A Thesis submitted to the Graduate School
in partial fulfillment of the requirements
for the Degree
Master of Science in Electrical Engineering
Major Subject: Electrical Engineering

New Mexico State University
Las Cruces, New Mexico
August 1999
“Carrier Estimation Using Classic Spectral Estimation Techniques for the Proposed Demand Assignment Multiple Access Service,” a thesis prepared by Bradley James Scaife in partial fulfillment of the requirements for the degree, Master of Science, has been approved and accepted by the following:

Timothy J. Pettibone
Dean of the Graduate School

Phillip L. De León
Chair of the Examining Committee

Date
July 5, 1999

Committee in charge:

Dr. Phillip L. De León, Chair
Dr. Gerald J. Dunn
Dr. Stephen Horan
Dr. James P. Le Blanc
ACKNOWLEDGMENTS

The author would like to take the opportunity to thank Frank Hartman, Cliff Baxtor, and the entire White Sands Complex Staff for their support and for the opportunity to gather test data in a very busy environment. Additionally, the author wishes to express gratitude to Lawrence Alvarez for invaluable assistance on numerous occasions in setting up hardware and test beds.

The author would like to thank Dr. Paul Klipsch for his incredible service to New Mexico State University, the field of electrical engineering, and to the author personally. It was an honor to be a graduate scholarship recipient but a greater honor to meet Dr. Klipsch personally.

The author would like to express his appreciation and admiration for the professors of the Klipsch School of Electrical Engineering and in particular to Dr. James Le Blanc for excellent instruction and invaluable assistance with this work.

The author would like to take the opportunity to express a lifetime of gratitude for the many lessons taught him by his advisor Dr. Phillip L. De León. His work on this project and support of it as well as his willingness to direct, correct, and instruct with seemingly endless patience has made him more friend than advisor.

A final word of gratitude to my wife Nancy for ever demonstrating faith, hope, and love, but the greatest of these....
VITA

Dr. Phillip L. De León, Chair

In any satellite communication, the Doppler shift associated with the satellite’s position and velocity must be calculated in order to determine the carrier frequency. If the satellite state vector is unknown then some estimate must be formed of the Doppler-shifted carrier frequency. One elementary technique is to examine the signal spectrum and base the estimate on the dominant spectral component. If, however, the carrier is spread (as in most satellite communications) this technique may fail unless the chip rate-to-data rate ratio (processing gain) associated with the carrier is small.
In this case, there may be enough spectral energy to allow peak detection against a noise background.

In this thesis, we present a method to estimate the frequency (without knowledge of the Doppler shift) of a spread-spectrum carrier assuming a small processing gain and binary-phase shift keying (BPSK) modulation. Our method relies on an averaged discrete Fourier transform along with peak detection on spectral match filtered data. We provide theory and simulation results indicating the accuracy of this method. In addition, we will describe an all-digital hardware design based around a Motorola DSP56303 and high-speed A/D which implements this technique in real-time. The hardware design is to be used in NMSU’s implementation of NASA’s demand assignment, multiple access (DAMA) service.

1 Overview

1.1 Introduction

In an effort to provide increased access to NASA's Space Network (SN), a Demand Access Multiple Assignment communication scheme has been proposed. Under this scheme, users would have the option to communicate short information packets at low data rates on demand. This scheme is driven by the increased ability of modern satellites (spacecraft) to detect error conditions on board the satellite [1]. Under current SN operations, communication services are pre-scheduled and the schedules often have significant delay and are not easily modified. The DAMA service is to be designed such that it operates independently of the current scheduled Multiple Access (MA) service.

The SN consists of geostationary Tracking and Data Relay Satellites (TDRS) that operate as a virtual "radio frequency (RF) mirror" for data transmissions from/to low Earth orbiting (LEO) spacecraft communicating to/from ground stations. These LEO spacecraft are in orbit about the earth and due to their relative motion to a receiving TDRS, a Doppler shift is induced in transmissions. Since the MA service is pre-scheduled, these Doppler shifts may be accounted for allowing the ground station to detect and receive the LEO signal. In the case of the DAMA system, where data transmissions are to be scheduled on demand,
the Doppler shift information may be unknown and thus a system must be designed to estimate (to within ±3 kHz) the carrier of the LEO signals.

1.2 Comparison of Goddard and NMSU's DAMA Proposals

Two independent proposals have been offered to implement the DAMA service. The first has been proposed by NASA/Goddard Space Flight Center (GSF) and the second by New Mexico State University. The Goddard proposal intends to provide continuous tracking of all LEO satellites equipped with DAMA capability. Thus with the state vectors of all of these LEO satellites known, the Doppler shift of the carrier can be computed much like for the MA service. Whereas the Goddard proposal must maintain these state vectors so that the ground station receiver may demodulate, the NMSU proposal forgoes LEO satellite state vector knowledge to simplify the required ground station hardware. In the NMSU proposal only a single element of the TDRS antenna array is used as a global beacon [1]. With a global beacon configuration, even a satellite that is experiencing alignment problems may transmit an emergency message to ground station users utilizing the DAMA communication system. As the state vector of the communicating spacecraft has been given up, the ground station will not know the position of transmitting LEO space vehicle and thus the Doppler shift cannot be accounted for [2]. Previous work has shown that the Doppler shift of a LEO spacecraft and
a TDRSS can vary by as much as ±50 kHz which is outside of the ground station receiver (GSR) tolerance of ±3 kHz [3].

The fundamental problem to NMSU’s proposal lies with estimating the carrier of the transmitted signal to within the tolerance of the GSR. Hardware must be developed that will provide a locking tone, accurate to within the ground station tolerance, in order for the ground station to demodulate. The problem is exacerbated by the nature of the DAMA signal. The DAMA carrier is to employ a Spread Spectrum (SS) scheme. SS signals tend to suppress spectral peaks of carriers and have responses that are spread out over a wider bandwidth. As we shall show below, this makes the proposed solution to carrier estimation more difficult.

1.3 Proposed Solution

The proposed solution to the carrier estimation problem described above is to employ classical Digital Signal Processing (DSP) spectral estimation techniques to estimate the carrier frequency. We shall employ a Discrete Fourier Transform (DFT) to generate magnitude squared spectral data from the received signal. The resolution of the DFT will be set to provide accuracy to within the ground station tolerance. A single iteration of this process will not be sufficient to protect the carrier estimation from noise so we will average the magnitude squared data to limit the effects of noise. This process results in a *periodogram*. Having obtained the
periodogram of the received signal, we shall employ a frequency domain matched filter to maximize the Spectrum-to-Noise ratio (SPNR). The frequency domain matched filter will be predetermined based primarily upon the predefined SS frequency characteristics, such as processing gain (PG) and power, of the received signal. The results of the application of the matched filter, like those of the time domain equivalent, provide an optimal solution by enhancing the spectrum prior to searching. We then search the enhanced periodogram for a peak with which we base our carrier estimation. The accuracy of this technique will be shown to depend primarily on the PG of the DAMA carrier and the Signal-to-Noise ratio (SNR).

1.4 Simulations, Test Data, and Theory

At the core of the proof of concept for the proposed solution is a simulation model designed in Matlab. The simulation models the DAMA carrier against additive white Gaussian noise (AWGN), where we use AWGN to effectively model the white noise like spectrum of the MA service [2]. Having approximated the TDRSS channel by its most critical feature (presence of the MA service) we add the DAMA carrier and simulate carrier estimation based upon the approach described in section 1.3. The simulation model provides estimation accuracy as a function of the SNR and the PG of the DAMA carrier. We will show that accurate estimation,
to within the ground station tolerance, is achievable 80%-90% of the time for the
given DAMA data rates and corresponding spreading rates.

To verify the accuracy of the simulation model, we include the results of an
experiment with test data gathered at NASA’s White Sands Complex (WSC). In
this experiment, actual data vectors were streamed to a ground station transmitter
for transmission to a TDRS (in orbit) and sent back to the ground station receiver.
The parameters of the experiment were set such that we could observe several
key issues with carrier estimation. The data gathered was processed with the
proposed algorithm and compared to simulation results. The most significant
conclusion of the experiment was that carrier estimation with the collected data
was nearly equivalent to results obtained through simulation. The simulation is
then recognized to accurately model the actual TDRSS channel.

