Abstract

We present a disturbance rejection mechanism for the formation flying of multiple spacecraft based on a robust control approach in terms of an $H_{\infty}$ control problem. The corresponding $H_{\infty}$ control problem is then solved numerically using linear matrix inequalities.

1 Introduction

Formation flying (FF) has been identified as an enabling technology for many of the NASA's 21st century missions, among them, the Deep Space 3 and the Terrestrial Planet Finder. Formation flying involves flying a group of spacecraft in a particular pattern while maintaining precise (but often time varying) relative position, velocity, attitude, and angular velocity, with respect to each other [2], [6]. Since traditional spacecraft control is often concerned with measuring and maintaining the same quantities for a single spacecraft with respect to an inertial reference frame, the analogous FF control and estimation problems are often an order of magnitude more challenging than those encountered traditionally for a single spacecraft. In order to make the FF control problems at least similar to the single spacecraft case, an approach based on leader-following has been proposed by Wang and Hadaegh [7] (also refer to [8]). The basic idea in leader-following (LF) is to designate a particular frame (or multiple frames) in the FF as the reference frame(s) and measure and control the states of the rest of the formation with respect to them.

The present paper addresses the problem of designing a control law for the follower spacecraft in an LF formation which is guaranteed to attenuate the effects of environmental disturbances on the performance of the leader following. The results of the paper are in direct relevance to those reported [4] and [7] for the formation keeping problem. Building on the basic feedback linearization scheme in [7], we propose a control mechanism for the formation in the presence of disturbance forces and torques based on the $H_{\infty}$ methodology. The linear matrix inequality (LMI) [1] formulation of the corresponding $H_{\infty}$ problem is then used to design a candidate controller which is, in the $H_{\infty}$ sense, optimal.

The organization of the paper is as follows. In §2 the assumptions which constitute the framework for the formation keeping problem are listed. In §3 and §4 the basic facts and the formulation of the problem considered in the paper are presented, followed by the design techniques which introduce the $H_{\infty}$ formulation of the disturbance rejection. A numerical example and the corresponding simulation result are then presented in §5.

First a few words on the notation. Formation flying consists of flying a group of spacecraft in a particular pattern. To be able to express the time evolution of the formation and design the corresponding control laws, it is convenient that a reference frame is attached to each spacecraft. We shall always assume that these reference frames are induced from a dextral set of three orthonormal vectors. Let the formation have $n$ spacecraft labeled as $1, 2, \ldots, n$. Let $\mathcal{F}^i$ denote the reference frame attached to the $i$-th spacecraft; $\mathcal{F}^1$ on the other hand shall designate the inertial reference frame. For the inertia and the mass of the $i$-th spacecraft we use $m^i$ and $m^1$, respectively. The force and torque acting upon $i$ are denoted by $\mathbf{f}^i$ and $\mathbf{r}^i$; for the mass normalized force we used $\mathbf{u}^i := \frac{\mathbf{f}^i}{m^i}$. The time derivative with respect to $\mathcal{F}^1$ shall be denoted by $\frac{d}{d\mathcal{T}^1}$; likewise, $\frac{d}{d\mathcal{F}^1}$ will be used for the time derivative with respect to $\mathcal{F}^1$. $\mathbf{r}^0$ denotes the position of the origin of $\mathcal{F}^1$ with respect to $\mathcal{F}^1$; $\mathbf{r}^1$ is the position of the origin of $\mathcal{F}^1$ with respect to $\mathcal{F}^1$. The desired position of the origin of $\mathcal{F}^1$
with respect to $\mathcal{F}^I$ shall be denoted by $r^I_J$, and by $r^I_j$ when $j = I$. The velocity of the origin of $\mathcal{F}^I$ with respect to $\mathcal{F}^J$, the velocity of the origin of $\mathcal{F}^I$ with respect to $\mathcal{F}^I$, the desired velocity of the origin of $\mathcal{F}^I$ with respect to $\mathcal{F}^J$, and the desired velocity of the origin of $\mathcal{F}^I$ with respect to $\mathcal{F}^I$, shall be denoted by $v^I_J$, $v^I_I$, $v^I_J$ and $v^I_I$, respectively. Similar notation is used for the angular velocity of $\mathcal{F}^I$ with respect to $\mathcal{F}^J$. Under these assumptions, the follower chooses its control force and torque based on the knowledge of its own dynamics and the control that was used by the leader to track a desired trajectory. We note that relaxing some of these assumptions result in a significant change in the techniques which can be used to address the formation keeping problem.

