconds can be obtained by flying a parabolic trajectory that includes a rapid climb at about 55–60 degrees, a slow pushover at the top of the climb, and a descent angle of about 30–40 degrees. During the course of this maneuver, an altitude change of approximately 6000 feet is experienced. Over 50 of these maneuvers can be performed on a single flight.

The DC-9 continued to play a key role in microgravity research in FY 1997. The aircraft flew 73 flights with 3,313 trajectories accomplished in 180 flight hours. Thirty-eight investigations were supported, many of which flew multiple times. Some of the key highlights included astronaut crew training for several experiments that flew on MSL–1 and MSL–1R. Also, the president of the CSA, William Evans; and the Canadian Minister of Industry, John Manly, participated in research flights that had CSA-sponsored experiments on board. These milestones were all reached prior to July 21, at which time the DC-9 was eliminated from the microgravity program. Future reduced-gravity aircraft flights will be performed on JSC’s KC-135 aircraft. Six to 12 flight campaigns will be conducted out of LeRC every year with this aircraft. In FY 1997, four experiments were performed during 223 trajectories over 10.9 flight hours.

The LeRC 2.2-Second Drop Tower obviously offers a shorter test time than the DC-9 or KC-135, but its simple mode of operation and capability of performing several tests per day make it an attractive and highly utilized test facility, particularly for performing evaluation and feasibility tests. Over 16,000 tests have been performed in the drop tower to date. During FY 1997, as in the past several years, drop tests averaged about 100 per month.

Reduced-gravity conditions in the drop towers are created by dropping an experiment in an enclosure, known as a drag shield, to isolate the test hardware from aerodynamic drag during a 24-m freefall in the open environment. Over 30 experiments were supported during the 1,200 drops performed in FY 1997. As in the past, several of these experiments were in support of the development of space shuttle experiments. The steady utilization of the drop tower is expected to continue as many new experiments are in the design and fabrication phases of development for the coming years.

The Zero Gravity Research Facility at LeRC, a registered U.S. national landmark, provides a quiescent low-gravity environment for a test duration of 5.18 seconds as experiments are dropped in a vacuum chamber that goes 132 m underground. Aerodynamic drag on the freely falling experiment is nearly eliminated by dropping in a vacuum. This procedure restricts drop tests to two per day, resulting in fewer projects supported in this facility. However, the relatively long test time and excellent low-gravity conditions more than compensate for the lower test throughput rate. In FY 1997, seven major projects were supported as 130 test drops were executed.

The Drop Tube Facility, located at MSFC, consists of sections of a 26-cm diameter stainless steel pipe vertically assembled into a tube of 105 m in length. Completely evacuated of air, the tube can produce freefall periods of 4.6 seconds. Vacuum levels of less than a billionth of an atmosphere are achievable. The drop tube is especially useful for high-temperature material processing assays, as well as experiments in droplet dynamics and engineering tests such as the ones designed to yield results for the Tethered Satellite Mission. In FY 1997, six experiments were supported during 351 drops.

Table 11 summarizes activities at ground-based microgravity research facilities in FY 1997.

Table 11 Use of ground-based low-gravity facilities in FY 1997

The LeRC 2.2-Second Drop Tower obviously offers a shorter test time than the DC-9 or KC-135, but its simple mode of operation and capability of performing several tests per day make it an attractive and highly utilized test facility, particularly for performing evaluation and feasibility tests. Over 16,000 tests have been performed in the drop tower to date. During FY 1997, as in the past several years, drop tests averaged about 100 per month.

Reduced-gravity conditions in the drop towers are created by dropping an experiment in an enclosure, known as a drag shield, to isolate the test hardware from aerodynamic drag during a 24-m freefall in the open environment. Over 30 experiments were supported during the 1,200 drops performed in FY 1997. As in the past, several of these experiments were in support of the development of space shuttle experiments. The steady utilization of the drop tower is expected to continue as many new experiments are in the design and fabrication phases of development for the coming years.

The Zero Gravity Research Facility at LeRC, a registered U.S. national landmark, provides a quiescent low-gravity environment for a test duration of 5.18 seconds as experiments are dropped in a vacuum chamber that goes 132 m underground. Aerodynamic drag on the freely falling experiment is nearly eliminated by dropping in a vacuum. This procedure restricts drop tests to two per day, resulting in fewer projects supported in this facility. However, the relatively long test time and excellent low-gravity conditions more than compensate for the lower test throughput rate. In FY 1997, seven major projects were supported as 130 test drops were executed.

The Drop Tube Facility, located at MSFC, consists of sections of a 26-cm diameter stainless steel pipe vertically assembled into a tube of 105 m in length. Completely evacuated of air, the tube can produce freefall periods of 4.6 seconds. Vacuum levels of less than a billionth of an atmosphere are achievable. The drop tube is especially useful for high-temperature material processing assays, as well as experiments in droplet dynamics and engineering tests such as the ones designed to yield results for the Tethered Satellite Mission. In FY 1997, six experiments were supported during 351 drops.