We have developed a theoretical analysis that leads to a rough approximation
for carrier estimation accuracy. The analysis of carrier frequency estimation is
based upon use of the DFT, and the description of carrier estimation accuracy as
a random variable [4]. From this description and the use of various approxima-
tions, we obtain an expression that describes the root mean square error (RMSE)
between the actual carrier frequency and the estimate. The result is expressed as
a function of SNR, data (chip) rate, and window type and length. Though the
approximations break down in low SNR cases, in the higher SNR cases theory
agrees with simulation results.
1.5 DAMA Hardware

As described above, we seek to provide the ground station with an accurate carrier frequency based upon our estimation. We perform this estimation through the use of specifically designed hardware. The base of the hardware utilizes Motorola's DSP56303EVM (EVM). The EVM utilizes Motorola's DSP56300 core which is capable of 80 million instructions per second at 80 MHz and has enough available on-chip memory to implement the algorithm described above. As we will be required to sample the incoming signals at rates greater than that allowed by the EVM, we have integrated an 800 kHz 12 bit Burr-Brown ADS7810/19 analog to digital converter (A/D) into the design. To interface the EVM and the A/D requires some additional logic and level translators that are implemented on an additional interface card. The card allows the EVM to control the A/D while allowing samples from the A/D to be passed directly into the memory of the EVM for processing. These three components, excluding some additional analog pre-processing and post-processing equipment, make up the core of the carrier estimation hardware. The hardware is designed to receive signals that have been filtered and frequency shifted to baseband, estimate the carrier, and then provide a locking tone to the GSR. The GSR will use this carrier estimate to demodulate the DAMA carrier.
The hardware has been tested with synthesized waveforms as well as actual waveforms captured during the WSC experiment and performs as designed/required.
2 DAMA Project Description

2.1 Current WSC Operations

TDRSS was originally devised by NASA as an efficient means to control costs associated with providing a ground station for each satellite [5]. The concept of a space network was formed where users could transmit and receive all communications through a common ground station. NASA operates TDRSS as a space network (SN) using it to provide customers with communication access to their Low Earth Orbiting (LEO) spacecraft. The SN consists of six geostationary Tracking and Data Relay Satellites (TDRS) located 22,250 miles in orbit and a ground station located at the WSC (other operational ground stations exist as well) [5]. The function of a TDRS is to act as a virtual "RF mirror" through which communication signals are relayed between user spacecraft and the ground station. An antenna array, located on each TDRS, is tuned by weighting antenna elements to provide a spot beacon to the spacecraft. This requires a unique weighting vector and associated signal processing equipment for each user spacecraft [1]. Two communication schemes are used by the SN to fulfill various communication needs [5] [3]:

- multiple access (MA) at low data rates of 100 bps to 50 kbps operating in the S-band (2.1031 GHz - 2.1097 GHz forward service, 2.2845 GHz - 2.2905 GHz return) and using CDMA spread spectrum with a chip rate of 3 Mchips/s.
single access (SA) at up to 300 kbps operating in either the S-band or the K-band (2.0204 GHz - 2.1233 GHz forward service, 2.2 GHz - 2.3GHz return) using TDMA.

The SN is able to provide 80% - 100% coverage for LEO spacecraft and is capable of simultaneously supporting 26 user spacecraft.

TDRSS consists of geostationary satellites but the LEO spacecraft that use this system are not necessarily geostationary. We know that signals originating from a source moving relative to a TDRS will experience a Doppler shift [6]. It has been shown that the Doppler shift of these signals can be as much as ±50 kHz [3]. This is illustrated in Figure 2.1. The GSR normally maintains the state vector of
the satellite it is intended to communicate with and hence can simply calculate an estimate of the Doppler shift. Provided that the estimated Doppler shift is within ±3 kHz of the actual Doppler shift, the ground station can demodulate the received signal. In any system where one would forgo knowledge of the state vector of these satellites, the result would be that in general the GSR could not synchronize to the Doppler shifted carrier and thus the carrier need be estimated.

The SN currently works under a scheduling process whereby a request for service must be made in advance (prescheduling) to utilize the SN. The scheduling delay often takes as much as 21 days for the request to be processed [3]. While the request can be serviced quicker in emergencies, the delay does not allow customers to react in near real-time to emergency situations that may arise with a user spacecraft. DAMA is a proposal that seeks to provide on demand communications between a user and their spacecraft without the need for prescheduling.

2.2 NMSU’s Proposal

The initial scope of the NMSU proposal is towards implementing a “911” service where satellites that have an gone into an error state may communicate this to the user when it detects such a condition. The eventual scope is to provide this service as a standard service to all DAMA capable spacecraft that require only low data rates with small data packets. Additionally it must be expanded to allow multiple access—or use by multiple users. For this thesis we assume a
single DAMA user at a time. The algorithm to be developed below is scalable to allow for multiple DAMA users at some point in the future.

The NASA GSFC proposal seeks to implement the DAMA service by maintaining the state vector information for each user spacecraft that is DAMA capable by continuously tracking each of these spacecraft. As in the MA service, with the state vector of the spacecraft known, it is routine to estimate the Doppler-shifted carrier and provide this estimate to the GSR. In contrast, NMSU’s proposal gives up this state vector knowledge so that the DAMA ground station equipment is simplified. This leads to a problem with the Doppler estimation as it now must be estimated and supplied by means other than from the state vector. We propose a solution to this problem with the algorithm to be developed below that will execute on the hardware that was also developed to provide the GSR with this Doppler estimate. DAMA is to be implemented with a SS BPSK modulated communication scheme like the MA service described above. However, there are certain restrictions that determine the parameters of the scheme. The DAMA carrier is to be placed just inside the first upper TDRSS null as observed in Figure 2.2. The carrier will be placed such that a maximal Doppler shift of +50 kHz will not place the carrier too near the null so that the rolloff of the TDRSS channel and other associated GSR equipment, which bandpass filters on the mainlobe, will not adversely affect carrier estimation. The signal in Figure 2.3 consists of the MA service and the DAMA signal and demonstrates the overall response of
the TDRSS system with the addition of the DAMA signal. We furthermore see the effects of sidelobe rejection of the TDRSS system.

2.3 Spread Spectrum Fundamentals

To discuss the operational parameters of the proposed DAMA carrier estimation, it will first be necessary to provide some fundamentals of SS communication schemes and definitions of important parameters. These parameters directly affect carrier estimation performance.

We begin with a basic and widely used definition for SS systems: SS systems are distinguished by the characteristic that their signals consume a bandwidth greater than the information rate [7]. Though there are several different tech-
techniques for implementing the spreading, we focus on the technique known as spread spectrum by direct sequence (DS). DS spread systems implement a scheme where the information data is acted upon by pseudo-noise (PN) data, whose elements are referred to as chips, to produce a spread spectrum bandwidth (BW). The ratio of chips to bits is typically an integer and the chip rate is often much higher than the data rate. This ratio is defined as the processing gain (PG) where

\[ PG = \frac{R_c}{R_b} \]  

(2.1)

and \( R_c \) is the chip rate in chips/s and \( R_b \) is the data rate in bits per second (bps). The PG also describes the ratio of chips/bit from which we see that each bit will be acted upon by PG chips through the use of modulo-2 addition. The PN code

Figure 2.3: TDRSS MA Spectrum at IF from Actual Data
sequence, $C_i$, has the property that it approximates a white noise sequence and is periodic. $C_i$ is designed purposely such that

\[ C_i^T C_j = \delta(i - j) \]  

indicating orthogonality between PN codes of equal length but different “keys”. In practice, PN codes are only approximately orthogonal. The number of 1’s and 0’s, with $C_i \in \{0, 1\}$, differ by at most one. Many different techniques exist for the generation of these codes and we provide the 2047 PN code as an example. Though the 2047 PN code exhibits the qualities of white noise it is in fact periodic with period 2047. This PN code may be viewed as a primitive polynomial and implemented with a shift register as seen in Figure 2.4.

In general the initial state of the shift register is a “key” and each key represents a different PN code that is orthogonal to other PN codes as described in (2.2). In this manner each PN code operates as an orthogonal basis function for each vector.
of data. Multiple users are allowed in the same bandwidth precisely because each message is orthogonal to the other.

For the MA service, $R_c = 3$ Mchips/s. From theory it is known that the BW consumed by this modulation scheme follows the relation:

\[ BW \propto 2R_c \] (2.3)

where $BW$ is the bandwidth, and $R_c$ is the chip or spreading rate [8]. From (2.3) we observe that the MA service will occupy approximately 6 MHz of BW as is illustrated in Figure 2.2 and Figure 2.3.