3 First, Feedback Linearization

Under the stated assumptions in §2, we consider the scenario where the leader's position, with respect to $\mathcal{F}^I$, evolves according to,

$$\frac{dr^I}{dt} = v^I, \quad \frac{dv^I}{dt} = \frac{F^I}{m} = u^I.$$

The control force $F^I$ is chosen independent of the followers according to some mission objectives, optimality criteria, etc.

Recall that the first and second derivatives of a vector $A$ in $\mathcal{F}^I$ and $\mathcal{F}^I$ are related by the following relation,

$$\frac{dA}{dt} = \frac{dA}{dt_I} + \omega^I \times A,$$

(3.1)

where $\omega^I$ is the angular velocity of $\mathcal{F}^I$ with respect to $\mathcal{F}^I$.

In particular,

$$\frac{d\omega^I}{dt} = \frac{d\omega^I}{dt_I} + \omega^I \times \omega^I = \frac{d\omega^I}{dt_I},$$

stating that the rate of change of the angular velocity is independent of the frame of reference.

Differentiating both sides of (3.1) with respect to $\mathcal{F}^I$ we obtain,

$$\frac{d^2A}{dt^2} = \frac{d^2A}{dt^2_I} + \omega^I \times A + 2\omega^I \times \frac{dA}{dt_I} + \omega^I \times (\omega^I \times A).$$

(3.2)

Let,

$$r^I_J(t) = r^I(t) + h^I(t), \quad t_0 \leq t \leq t_f.$$
the error is thus,
\[ e^i(t) = r^i(t) - r^i(t) \]
\[ = r^{1i}(t) + h^i(t), \]
(3.3)
where \( r^{1i} \) is the vector from (the origin of) \( F^i \) to (the origin of) \( F^1 \), i.e., the position of the leader with respect to the \( i \)-th follower spacecraft coordinates. We like to obtain an expression which describes the time evolution of \( e^i \) in \( F^1 \).

From (3.3) one has,
\[ \frac{d^2 e^i(t)}{dt^2} = \frac{d^2(r^{1i}(t))}{dt^2} + \frac{d^2 h^i(t)}{dt^2}; \]

however,
\[ \frac{d^2(r^{1i}(t))}{dt^2} = \frac{d^2(r^i(t) - r^i(t))}{dt^2} = u^i(t) - u^i(t). \]
(3.4)

In view of (3.2) we have,
\[ \frac{d^2 e^i(t)}{dt^2} + \frac{d \omega^i(t)}{dt} \times e^i(t) + 2 \omega^i(t) \times \frac{de^i(t)}{dt} + u^i(t) \times (\omega^i(t) \times e^i(t)) \]
\[ = (u^i(t) - u^i(t)) + \frac{d^2 h^i(t)}{dt^2}, \]
(3.5)
where \( u^i \) represents the total normalized force acting on the \( i \)-th spacecraft, i.e.,
\[ u^i(t) = u^i_1(t) + u^i_2(t). \]

The last term on the right hand side of (3.6) can of course be represented in \( F^1 \) as,
\[ \frac{d^2 h^i(t)}{dt^2} + \frac{d u^i(t)}{dt} \times h^i(t) + 2 \omega^i(t) \times \frac{dh^i(t)}{dt} + u^i(t) \times (\omega^i(t) \times h^i(t)). \]
(3.7)