Table 11 summarizes activities at ground-based microgravity research facilities in FY 1997.
Once again, thousands of elementary and secondary school teachers attended the 1997 annual meetings of the National Science Teachers Association, the National Council of Teacher’s of Mathematics, and the International Technology Education Association. These educational meetings and conferences provide NASA with the opportunity to demonstrate new ways to improve student understanding of the effects of normal and low gravity and the implications of microgravity research. Over 10,000 each of microgravity science educational posters, teacher’s guides, mathematics briefs, reduced-gravity demonstrator manuals, microgravity mission lithographs, and other supplementary materials were distributed at the conferences. The number of teachers requesting to be added to the microgravity education and outreach mailing list was 1,483, compared to 1,200 last year. With these new additions, the total number of K–12 teachers on the mailing list is 3,321 (726 kindergarten and elementary, 826 middle school, 1,473 high school, and 296 other educators.)

The microgravity research centers — the Jet Propulsion Laboratory (JPL), Lewis Research Center (LeRC), and Marshall Space Flight Center (MSFC) — also participated in various regional and national outreach/educational and media activities. These activities included open houses at JPL and MSFC, where over 10,000 citizens at each location visited the centers and laboratories to learn, through demonstrations provided by microgravity scientists and engineers, about the microgravity research being conducted; the Apple MacWorld Conference, where data acquisition software was used on a Macintosh computer to demonstrate how an experimental procedure can be controlled and data can be acquired and displayed remotely using the Internet; television/radio interviews by local and national networks during the first Microgravity Science Laboratory (MSL–1) mission in July 1997; newspaper and talk show interviews, including appearances on “Good Morning America” and “The Phil Donahue Show”; a tour of a Ford Motor Company plant, where researchers from LeRC spoke with attendees of the American Institute of Aeronautics and Astronautics conference about engineering issues; creation of videos and web sites highlighting microgravity research; cooperative educational activities with programs such as the Caltech Precollege Science Initiative (CAPSI), which helped to develop a middle school science module; and hosting high school students who were winners of the Space Science Student Involvement Program competition.

The Microgravity Research Program’s (MRP’s) quarterly newsletter, Microgravity News, continues to reach thousands of K–12 teachers, curriculum supervisors, science writers, university faculty, graduate students, scientists and principal investigators, and technology developers. Distribution for each newsletter has reached an all-time high of 9,082 copies, which is an increase of 275 percent. In addition to individuals receiving the Microgravity News, distribution to public and private associations, corporations, laboratories, and education resource centers continues to grow. Microgravity News features articles on experiment results, shuttle missions, science and technology developments, research funding opportunities, meetings, collaborations, and microgravity science researchers.

From a national pool of 35 applicants, 7 graduate students were selected to receive support for ground-based microgravity research during 1997–1998 under the Graduate Student Research Program (GSRP). These selections were made from a pool of applicants who submitted their research proposals to NASA headquarters. Each of the microgravity research centers also selects graduate students who will conduct a portion of their research at a NASA research facility. All selections were based on a competitive evaluation of academic qualifications, proposed research plans, and the students’ projected use of NASA and/or other research facilities. The new selections for 1997–1998 have brought the number of GSRP researchers to 20. When added to the graduate students working with NASA-funded PIs, the number of graduate students directly employed in microgravity research now totals 748.

The MRP’s World Wide Web (WWW) Home Page continues to provide regular updates on upcoming conferences, microgravity-related research announcements, enhanced links to microgravity research centers, educational links, and links to microgravity science photo/image archives. A list of important microgravity WWW Internet addresses is presented in Table 12.

The JPL fundamental physics team has remained actively engaged in reaching out to explain and demonstrate the microgravity program to the community. The following examples illustrate the many ways in which the team continues to demonstrate a strong commitment to making microgravity research available and relevant through public outreach, educational involvement, and cross-discipline participation.

The Microgravity Scaling Theory Experiment (MISTE) project, headed by Principal Investigator Martin Barmatz, of JPL, participated in the Apple MacWorld Conference in San Francisco, California, January 7–10, 1997. Labview data acquisition software was used on a Macintosh computer to demonstrate how an experimental procedure can be controlled and data can be acquired and displayed remotely using the Internet. The MISTE project also had a booth at the conference where a poster was displayed and handouts were given to the public describing this NASA low-temperature microgravity fundamental physics experiment. The attendance at MacWorld was approximately 70,000 people. The demonstrations proved to be very good examples of public outreach and demonstrated JPL’s use of advanced technology. Senior Apple executives also witnessed the demonstrations and actively participated in controlling the experiment. The conference attendees who saw the demonstrations were favorably impressed. The MISTE team is following up this conference presentation and producing technology development agreements with National Instruments, the company that markets the Labview software, as the industrial partner.

JPL introduced students to science by bringing middle school, high school, and college students into its laboratories. A middle school honor class toured the low-temperature physics lab building, and the students and teachers were shown demonstrations of cryogenic phenomena. The students also visited research sites,
where the goals of several investigations were described by JPL scientists.