We will show that PG plays a large role in carrier estimation but first it is useful to see how PG will affect the BW of a signal. As we “spread” a carrier more and more (increase $R_c$ relative to $R_b$), the spectrum of the carrier will tend to spread out and flatten. This can be observed in Figure 2.5 below where we have spread a BPSK at various rates. Both PG's in Figure 2.5 are relatively low however, it will be shown that low PG's are required for accurate carrier estimation. Estimation of the carrier becomes more difficult at higher PGs since the carrier power is not concentrated over a small band of frequencies, which would result in a sharp
Figure 2.5: Spreading Effect of Processing Gains

spectral peak, but rather distributed over a wider range. The peak in the SS case has less power and therefore noise may bury it (as intended for SS systems).

2.4 Operating Parameters Description

We now describe some of the communication parameters of the DAMA proposal. We are particularly interested in three parameters when dealing with digital communication systems: power, bit rate, and probability of bit error. For DAMA carrier estimation, we are not required to demodulate the signal and thus do not look at the probability of bit error. The first two, however, will affect our ability to perform carrier estimation.
For the purposes of this thesis, we will describe DAMA power in two different ways. The first will be SNR in $dB$ of the DAMA carrier-to-MA spectrum. We use this SNR definition when observing simulated work since the MA spectrum was modeled as AWGN. We can gain insight into this definition by observing Figure 2.3. The DAMA carrier will exhibit a peak against the passband of the MA service. Thus, we are interested in the DAMA power to that flat passband. The second way of describing power will be as the ratio $C_b/N_o$ which is used in WSC operations. This is a measure of DAMA carrier power to the noise floor. Through observations of spectra (under typical conditions) collected at WCS, the mapping between the two power ratios was seen to be approximately

$$C_b/N_o = 45dB \approx SNR = 2dB.$$  \hspace{1cm} (2.4)

In this thesis, we shall use $C_b/N_o$ to describe results of actual signals and SNR when describing simulation results. To avoid confusion when comparing the two, we shall map SNR to $C_b/N_o$.

Since we intend DAMA to be a SS BPSK system, we must not only describe data rates, but also chip rates and therefore PGs. Due to the nature of the DAMA service, it has been proposed that $R_b = 1$ kbps [3]. The PG, as defined in (2.1), will be another parameter that is of primary concern since it determines the BW of the DAMA carrier and impacts the sampling rate. DAMA carrier estimation
accuracy will be shown to depend on PG to a large extent and therefore the chip rate will be a matter of investigation.

Sampling rate is another important parameter. It was initially proposed that the PG would be set to \( PG = 100 \) [3]. With the data rate set as above, this implies a chip rate, \( R_c = 100 \) kbps. This will exhibit a mainlobe width of 200 kHz by (2.3). From Figure 2.2 we can observe that we will need to account for another 100 kHz due to Doppler shift. The total possible BW of the DAMA carrier is then 300 kHz. We recall that to avoid aliasing while sampling the DAMA carrier, the DAMA signal must be bandlimited and be sampled at

\[
f_s \geq 600 \text{kHz}.
\]

A commonly available, inexpensive 800 kHz A/D was found that matched the requirements and we thus chose \( f_s = 800 \) kHz. This has implementation ramifications that will be discussed below.

2.5 Carrier Estimation Problem

The problem with demodulating the DAMA carrier is the same as that for the MA carrier (though for the MA case the estimate is derived from the state vector of the satellite): the ground station is not capable of demodulating a signal if the error of the estimate is greater than ±3 kHz from the actual. As NMSU's proposal will not keep track of state vector information for each user spacecraft, the carrier must be estimated reliably and efficiently and then passed to the ground station.
receiver. NMSU's DAMA proposal hinges upon accurate carrier estimation. We have developed an algorithm and hardware that performs this task and we shall describe the algorithm as well as the parameters for operation that will provide accurate carrier estimation. The hardware will provide a locking tone to the ground station receiver.

2.6 Proposed Solution

The proposed solution relies on classical spectral estimation theory with some modifications to improve performance. We begin by assuming that external analog hardware required to bandlimit and frequency shift to baseband the TDRSS and DAMA signals is available. Contained in the 400 kHz band (assuming $f_s = 800$ kHz) will be a portion of the TDRSS signal along with the entire DAMA signal.

We next employ an averaged DFT (implemented with an FFT) which, if mag-squared values are computed, is also known as a periodogram. Since we assume AWGN with zero mean, the averaging has the effect of reducing estimation error variance of the carrier based on the DFT estimate of the DAMA spectrum. We express this as

$$X(k) = \frac{1}{P} \left\{ \sum_{p=1}^{P} \left[ \sum_{n=0}^{N-1} x[n + pN] e^{-\frac{j2\pi kn}{N}} \right]^2 \right\}$$  \hspace{1cm} (2.6)$$

where $P$ is the number of blocks in the average, $N$ is the number of points in the block, $n$ is the sample index, and $k$ is the frequency index [9]. To obtain a frequency resolution that will enable us to estimate within the accuracy of the
GSR, we choose
\[ N = \frac{f_s}{\Delta f} = \frac{800kHz}{3kHz} \approx 267 \] (2.7)
but this would not allow us to use the \textit{radix-2} based FFT. We alternatively round to \( N = 512 \) for use with the FFT which yields
\[ \Delta f = \frac{f_s}{N} = \frac{800kHz}{512} = 1562.5Hz \] (2.8)
This increases our physical resolution beyond what is actually required.

From the result of the periodogram, we are left with an estimate of the spectrum of the received signal. We estimate the carrier frequency by choosing the maxima of the periodogram. We assume that we are operating the DAMA service such that a peak will be observed in the average. We can improve the \textit{spectrum-to-noise ratio} by utilizing a method from communication theory. It is known that the optimal solution for a receiver corrupted by AWGN is obtained by implementing a matched filter [7]. We will employ the frequency domain equivalent, spectral matched filter (SMF), which like its time domain analog is optimal and will maximize the SNR. In the time domain, a matched filter can be described by its impulse response
\[ h(t) = s(T - t) \] (2.9)
with
\[ 0 \leq t < T \]
where $s(t)$ is the time reversed equivalent of the received signal. The matched filter is then convolved with the received signal yielding

$$y(t) = \int_0^t s(\tau)s(T - t + \tau)d\tau. \quad (2.10)$$

The same approach may be applied in the frequency domain where we have a SMF that is matched to the expected, frequency-reversed Power Spectral Density (PSD) of the DAMA carrier. Through a discrete convolution between the SMF and estimated DAMA spectrum, we may arrive at a desired optimal solution that maximizes the spectrum-to-noise ratio. The SMF is described as

$$H(k) = X(N - k) , \quad 0 \leq k < N \quad (2.11)$$

where $X(N - k)$ is the frequency-reversed equivalent of the PSD of the DAMA carrier. The SMF is then convolved with the spectrum of the received signal as

$$X_{smf} = X * H \quad (2.12)$$

where $*$ indicates the convolution operator. The results of applying the SMF to the process will be described in detail in section three. We then form our carrier estimate with

$$\hat{f} = \arg \max \left( \frac{X_{smf}}{N} \right) f_s \quad (2.13)$$

where $\hat{f}$ is the estimated frequency of the carrier, $N$ is the number of points of the FFT and $f_s$ is the sampling frequency. The discrete convolution in (2.12) smears
the number of points by

\[ L_{X_{smf}} = L_H + M \]  \hspace{1cm} (2.14)

where \( L_{X_{smf}} \) is the translated length of \( X_{smf} \), \( L_H \) is the length of the SMF (\( N = 512 \)), and \( M \) is the length of the periodogram (\( N = 512 \)). We must subtract the maxima of the SMF, purposely located at \( N/2 - 256 \), from the index obtained by \( \text{arg max}(X_{smf}) \). The SMF is generated in practice by generating a simulated DAMA carrier (without noise) with random data and averaging 1000 periodograms based on the simulated signal. The simulated signal is set with the PG that we wish to test. A flowchart that describes the algorithm is shown in Figure 2.6.
Figure 2.6: Flowchart for Carrier Estimation Algorithm
3 Theory and Simulation

3.1 Signal Description

We have previously stated that the DAMA carrier will use SS BPSK and we begin with a description of the communication scheme. BPSK is a communication scheme where data is encoded into the phase of a sinusoid (carrier). The general equation for $M$-ary PSK is shown in (3.1)

\[ s(t) = A \cos(\omega_c t + \psi_m(t)) \]  

where $A$ is the amplitude of the carrier, $\omega_c$ is the carrier frequency and $\psi_m(t)$ is the phase component. In general we may add more power to the sinusoid by increasing $A$ but we assume $A = 1$ for the purposes of this thesis. $\psi_m(t)$ may take on $m$ distinct phases based upon the mapping of data to phase. For the binary case we use two distinct phases. Though we could choose any two distinct phases, in order to minimize error we typically choose the antipodal signaling as seen in Figure 3.1 as it provides the optimal decision boundary [8]. With this configuration, the phase term $\psi(t)$ may take on values corresponding to $\psi(t) \in \{0, \pi\}$. This is equivalent to modulating the sign of the sinusoid such that we may revise (3.1) to

\[ s(t) = A d(t) \cos(\omega_c t) \]  

where $d(t) \in \{-1, 1\}$ and is dependent on the mapping of data. As explained in Section 2.3, the data is DS spread by a PN code. For purposes of the analysis that
follows, we may look at SS BPSK as just BPSK at a higher data rate, namely the chip rate. We make this assumption since we are interested only in searching for a spectral peak of magnitude-squared data and not in demodulating the signal.