The rate of change of the angular velocity \( \omega^i \) with respect to \( F^1 \) or \( F^1 \) is related to the torque applied on the spacecraft via the Euler's equation,
\[ \frac{d \omega^i(t)}{dt} = (I^i)^{-1}(r^i(t) - \omega^i(t) \times (I^i \omega^i(t))). \]
(3.8)

Again the term \( r^i \) represents the total torque on the \( i \)-th spacecraft, i.e.,
\[ r^i(t) = r^i_1(t) + r^i_2(t). \]

Now, (3.6) represents how the error vector \( e^i \) evolves in \( F^1 \). We would like to obtain an expression for \( u^i \), such that the origin of the globally asymptotically stable limit point of the trajectories defined by (3.6) in the presence of environmental disturbances \( u^i_2 \) and \( r^i_2 \). For this purpose we let,
\[ x_1(t) = e^i(t), \]
\[ x_2(t) = \frac{de^i(t)}{dt} := \dot{x}_1(t), \]
\[ x_3(t) = \omega^i(t). \]

The dynamics of the \( i \)-th spacecraft can thus be expressed as,
\[ \dot{x}_1(t) = x_2(t), \]
\[ \dot{x}_2(t) = -2 x_3(t) \times x_2(t) - (I^i)^{-1}(r^i_1(t) + r^i_2(t)) \]
\[ - x_3(t) \times I^i_1 x_3(t) \times x_1(t) - x_3(t) \times x_3(t) \times x_1(t) \]
\[ + (u^i(t) - u^i_2(t) - u^i_2(t)) + \frac{d^2 h^i(t)}{dt^2}, \]
(3.10)
\[ \dot{x}_3(t) = (I^i)^{-1}(r^i_2(t) + r^i_2(t) - x_3(t) \times I^i x_3(t)). \]
(3.11)

The differential equations (3.9)-(3.11) describe a nonlinear dynamical system whose state represents the evolution of the position error, position rate error, and the angular velocity of the follower spacecraft, in the follower's coordinate system. In general, one would like to choose the control action such that the error terms go to zero, while certain optimality conditions, and state and control constraints are satisfied. Since designing non-conservative optimal nonlinear controllers in their full generality is a formidable task, one often restores to less ambitious objectives, via for example feedback linearization.

We notice that the parameters available for the control purposes are control force \( u^i_1 \) and torque \( r^i_1 \). However, the control torque might be independently used to obtain a desired orientation during the maneuver, in which case, one would merely focus on obtaining an expression for \( u^i_1 \).

Suppose that the control force and torque are represented as,
\[ u^i_1(t) = \hat{u}_1^i(t) - u^i_2(t), \]
\[ r^i_1(t) = \hat{r}_1^i(t) + r^i_2(t), \]
where,
\[ \hat{u}_1^i(t) := 2 x_3(t) \times x_2(t) + x_3(t) \times (x_3(t) \times x_1(t)) \]
\[ - u^i(t) - \frac{d^2 h^i(t)}{dt^2} - (I^i)^{-1}\hat{z}_1^i(t) \times x_1(t), \]
\[ \hat{r}_1^i(t) = x_3(t) \times I^i_1 x_3(t). \]

The subscript '\( f \)' above is used to denote the 'feedback linearization' term. The dynamics is thus simplified to,
\[ \dot{x}_1(t) = x_2(t), \]
\[ \dot{x}_2(t) = -u^i_1(t) - u^i_2(t) - (I^i)^{-1}r^i_2(t) \times x_1(t), \]
\[ \dot{x}_3(t) = (I^i)^{-1}(\hat{r}_1^i(t) + r^i_2(t)). \]

Let \( T = -(I^i)^{-1}r^i_2 \). From the statistics of \( r^i_2 \), we construct the set
\[ \Omega \subseteq \mathbb{R}^{3 \times 3} \text{ such that } T \in \Omega \]
with a probability which can be chosen to be arbitrary close to one; now consider the convex hull of \( \Omega \). For the purpose of the present discussion we shall assume that the convex hull is a polytope in \( \mathbb{R}^{3 \times 3} \). Thus, there exists matrices \( T_1, \ldots, T_t \), such that
\[ T \in \text{Co} \{ T_1, \ldots, T_t \} , \]
where $C_0$ denotes the operation of taking the convex hull of a set.