Members of the Low-Temperature Science and Engineering group (LTSE) at JPL remain actively involved in outreach activities. During the past year, several of the group members have taken cryogenic demonstration kits into grade school classrooms to show students the behavior of materials at low temperatures. The LTSE group participated in the JPL Open House in June, and plans are presently being devised for participation in the Los Angeles County Fair in September.

A new educational activity began this year in cooperation with the CAPSI program to develop a middle school science module. Since our research program explores gravity-related physical phenomena, the first module will describe how gravity affects the behavior of fluids. Scientists from JPL will work with middle school teachers to develop materials that the students will use in an inquiry-based learning method. Larry Wade is to be commended for his initiative in contacting the CAPSI organization to begin this educational pursuit.

The LTSE group also hosted seven college students and one high school student as summer hires in JPL labs this past summer. The students worked on computer programs using the Labview operating system, on designing hardware and lab space organization, and on building magnetostrictive devices for cryogenic applications. One Caltech student will continue his association with fundamental physics through a senior thesis studying limits of time system coordination with various techniques, such as the Global Positioning System.

### Microgravity Data Archiving

MSFC maintains the Microgravity Science Data Archive, which houses video, photographic, digital, and other data products generated during microgravity biotechnology and materials science experiments. Information concerning these experiments and their data products is contained in approximately 75 Experiment Data Management Plans (EDMPs). In addition to the EDMPs, further information concerning microgravity experiments in all microgravity science disciplines resides in the Microgravity Research Experiments (MICREX) database, which currently contains over 900 experiment records. In the future it will be possible to search the MICREX database and the European Space Agency’s (ESA’s) Microgravity Database simultaneously. In addition, there are plans to add other international partner databases to allow access to all existing microgravity databases.

The MSFC photo archive contains approximately 4,500 photographs. In FY 1997, a subset of over 200 of these images was digitized and made available through the Microgravity Research Program WWW site at [http://microgravity.msfc.nasa.gov](http://microgravity.msfc.nasa.gov). Over 350 videotapes and 16-mm films are cataloged in the MSFC video archive.

LeRC has been actively building its archive collection in the areas of combustion science and fluid physics. Currently, there are over 710 combustion science papers and over 435 fluid physics papers in the archive; a listing of the papers by author, along with abstracts from the papers, is available at [http://www.lerc.nasa.gov/WWW/MCFEP](http://www.lerc.nasa.gov/WWW/MCFEP). In FY 1997, abstracts of the papers continued to be added to the LeRC WWW site. The experiments database currently consists of information from a number of recent experiments, along with data from a few earlier missions. This information is contained in an EDMP database and includes such items as an experiment description; a list of publications associated with the experiment; a summary of experiment results and data; and a listing of videos, photos, and digital data. In FY 1997, archivists continued gathering data on fluids and combustion experiments from missions prior to the first United States Microgravity Laboratory (USML–1). They also began gathering data from missions after USML–1. Several of the EDMPs are available on the LeRC web site. The EDMPs for all fluid physics and combustion science experiments flown will continue to be collected and added to the LeRC web site in FY 1998. Photographs from the experiments will also be added to the database during FY 1998.

Funding for the Microgravity Research Program (MRP) in fiscal year (FY) 1997 totaled $134.3 million. This budget supported a variety of activities, including an extensive microgravity research and analysis program; development and flight of microgravity shuttle and sounding rocket missions; International Space Station (ISS) planning, technology, and hardware development; and educational outreach. The funding distribution for combined flight and ground efforts in the various microgravity research disciplines is illustrated in Figure 1.

The MRP operates through four NASA field centers. Figure 3 illustrates the funding distribution among these centers (and includes NASA headquarters funding for the Microgravity Research Division). The MRP science discipline authority and major responsibilities are as follows:

- Jet Propulsion Laboratory — fundamental physics.
- Johnson Space Center — cell and tissue culture portion of the biotechnology discipline.
- Lewis Research Center — combustion science, fluid physics, and microgravity measurement and analysis.
- Marshall Space Flight Center — biotechnology, materials science, and the glovebox program.

Technology development tasks were also funded at each of the NASA field centers in FY 1997.
NASA’s goal is to improve the quality of life on Earth by using ground- and space-based research to promote new scientific and technological discoveries. The Microgravity Research Program plays a vital role in our nation’s economic and general health by carefully selecting, funding, and supporting scientists across the country. It also serves as an important link in the international endeavors that are the hallmark of America’s space program, which is conducting business better, cheaper, and faster through cooperative ventures and other streamlined practices.

By disseminating knowledge and transferring technology among private industries, universities, and other government agencies, NASA’s Microgravity Research Program continues to build on a foundation of professional success, evidenced by the number of publications and conferences attended, while reaching out to encompass the populace at large. Educational outreach and technology transfer are among the program’s top goals, making the benefits of NASA’s research available to the American public. Space shuttle and Mir research missions, as well as experiments performed in short-duration microgravity facilities, are yielding new understanding about our world and the universe around us, while paving the way for long-duration microgravity science on the International Space Station.