3.2 Estimation Accuracy Theory

The following arguments follow closely the work of Boaz Porat in his book, A Course in Digital Signal Processing. We have only extended his arguments to frequency estimation of a BPSK signal [4].

To begin, we make the following assumptions: \( s(n) \) is a BPSK signal as described in (3.2), \( S(e^{j\omega n}) \) is the DTFT of \( s(n) \), \( w(n) \) is the rectangular windowing function, and \( v(n) \) is AWGN of zero mean. The received signal would then be

\[
x(n) = s(n)w(n) + v(n)w(n)
\]

taking the Fourier Transform of this yields

\[
X(e^{j\omega n}) = \sum_{n=0}^{N-1} s(n)w(n)e^{-j\omega n} + \sum_{n=0}^{N-1} v(n)w(n)e^{-j\omega n}
\]
The PSD of $s(n)$ is given by [8]

$$P_s(e^{j\omega}) = E \left[ S^2 (e^{j\omega}) \right] = \frac{A^2}{4R} \left[ \text{sinc} \left( \frac{\omega - \omega_c \text{osf}}{2\pi} \right) \right]^2$$  \hspace{1cm} (3.3)

where we have transformed (3.3) from continuous time to discrete time, $R$ is the data rate in bits/sec, and osf is the oversample factor in samples/bit. The maxima of the sinc function as well as the maxima of the BPSK periodogram will occur at $\omega = \omega_c$ hence

$$X(e^{j\omega})|_{\omega = \omega_c} = S(e^{j\omega_c}) + \sum_{n=0}^{N-1} v(n)w(n)e^{j\omega_c n}$$  \hspace{1cm} (3.4)

and taking the magnitude-squared of both sides,

$$|X(\omega_c)|^2 = \left( S(e^{j\omega_c}) + \sum_{n=0}^{N-1} v(n)w(n)e^{-j\omega_c n} \right)\left( S(e^{j\omega_c}) + \sum_{n=0}^{N-1} v(n)w(n)e^{-j\omega_c n} \right)^*$$

$$= \left( S(e^{j\omega_c}) + \sum_{n=0}^{N-1} v(n)w(n)e^{-j\omega_c n} \right)\left( S^*(e^{j\omega_c}) + \sum_{n=0}^{N-1} v(n)w(n)e^{j\omega_c n} \right)$$

$$= |S(e^{j\omega_c})|^2 + 2\Re \left[ S(e^{j\omega_c}) \sum_{n=0}^{N-1} v(n)w(n)e^{-j\omega_c n} \right]$$

$$+ \sum_{n=0}^{N-1} \sum_{m=0}^{N-1} w(n)v(n)w(m)v(m)e^{-j\omega_c(n-m)}$$

Taking the expectation of the magnitude-squared value yields,

$$E[|X(\omega_c)|^2] = E \left[ |S(e^{j\omega_c})|^2 \right]$$

26
The first term is by definition as provided in (3.3) and is evaluated as

$$P_s(e^{j\omega c}) = \frac{A^2}{4R}$$

The middle term evaluates to 0 since we have assumed \(E[v(n)] = 0\). We further assume \(E[v(n)v(m)] = \gamma v \delta(n-m)\), then

$$E[|X(\omega_c)|^2] = \frac{A^2}{4R} + \sum_{n=0}^{N-1} \sum_{m=0}^{N-1} w(n)w(m) \gamma v \delta(n-m)e^{-j\omega c(n-m)}$$

$$= \frac{A^2}{4R} + \gamma v \sum_{n=0}^{N-1} w^2(n)$$

$$= \frac{A^2}{4R} + \gamma v N$$

We next define an output SNR using (3.7) as the ratio between

$$SNR_O = \frac{A^2}{4R \gamma v N} \quad (3.5)$$

We define the input SNR as

$$SNR_I = \frac{A^2}{2 \gamma v} \quad (3.6)$$
where $A^2/2$ is the average power of a BPSK signal [8]. We delineate between output and input SNR to account for the application of the window function. Finally we define a window processing gain as

$$W_g = \frac{SNR_O}{SNR_i \frac{1}{2} N}$$  \hspace{1cm} (3.7)

$$= 2 \left[ \frac{A^2}{N} \frac{\gamma_v}{4R\gamma_v N \frac{A^2}{2}} \right]$$  \hspace{1cm} (3.8)

$$= \frac{1}{RN^2}$$  \hspace{1cm} (3.9)

We next employ a rule of thumb which states

$$\frac{NA^2W_g}{\gamma_v} \geq 100$$  \hspace{1cm} (3.10)

which is given in Porat as a requirement for the reliable detection and frequency estimation of a real sinusoid in noise [4]. We modify (3.10) for the BPSK case in terms of (3.5), (3.6), and (3.9) which yields

$$\frac{A^2}{RN\gamma_v} \geq 100$$  \hspace{1cm} (3.11)

In the development provided by Porat, the mean square error is then given as

$$E[\hat{f}_c - f_c]^2 \approx \frac{24N_oJ_w}{(2\pi)^2A^2D^3}$$  \hspace{1cm} (3.12)

where $N_o$ is the power density of the noise, $J_w$ is a window parameter [4], $D$ is the measurement interval ($D = NT_s$, where $T_s$ is the sampling period), and $A$ is the amplitude of the sinusoid. We further make the assumption that $E[\hat{f}_c - f_c] = 0.$
With this assumption and provided that (3.10) is true, the approximation in (3.12) is valid [4]. The approximation given in (3.12) can now be modified to yield

\[ E[\hat{f}_c - f_c]^2 \approx \frac{24N_\omega \omega}{(2\pi)^2 \frac{A^2}{4R} D^3} \]  

(3.13)

where we have applied (3.3) evaluated at \( \omega = \omega_c \). The result of (3.13) is an approximation of the mean square error (MSE) of the BPSK carrier frequency estimate. We note that like the sinusoid in noise case, the approximation in (3.13) is only valid when we ensure that (3.11) is true.

Equation (3.13) provides an approximation for the expected value of the MSE frequency estimate. We can use it to provide an approximation of the error in estimated frequency \( \hat{f}_c \) from a true frequency \( f_c \) from using a DFT approach to estimation. It is recognized that with the many assumptions and the inclusion of a rule of thumb that (3.13) can only give a rough approximation to the actual MSE of the frequency estimation [4].

### 3.3 Comparison of Theory to Simulation

Having obtained the MSE, we now show how (3.13) compares to simulation data. In the simulation we modeled a BPSK signal with a carrier frequency, \( f_c \), of 178 kHz (typical of DAMA) and the sampling frequency, \( f_s \), set to 800 kHz (as in DAMA). The simulation performed an \( N = 512 \) point DFT on the BPSK signal and measured the MSE of the estimated frequency, \( \hat{f}_c \), to the actual frequency \( f_c \).

The results of the simulation are shown in Figure 3.2 where we have shown the
Figure 3.2: Comparison of Theoretical Curve Against Simulation

simulation results versus the approximation developed in (3.13). The root mean square error (RMSE) is simply the square root of (3.13) and it is the expected value in Hz that \( \hat{f}_c \) is from \( f_c \) as a function of SNR. This relates directly to the accuracy of estimating \( f_c \) with \( \hat{f}_c \) to within the GSR tolerance and provides a means by which we can approximately determine the accuracy for a given SNR.