The dynamics of the leader following can thus be represented as,

$$
\begin{bmatrix}
\dot{x}_1(t) \\
\dot{x}_2(t) \\
\dot{x}_3(t)
\end{bmatrix}
= 
\begin{bmatrix}
0 & I & 0 \\
0 & T & 0 \\
0 & 0 & 0
\end{bmatrix}
\begin{bmatrix}
x_1(t) \\
x_2(t) \\
x_3(t)
\end{bmatrix}
+ 
\begin{bmatrix}
0 & 0 & 0 \\
-I & -(I^t)^{-1} & 0 \\
0 & -(I^t)^{-1} & 0
\end{bmatrix}
\begin{bmatrix}
u_1(t) \\
\tau_1^d(t) \\
\tau_2^d(t)
\end{bmatrix}
$$

and let,

$$
u(t) := \begin{bmatrix} \hat{u}_1^d(t) \\ \tau_1^d(t) \end{bmatrix}, \quad w(t) := \begin{bmatrix} u_1^d(t) \\ \tau_2^d(t) \end{bmatrix}.
$$

The dynamical equations which describe the evolution of the follower spacecraft can therefore be summarized as the following linear differential inclusion [1], [3],

$$
\dot{z}(t) = Az(t) + Bu u + B_w w(t),
$$

where,

$$
A \in \text{Co} \{A_1, \ldots, A_l\}.
$$

The output equation can generically be represented as,

$$
z(t) = C_z x(t) + D_2 u(t) + D_{1w} w(t).
$$

In the subsequent section, we shall build on the linearization and the embedding procedure described above to propose a state feedback linear controller for the formation keeping problem which attenuates the effects of the disturbance vector $\begin{bmatrix} u_1^d(t) \\ \tau_2^d(t) \end{bmatrix}$ on the state of the follower spacecraft.

4 RMS Gain and State Feedback Synthesis

We model the disturbance vector $w(t) := \begin{bmatrix} u_1^d(t) \\ \tau_2^d(t) \end{bmatrix}$, as a stationary stochastic process having a finite RMS norm, defined to be,

$$
\|w(t)\|_{\text{RMS}} := \left( \lim_{T \to \infty} \frac{1}{T} \int_0^T w(t)'w(t) \, dt \right)^{1/2}.
$$

It is known that for an ergodic wide-sense stationary stochastic signal, the RMS norm can be expressed in terms of the power spectral density function $S(\omega)$,

$$
\|w(t)\|_{\text{RMS}} = \text{Trace} \left( \frac{1}{2\pi} \int_{-\infty}^{\infty} S_w(\omega) \, d\omega \right).
$$

Now consider the follower spacecraft dynamics after the feedback linearization, as represented by (3.13) (Figure 2). For each $T_i$ one as a linear time invariant system; let the corresponding transfer matrix be denoted by $G_i(s)$. The RMS gain of a transfer matrix $G_i$ or its $H_\infty$ norm is the largest ratio of the RMS norm of the noise signal $w$ to the RMS norm of the output signal $z$, i.e.,

$$
\|G_i(s)\|_{\infty} := \sup_{\|w(t)\|_{\text{RMS}} \neq 0} \frac{\|z(t)\|_{\text{RMS}}}{\|w(t)\|_{\text{RMS}}}.
$$

It can also be shown that,

$$
\|G_i(s)\|_{\infty} := \sup_{\omega} \sigma_{\text{max}}(G_i(j\omega)),
$$

where $\sigma_{\text{max}}(G_i(j\omega))$ denotes the maximum singular value of the (complex) matrix $G_i(j\omega)$ [1].

We now focus on proposing a state feedback control law which has as its goal, the minimization of the RMS gain of the resulting family of closed loop feedback systems which represent the follower spacecraft dynamics.