We can conclude from the simulation that at high SNR’s (< 5 dB), the theoretical curve and the simulation curve match, while at low SNR’s the theoretical curve becomes invalid (due to assumptions made during calculation) [4]. We further conclude that at high SNR’s (3.13) will provide a good estimate of the mean of the estimation accuracy and allow us to predict performance. At low
SNR's the simulation curve approaches a condition where the noise is dominating the spectrum and the maximum peak is uniformly distributed over the 400 kHz band, yielding near random estimates. The theoretical curve is asymptotic to zero RMSE whereas the simulation curve will actually converge only to the difference between the true frequency and the selected DFT frequency—the difference is unlikely to be zero. This illustrates an important point regarding accuracy of carrier estimation: since we quantize to the DFT frequency points, there will most likely be an error irrespective of what SNR we are operating at. The maximum amount of this error assuming large SNR is given by

$$\max(f_c - \hat{f}_c) < \frac{f_s}{N}$$

(3.14)

This error can only be reduced by increasing $N$, the number of points of the DFT.

### 3.4 Simulation Model Description

Though we have developed a theoretical analysis culminating in (3.13), the approximation is not tight enough to provide proof of concept. We turn to a Matlab simulation model to provide a core proof of concept. We shall use this simulation model to explore the operational parameters of the algorithm. The simulation models the DAMA carrier against other MA users and AWGN. The simulation builds up a SS BPSK digital waveform based on the PG that we wish to test and then adds appropriate AWGN. It then estimates the doppler-shifted carrier frequency based upon the algorithm developed in section two. A record is
kept of carrier frequency estimations and those that fall within the tolerance of
the ground station at WSC are counted as an accurate estimation. Likewise any
estimation that is outside of the ground station tolerance is considered inaccurate.
By performing the simulation 10,000 times for each SNR and desired PG, we
obtain a plot that describes estimation accuracy.

The simulation was originally written without the SMF and then rewritten to
include the SMF process. The SMF improves estimation accuracy and allows for
higher PG’s. The Matlab code for the simulation is given in Appendix A.

3.5 Simulation Results

We now provide results of simulation both in the SMF and non-SMF cases.
The simulation results for the non-SMF are shown in Figure 3.3 and illustrate
estimation accuracy as a ratio of accurate estimations to total estimations versus
SNR. In Figure 3.3, we plot three curves for PG = 10, 20, and 100. The curves
are generated through 10000 estimates per SNR and we perform 8 DFT blocks of
N = 512 points. At an SNR = 2 dB, the results of Figure 3.3 demonstrate that
estimation accuracy would be approximately 14%, 60%, and 88% for PG = 10, 20,
and 100 respectively. NASA has placed the requirement that any implementation
should have as high a PG as possible. From Figure 3.3 it is clear that only the PG = 10 case is practical.

Carrier frequency estimation may also be observed through the use of histograms which also relate information regarding the variance of the estimations. In Figure 3.4, Figure 3.5, and Figure 3.6 we show histograms for PG = 10, 20, and 100 respectively. Each is shown for SNR = 2. In each figure the actual carrier frequency is denoted by the center dashed line while the GSR tolerance (±3 kHz) is shown by the outer dashed lines.

The results with the SMF enhancement, as described in section two, are much better (Figure 3.7). The results shown in Figure 3.7 are generated as in the
Figure 3.4: Non-SMF Frequency Estimation for PG = 10, SNR = 2 dB

Figure 3.5: Non-SMF Frequency Estimation for PG = 20, SNR = 2 dB
Figure 3.6: Non-SMF Frequency Estimation for PG = 100, SNR = 2 dB

Figure 3.7: Family of Curves for SMF Case
Figure 3.8: SMF Frequency Estimation for PG = 10, SNR = 2 dB

non-SMF case with the exception that we have now included SMF processing. In Figure 3.7, we show estimation accuracy curves for PG = 10, 40, and 100. Here we see that estimation accuracy of the PG = 100 case has improved seven-fold. The case of PG = 40, a likely DAMA operating parameter, demonstrates accuracy at nearly 90% in a typical operating SNR region. As in the non-SMF case, we observe the histograms of Figure 3.8, Figure 3.9, and Figure 3.10 which are shown for PG = 10, 40, and 100 respectively. Each figure is shown at SNR = 2. From these figures it is clear that there is less variance and therefore more estimations within the GSR tolerance.
Figure 3.9: SMF Frequency Estimation for $PG = 40$, $SNR = 2$ dB

Figure 3.10: SMF Frequency Estimation for $PG = 100$, $SNR = 2$ dB
3.6 Theoretical/Simulation Data Summary

We have demonstrated results for a model that attempts to simulate DAMA carrier estimation in the presence of the TDRSS spectrum which is modeled with AWGN. We provide results indicating that accurate carrier estimation is possible with the algorithm developed in section two. Additionally, we have determined some operating points for the PG parameter. We have shown that we can accurately estimate the DAMA carrier 90% of the time with a $PG = 40$ at the typical SNR range. The simulation has provided a demonstration and we offer a loose theoretical approximation (3.13) to the estimation accuracy. In section four, we shall use data collected at NASA’s White Sands Complex (WSC) to further validate the simulation results.

Appendix A includes all of the developed code for the simulation model including instructions for its use. Additional code is provided to perform data visualization.
4 WSC Data Collection Experiment

4.1 Motivation of WSC Data Collection Experiment

An experiment was devised to perform validation of the simulation model by collecting actual signals transmitted through TDRSS and collected at WSC. We subsequently processed them offline using the estimation algorithm. The fundamental idea of this experiment is that we can observe the performance of the algorithm with actual DAMA signals. If the algorithm using actual signal data performs similar to the simulation under various PGs and at various SNRs, we may state with a degree of certainty that the simulation model is indeed accurate enough to predict carrier estimation. This also allows for the prediction of the performance of the algorithm if any of the operating parameters need to be changed. A side benefit is that we may also perform in-house testing using simulated signals without the expense of interrupting critical TDRSS operations for testing.

This section discusses the actual experiment performed at WSC, including details regarding setup, the processing of the data, and the conclusions drawn. We verify the simulation model's results with actual TDRSS data. Additionally, the experiment points out the realistic operating boundaries which are an important part of the DAMA design.
4.2 Data Collection Setup

Two sets of equipment were used to collect test signals that were sent from the ground station and relayed off of a TDRS back to the ground station. The setup was as shown in Figure 4.1. The Transmit (Tx) equipment consisted of a computer equipped with a high speed PDMA32 Data Transfer Card (PDMA32). The purpose of the Tx equipment was to send a data vector to ground station equipment where it was BPSK modulated and transmitted to a TDRS. The data vector sent consisted of underlying data bits of \{±1\} with \(R_b = 1\) kbps which was then spread by a spreading vector at a rate of \(R_c = PG \cdot R_b\) chips/s. Several of these data vectors, consisting of raw binary data and DS spread with a PN code (see section two), were generated in advance of the experiment and then used as a data source. The source code (wsands.m, wsands2.m, wsands3.m, and wsands4.m) is given in Appendix A.
The Receive (Rx) equipment consisted mainly of a LeCroy Digital Storage Oscilloscope (DSO) to capture IF signals and another computer to store captured signals. As the TDRSS channel is bandlimited to approximately 40 MHz, the DSO was set to sample at a rate of 100 MHz. This was the closest value to the Nyquist rate that the DSO was capable of sampling at. The DSO was capable of storing the captured data waveforms with either 50,000 samples or 100,000 samples depending on the storage medium that was used and both sizes were collected.

With the hardware setup described, we now turn out attention to the test set. The test set was established to test a variety of key parameters and determine the operational bounds of each. The key parameters are

- Processing Gain
- DAMA Carrier power-to-noise ratio \( (C_b/N_0) \)
- Placement of IF Carrier Frequency against TDRSS spectrum

The PG, defined in (2.1), is the most critical of the three. Initial work with the PG indicated a PG of 100 could be used [3]. Subsequent simulations indicated that at this PG value the estimation accuracy was not reliable and lower values were investigated (see section three). It was included in the test set for completeness. PG’s of 10, 20, 40, and 100 chips per bit were the focus of the test set.
Three different carrier power-to-noise ratios were investigated. These ratios were 40, 45, 50 dB. These values were chosen as typical values based upon the experience of WSC staff [10]. It should be noted again that these values are described as a ratio of the carrier power to the noise floor in dB and not carrier power to MA spectrum as described in section three.

The last test parameter is that of the carrier placement. The carrier frequencies were chosen such that a range of frequencies near the TDRSS null could be examined. Recall from section two that we intend to place the DAMA carrier at 2.29 GHz which at IF is 2.9 MHz above the TDRSS center frequency. The range of test frequencies are observed in Figure 4.2. By examining a range of IF frequencies, we are allowed to effectively simulate a Doppler shift as well as examine the effects of the rolloff of the TDRSS channel. Comparing this to the TDRSS spectrum shown in Figure 2.2, we see that the upper range will be affected by the TDRSS rolloff. The full test set is shown in Table 1. The full test set had to be reduced for logistical reasons to lessen impact on TDRSS operations, however, the reduced test set provides enough insight for simulation verification.

### 4.3 WSC Collected Data Processing

We noted above that the captured waveforms were sampled at 100 MHz and stored as either 50,000 or 100,000 length vectors. In section two it was also noted that the bandwidth of the DAMA carrier plus maximum possible Doppler shift yielded a 300 kHz frequency search space and that the FFT resolution will be $1562.5 \text{ Hz}$. Downsampling the captured waveforms to $f_s = 800 \text{ kHz}$ was impractical due to the problems of designing a narrow band decimation filter sharp enough for the rate conversion. Instead we seek a solution that will allow us to perform a frequency search with a nearly equivalent FFT resolution. We see then that

\[
\Delta f_{\text{experiment}} = \frac{f_s}{N} = \frac{100 \text{ MHz}}{65536} = 1525.8 \text{ Hz} \tag{4.1}
\]

provides a nearly equivalent FFT resolution to (2.8). In order to provide the
resolution in (4.1) and maximize the use of the short data sets, the vectors were either overlapped in the 100,000 sample case or zero-padded in the 50,000 length case. Without zero-padding the 50,000 length vector to 65536, the DFT does not meet the required resolution. The net result of this operation is a collection of 65536 length vectors with which to work with. These vectors were then used in a periodogram of eight data blocks chosen at random and processed with the simulation code that was used with a synthetic waveform (see Appendix A). This process was iterated 500 times, due to maximum data support, to form simulation bounds using WSC data.

4.4 WSC Data Results Compared to Simulation

The results of the processed data in comparison to simulation results are shown in Figure 4.3 below. The plot shown is for \( PG = 10 \) with the simulation represented by the curve and the individual data points being the collected data across the various frequencies indicated. The plot indicates successful carrier estimation to within ±3 kHz as the ratio of accurate estimates to total estimates versus \( C_b/N_0 \). We can make several observations from the plot.

The first observation we can make is in regards to carrier power \( C_b/N_0 \). We observe that at a \( C_b/N_0 = 40 \) dB, the estimation accuracy is much less than the simulation exhibits indicating a practical limit to \( C_b/N_0 \). As \( C_b/N_0 \) increases to 45 and 50 \( C_b/N_0 \), estimates performed with actual WSC signal data match
those using synthetic data. This result indicates that we can estimate Doppler accurately provided that the carrier power is high enough for the range of carrier frequencies specified in Figure 4.2. This is an intuitive result as well since we would fully expect that a carrier with higher power will exhibit a more defined peak against the TDRSS spectrum. We also observe that the nominal carrier power provided by WSC will be sufficient as an operational bound. Previous work indicated that the DAMA carrier power and the MA carrier power can be relatively the same [3]. For the algorithm developed however we must have enough power so that the DAMA carrier exhibits a peak against the MA spectrum. Based
on collected data for the $C_b/N_0 = 40$ case, the DAMA carrier is lost in the MA spectrum and in general cannot meet reliability requirements.

4.5 Conclusions of WSC Data Collection

We have shown some important results with the WSC Data Collection analysis. The algorithm using actual TDRSS signals performs nearly the same as when using synthesized signals (see Figure 4.4). Therefore the synthesis of modeled signals is accurate to actual TDRSS signals. We rely heavily on the simulation to provide proof of concept and so the justification of the simulation is vital: the simulation is used to narrow in on the operating parameters that we should like to run at. Though we only have significant data for the $PG = 10$ case, we extend the results described above to higher PG's with the assumption that the effects of spreading the signal even further in the frequency domain will cause negligible disparities between the simulation and actual operation. We can use simulated waveforms to implement additional, and important, real-time hardware tests.

There remains one outstanding issue with regards to accurate carrier estimation. We have seen previously that the TDRSS channel begins to rolloff sharply near the location that we would like to place the DAMA carrier. Though the data did not support the investigation—at least in the spectral matched filter case—it is nevertheless true that if the DAMA carrier is nominally placed too close to the
null, then the rolloff will adversely affect accuracy. We must also avoid placing the DAMA carrier in the MA passband.

Overall the successful comparison of captured data to simulation data indicates that provided the DAMA carrier has sufficient power, we can explore additional operation bounds with a high degree of confidence.
5 Carrier Estimation Hardware and Software

5.1 Motorola DSP56303EVM Description

The DSP56303EVM (EVM) is the core hardware component of the carrier estimation hardware developed. It executes the DSP specific real-time assembly language version of the carrier estimation algorithm (see Appendix B). The EVM is an evaluation module which is designed to be used in prototyping applications. As such, it offers a variety of interface options and configuration settings that make it adaptable to many different types of development projects. The board contains a DSP56303 24-bit digital signal processor that executes the assembly code routines. It also features a DSP56002 specifically for use in I/O functions through a JTAG/OnCE port. JTAG is a protocol that was developed to allow hardware and software developers to observe and manipulate hardware for troubleshooting purposes. The JTAG port for the EVM is primarily used with a PC and debugger software that allows a developer to load code into the EVM, single step through sections of code, and observe the contents of memory and registers. The onboard DSP56002 is not available for coprocessing code, but rather is used to control the I/O functions to the host PC. The EVM also contains 32K x 24-bit Fast Static Ram (SRAM) built with three banks of 32k x 8 bit SRAMS with 15 ns access times. An additional 64k x 8 bit Flash Programmable Erasable Read-Only Memory (PEROM) is provided for stand alone operation. The EVM also contains
a 16 bit CODEC for sampling incoming analog waveforms and producing analog waveforms out from digital data [11].

The EVM is based upon the DSP56300 core which is shown in Figure 5.1. The EVM specifically uses the DSP56303 processor. The processor is capable of 80 MIPS with an 80 MHz clock. It provides for backwards compatibility with 56k core code so that code written for earlier processors should function equally well on the newer cores. Due to a seven level instruction pipeline architecture, the DSP56303 is capable of effectively an instruction every clock cycle. It is based on the Harvard architecture so that it works with a dual memory structure. This architecture is particularly suited for parallel move instructions. This allows the
programmer to access two different memory structures at a time. For more on the DSP56303 please see [12].

The DSP56303 not only provides the processing power required to perform carrier estimation efficiently, but it is highly configurable and can interface to a large number of peripheral products. Though higher level languages (C) may be used to program the processor, it is most efficient when programmed in assembly. The assembly language that the DSP56303 uses is specialized to perform DSP tasks and includes features for that purpose. The Real-Time version of the carrier estimation algorithm is developed completely in assembly (see Appendix B).

To create a program for the DSP56303, code is written in assembly language, and then assembled through the use of Motorola software tools to machine usable object code (.cld files). We may then use a software tool like Domain Technologies Debug-EVM to load the code into program memory of the DSP56303. With the Debugger software, we can utilize the JTAG port to single step through code and observe the results on calculations.

For the DAMA project, as was described in section two, we are required to sample at a higher rate than the EVM can perform with the on board CODEC. We will use the on board CODEC in the generation of the locking tone to the ground station receiver. To sample the DAMA spectrum, we need to interface a high speed A/D.
5.2 Burr Brown 800kHz A/D

Earlier we noted we must search over a 300 kHz BW (200 kHz for the DAMA mainlobe, assuming no more than a \( PG = 100 \), and with \( \pm 50 \) kHz for maximum Doppler shift) which was revised from an earlier estimate of 364 kHz. The Burr Brown 12 bit 800 kHz ADS7810/19 (BB A/D) was chosen since it has a sampling frequency of 800 kHz which gives a Nyquist interval of 400 kHz and because it is available in a convenient evaluation package for easy interfacing to the DSP56303EVM. The 12-bit samples of the BB A/D have a dynamic range of -72 dB which is sufficient for the TDRSS system. It was necessary to build an interface board to allow samples collected with the BB A/D to be passed to the 303.

5.3 A/D Interface Board

The A/D Interface Board (ADIB) was developed as a Masters project by Tim Baggett [13]. Its purpose is to provide an interface to allow the EVM to communicate with the BB A/D. The board was developed to allow samples taken with the BB A/D to be passed into a peripheral (upper) memory location, which corresponds to the memory mapped I/O portion of memory. Though it is not a requirement, we may access the data samples with an efficient fast interrupt routine which is preferable. It is also possible with the interface board to use direct memory transfers (DMA) though this was not implemented in the Real-Time ver-
sion of the carrier estimation algorithm. The board allows for user configuration of the specific memory location the samples will be written in to. The ADIB was further complicated by voltage level discrepancies between the BB A/D and the 303. This was overcome through the use of zero wait-state level translators that adjust the output levels of the BB A/D to levels acceptable by the 303.

5.4 Additional Hardware

In an actual implementation of the DAMA carrier estimation hardware, there will be additional hardware required. Recall from the discussion of the DAMA project implementation, it was stated that WSC could provide the DAMA carrier at an IF of 32.65 MHz. The range of frequency values that a DAMA carrier can take, identified as 300 kHz, must be pre-filtered to bandlimit the signal containing the DAMA carrier from the MA waveform or aliasing will result. This is to be accomplished using an analog pre-filter set to a passband over the range of interest.

With the signal now appropriately pre-filtered, the signal must be frequency shifted to baseband utilizing additional commonly available analog hardware. With this pre-processing accomplished, the DAMA carrier can be sampled and the digital signal processed to detect and estimate the carrier frequency utilizing the algorithm described in section two. Upon the algorithm's determination of the DAMA carrier frequency, the CODEC on the EVM is utilized to provide a locking tone. By choosing a sample rate of 32 kHz for the synthesis of the locking tone, we
need only frequency multiply by 25 to get the appropriate frequency value (< 400 kHz). Afterward we frequency shift this tone back to IF for the GSR. This is illustrated in Figure 5.2. The analog hardware required to implement the frequency multiplication and shifting is commonly available and an essential component in implementation.

5.5 Software Description for Real-Time Carrier Estimation

The carrier estimation code is designed to work with the EVM and the ADIB to sample the incoming signal, process the signal, and then produce a locking tone to the ground station. The core of the program is based upon the code supplied with the EVM named pass.asm. The purpose of the pass.asm is to initialize the EVM (CODEC and processor), then transfer samples to/from the CODEC from/to the processor. All signal processing is performed between transfers. This code is important because in most cases of programming a Motorola DSP56xEVJ, the algorithm to be implemented will use pass.asm as the starting point. The carrier estimation code is slightly modified in that while it uses pass.asm as the core, it must set the EVM to properly receive samples from the BB A/D
and instead of reading sample values from the on-board CODEC, it will instead read sample values from an upper memory location as described above. Upon completing the initialization of the EVM (CODEC and processor) to work with the BB A/D, the carrier estimation algorithm begins. We begin by looking at the flowchart in Figure 2.6 which describes the algorithm.

The initial step from the reset condition is to initialize memory and on-board CODEC and prepare the EVM for communication with the ADIB. The algorithm then begins by filling the sample buffer with values. Once it has achieved a full block of 512 samples, it applies a windowing function of the user's choice. Typically either Rectangular or Hamming window coefficients are used. Included in this window function is an iteration scaling factor of $1/P$, where $P$ is the block number, which is nominally set to 0.125. This is included to scale for averaging. This has the added advantage of saving computation time since both windowing and average scaling are accomplished at once.

From the flowchart we now see that the actual FFT is performed. The FFT routine is supplied by Motorola (see Appendix B) and produces a normally ordered Fourier transform, as opposed to a bit-reversed, complex result from a normally ordered input. The result is stored such that the real component of the result is in $X$ memory and the imaginary in $Y$ memory. We compute the magnitude-squared of the FFT and repeat this step averaging magnitude-squared data $P = 8$ times to form the periodogram. If we assume that $x(n) \in \mathbb{R}$ where $x(n)$
is the received, sampled signal, we need only search the first $N/2$ points due to Hermitian symmetry

\[ X(k) = X^*(N - k), \quad 0 \leq k \leq N - 1. \quad (5.1) \]

This reduces the computational time and memory usage.

Continuing with the flowchart in Figure 2.6, once the periodogram is computed, we convolve the result with the SMF and begin a search for the maxima of the enhanced spectrum. The result of this search is an index corresponding to the dominant spectral component. From this index a frequency may be found according to the relation

\[ \hat{f} = \frac{k - \frac{L}{2}}{N} f_s, \quad (5.2) \]

where $\hat{f}$ is the estimated frequency [14], $k$ is the index found from the search, $L = N$ is the length of the SMF, $N$ is the number of points of the FFT, and $f_s$ is the sampling frequency. A sine wave table is then used to provide a locking tone at $1/25$ frequency that the ground station expects. As described above, this locking tone will be frequency multiplied up IF. The DSP56303 assembly code is given in Appendix B.
6 Conclusions and Future Work

In this thesis we have described an algorithm to perform carrier estimation for the DAMA project. We have shown that the estimation accuracy depends primarily on the processing gain of the SS BPSK signal though some tertiary parameters also affect accuracy. We have developed a simulation model that provides proof of concept and provides DAMA operational parameters. Through the use of data collected at the WSC, we have verified the simulation model and established an operational point of \( PG = 40 \) with a corresponding accuracy of 90%.

In addition to the development above, we have developed Real-Time code based on the algorithm developed utilizing a Motorola DSP56303EVM. The entire project is implemented in hardware and functions equivalently to the simulation model.

Future work might involve the formulation of a tighter theoretical bound as well the development of the analog hardware required for implementation. This work could be applied in other applications relating to communications between user spacecraft and commercial telecommunication satellites. In this scheme, additional carrier pre-shifting would be required.
A Matlab Simulation Code

009 % 4: Rb = 1000 bits/sec Rc = 40000 chips/sec
010 %
011 % Revision History:
012 %
013 % Ver 1.0: Baseline, one file generated per user input
014 % Ver 2.0: Four "useful" files generated at once, no user
015 % input. Some code cleaned up (vectorized).
016 % Ver 3.0: More vectorization, utilizes MATLAB's filter
017 % function. Vectors are pre-allocated.
018 % Ver 3.01: Changed code so that # of bits may be individually
019 % selected.
020 % Ver 4.0: To allow for larger data file generation, a menu
021 % system is implemented so that only one data file
022 % is generated. This compensates for memory
023 % problems. Edit file for different spread/data
024 % rates.
025 % Ver 4.01: "2047" NASA PN sequence took to long to generate
026 % so the sequence is generated offline for faster
027 % performance. This restricts resulting binary file
028 % length to 2meg.

001 % Title:
002 % cap.mf.m
003 %
004 % Purpose:
005 % The purpose of this code is to generate estimation data similar to
dama_mt with the exception that this code is tailored to use data
captured during the White Sands Complex (WSC) experiment.
008 %
009 % Revision:
010 % 1.0 -- 11/20/98
011 %
012 % Revision History:
013 % none => baseline
014 %
015 % Author:
016 % Brad Scaife
017 %
018 % Notes:
019 % This code requires as input data that has been prepared by vsco_d2.m which
020 % prepares the captured data and generates a matrix of usable vectors (see
021 % vsco_d2 comments for more information). This code also relies on an index
022 % matrix that is generated by in_prp.m. In both cases these files have already been
023 % prepared and may simply be loaded following prescribed naming conventions. In
024 % the event that these data files have been lost though it was thought helpful to
025 % comment on how to regenerate them.
026 %
027 % Average runtime:
028 % 8 minutes
029 %

end;
This code is to be used as driver code for wsco.m. This code converts captured whitesands files and converts them into usable length N blocks. Not entirely automated. Please read info in wsco.m for details on project purpose.

Input: This code requires the DAMA test files named as s1, s2, ..., sn.

Output: Undecided at this point.

Revision History:
- ver 1.0: baseline
- ver 2.0: Changed scope of code. This program is now to be used to drive other code only.
- ver 2.5: Restructured the format data is to be saved in.

Current Version - Date: 2.5 - 8/4/98

Author: Brad Scaife
Date: 7/23/98

Notes: Remember to change the save filename at the end of the code. Sorry got to do a little work to run this one.

Experiment One: Finding Probabilities and MSE estimates of estimating a complex sinusoid in noise. Purpose: The purpose of this code is to determine and prove the relationship between the DAMA curves and actual MSE of this estimation. This baseline test will provide insight into the simpler case of a complex sinusoid in noise which will then be extended to the more complex DAMA carrier case.

Notes: See Porat. As per indicated in Porat, the results of estimation are valid only when the "rule of thumb" are satisfied. Thus any processing of snr's below the ROT are not valid with the theoretical curve.

Program Parameters:

N = 512; % - Normally set to 512.
L = 8*N; % - Computational Resolution.

Nbase = N; % - Basic DFT resolution.
fs = 800e3; % - Sampling frequency.
Ts = 1/fs; % - Sampling interval.

f = 200e3 + fs/(8*N); % - Sinusoid frequency.
stim = 0; stime = (N-1)/fs;

phi = 0; % - Phase offset.
A = 1; % - Amplitude of sinusoid.

w = 1; % - Set as window function - see Porat.
D = Nbase*Ts; % - As per Porat.

snr = [-20:.5:30]';

number_estimates = 1000;

Calculated Program Parameters:

est_range = floor(fs/L)/2; % - Frequency estimation range as a function of basic DFT resolution.

f_lo = f - est_range; % - Lower "accurate" estimation bound.
f_hi = f + est_range; % - Upper "accurate" estimation bound.

k_lo = ceil(f_lo*N/fs); % - Lower index bound.

k_hi = floor(f_hi*N/fs); % - Upper index bound.
if $N \equiv N_{\text{base}}$

Experiment Two: Finding Probabilities and MSE estimates of estimating a real sinusoid in real noise.

Purpose: The purpose of this code is to determine and prove the relationship between the DAMA curves and actual MSE of estimation. This baseline test will provide insight into the simpler case of a complex sinusoid in noise which will then be extended to the more complex DAMA carrier case.

Programmer: Brad Scails
Date: 3/18/99
Revision Date: 3/18/99
Current Revision: 1.0
Revision History: 1.0 - Baseline
Notes: See Porat. As per indicated in Porat, the results of estimation are valid only when the "rule of thumb" are satisfied. Thus any processing of snr's below the ROT are not valid with the theoretical curve.

Program Parameters:
N = 65536; % - Normally set to 512.
Nbase = 65536; % - Basic DFT resolution.
fs = 800e3; % - Sampling frequency.
Ts = 1/fs; % - Sampling interval.
f = 200e3 + fs/(4*N); % - Sinusoid frequency.
stime = 0; etime = (N-1)/fs;
phi = 0; % - Phase offset.
A = 1; % - Amplitude of sinusoid.
Jv = 1; % - Set as window function - see Porat.
D = Nbase*Ts; % - As per Porat.

snr = [-20:.2:10]';
number_estimates = 100;

% Calculated Program Parameters
est_range = floor(fs/Nbase)/2; % - Frequency estimation range as a function of basic DFT resolution.
F_lo = f - est_range; % - Lower "accurate" estimation bound.
F_hi = f + est_range; % - Upper "accurate" estimation bound.
k_lo = ceil(f_lo*N/fs); % - Lower index bound.
k_hi = floor(f_hi*N/fs); % - Upper index bound.

if N == Nbase

Core Interrupt Priority Configuration Routine:

Purpose: The purpose of this routine is to set the core Interrupt priorities. For the DAMA Project, only IRQB need concern us presently. Thus, only bits 6 to 3 are relevant. The following table suggests the proper settings:

<table>
<thead>
<tr>
<th>IBL2</th>
<th>IBL1-0</th>
<th>Enabled</th>
<th>No</th>
<th>Yes</th>
<th>Yes</th>
<th>Yes</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>00</td>
<td>00</td>
<td>1</td>
<td>2</td>
<td>2</td>
<td>2</td>
</tr>
</tbody>
</table>

For details see 303UM:D-17.

Current Settings:
Currently IRQB is the only interrupt enabled and it has been set to priority level 2 (highest) and negative edge triggering.

Sine-Cosine Table Generator for FFTs.

Last Update 25 Nov 86 Version 1.2

sincos macro points,coef
sincos ident 1,2

sincos - macro to generate sine and cosine coefficient lookup tables for Decimation in Time FFT

points - number of points (2 - 32768, power of 2)
coef - base address of sine/cosine table

negative cosine value in X memory
negative sine value in Y memory

Latest revision - 25-Nov-86

pi equ 3.141592654
freq equ 2.0*pi/6cvf(points)

org x:coef

ADA_INIT.ASM

Ver.2.0

Example program to initialize the CS4215

Copyright (C) MOTOROLA 1995, 1996

Semiconductor Products Sector

Digital Signal Processing Division

History:

14 June 1996: RLR/LJD - ver.1.0

PLEASE NOTE: For use with rev 2.1 code.

port usage:

bit8: SSI TX (from DSP to Codec)

bit7:

bit6:

bit5:

bit4: codec reset (from DSP to Codec)

bit3:

bit2: data/control bar

0=control

1=data

initialize the CS4215 codec

-program outline:

1 program fsync and sclk == output

2 write pc0 = 0 (control mode)

3 send 64 bit frame x times, with dbi bit = 0, keep doing until read back as 0

4 send 64 bit frame x times, with dbi bit = 1, keep doing until read back as 1

5 re-program fsync and sclk == input

6 write pc0 = 1 (data mode)

7 receive/send data (echo slots 1,2,3,4; slots 5,6,7,8 == constants)

initialize ssi -- fsync and sclk ==> outputs

org p:

ada_init

movp #$0000,x:M_PCR

movp #$0103807,x:M_CRAO

movp #$ff313C,x:M_CRBO

movp #$0003,x:M_PRR

movp #$0,x:M_FDR

--------reset delay for codec------

do #10000,delay_loop

rep #2000

100 us delay (assuming 40MHz VCD)

nop

_delay_loop

130
bset #0,x:M_PDRC ; sends out a 1 on pD0 (rst_codec=1)
movep #0008,x:M_IPRP ; set interrupt priority level for ESSIO to 1
andi #$FC,mr ; enable interrupts

The following data sets up the CS4215 control mode data:

(CTS = Control Time Slot, U/LN = upper/lowerNibble)

+-----
CTS1-UN: 0 0 1 MLB 0 0 0 0
|+-----
CTS1-LN: CLB CLB X X 0 0 0 0
+-----
CTS2-UN: HPF X DFR2 DFR1 0 0 1 0
|+-----
CTS2-LN: DFRO ST DF1 DFO 1 1 0 0
x0 = $002Cxx

+-----
CTS3-UN: ITS MCK2 MCK1 MCK0 1 0 0 0
|+-----
CTS3-LN: BSEL1 BSEL0 XCLK XEN 1 0 0 0

x0 = $8800xx

set up buffer with control mode data

move #CTRL_WD_12,x0
move x0,x:TX_BUFF_BASE
move #CTRL_WD_34,x0
move x0,x:TX_BUFF_BASE+1
move #CTRL_WD_56,x0
move x0,x:TX_BUFF_BASE+2
move #CTRL_WD_78,x0
move x0,x:TX_BUFF_BASE+3
movep #003C,x:M_PCRC ; turn on ESSIO except for sc0 and sc2

CLB == 0

jclr #3,x:M_SSISRO,* ; wait until rx frame bit==1
jset #3,x:M_SSISRO,* ; wait until rx frame bit==0
jclr #3,x:M_SSISRO,* ; wait until rx frame bit==1
jset #18,x:RX_BUFF_BASE,* ; loop until CLB set

movep #003C,x:M_PCRC

CLB == 1

be set #18,x:TL_BUFF_BASE ; set CLB

do #_init_loopB

jclr #2,x:M_SSISRO,* ; wait until tx frame bit==1
jset #2,x:M_SSISRO,* ; wait until tx frame bit==0

_movep #0000,x:M_PCRC ; disable ESSIO

now CLB should be 1 -- re-program fsync and sclk direction (i/p) -- also,
circular buffer pointers for echoing data r0=current, r1=old data to send 1 frame later

movep #103807,x:M_CRAO ; 40MHz/16 = 2.5MHz SCLK, WL=16 bits, 4W/F
movep #FFS10C,x:M_CAB0 ; sckd and fsync (sc02) as inputs
movep #0003,x:M_PDRC
movep #000C,x:M_PCRC ; turn on ESSIO except for sc0 and sc2