4.1 State Feedback Synthesis

In this section we present a state feedback control which aims to minimize the RMS gain of the family of closed loop systems which represent the dynamics of follower spacecraft. The follower dynamics with the controller in the feedback loop can thus be represented as in Figure 2, where $K$ is considered to be a constant state feedback gain.

For simplicity of the present discussion, we shall assume that $D_{1w} = 0$, i.e., that the noise does not directly affect the output signal $z$. Let $u(t) = Kz(t)$ in (3.14)-(3.15); thus,

$$
\dot{z}(t) = (A + B_2 K)z(t) + B_2 w(t).
$$

In order to minimized the RMS gain from $w$ to $z$, consider the Lyapunov function $V(x, t) = x(t)'Px(t)$, where

Figure 2: The open loop block diagram for the follower spacecraft (the plant $P$ represents one of the $G_i$’s).
the matrix $P$ is positive definite. Suppose that $P$ is chosen such that there exists a nonnegative number $\gamma$ satisfying (1)

$$\frac{d}{dt}V(x, t) + z(t)'z(t) - \gamma^2 w(t)'w(t) \leq 0. \quad (4.16)$$

Thereby,

$$\lim_{T \to \infty} \frac{1}{T} \int_0^T z(t)'z(t) \, dt - \lim_{T \to \infty} \frac{1}{T} \int_0^T \gamma^2 w(t)'w(t) \, dt \leq 0,$$

since $V(x(T)) \geq 0$. Thus one can deduce that,

$$\|z(t)\|_{\text{RMS}} \leq \gamma,$$

i.e., one can bound the RMS gain of the closed loop system by $\lambda$ by an appropriate selection $K$ which admits a quadratic Lyapunov function with the desired properties.

Expanding the condition (4.16) for the family of transfer matrices $G_i$'s ($i = 1, \ldots, l$), one obtains,

$$(Az(t) + B_u u(t) + B_w w(t))'Pz(t) + z(t)'P(Az(t) + B_u u(t) + B_w w(t))$$

$$+ (C_s z(t) + D_{su} u(t) + D_{sw} w(t))' (C_s z(t) + D_{su} u(t) + D_{sw} w(t)) - \gamma^2 w(t)'w(t) \leq 0, \quad (4.17)$$

for all $A \in \text{Co}\{A_1, \ldots, A_l\}$ and all $z \in \mathbb{R}^p$.

After some simplifications, and setting $Q := P^{-1}$, and $Y = KQ$ (4.17) can be written as,

$$\begin{bmatrix} X_{1i} & X_{2i} \\ X_{2i} & X_{3i} \end{bmatrix} \leq 0,$$

$$(i = 1, \ldots, l),$$

where,

$$X_{1i} = A_i Q + QA_i' + B_u Y + Y'B_u' + B_w B_w' ,$$

$$X_{2i} = (C_s Q + D_{su} Y)',$$

$$X_{3i} = -\gamma^2 I.$$

Thus, in order to find a controller which aims to minimize the RMS gain of the family of closed loop systems representing the follower spacecraft dynamics, we are led to solve the following semi-definite program,

$$\min_{Y, Q, \gamma} Q > 0, \quad \left[ \begin{array}{c} A_i Q + QA_i' + B_u Y + Y'B_u' + B_w B_w' \\
(C_s Q + D_{su} Y)' \\
\end{array} \right] (i = 1, \ldots, l),$$

and then let $K = YQ^{-1}$.

5 An Example

In this section we provide an example and the corresponding simulation result for the proposed state feedback synthesis procedure discussed above. For this purpose, given the matrices $A_1, \ldots, A_l, B_u, B_w$, as in (3.14), we chose the following matrices for the simulation purposes,

$$C_s = I \quad \text{and} \quad D_{su} = 0.$$

The LMItool, an optimization package developed by El Ghaoui, Nikoukhah, and Delebecque based on the SP code of Boyd and Vandenberghe, implementing the primal/dual interior point method for solving semi-definite programs, was used to solve the SDP (4.18)-(4.18). The disturbance force and torque was modeled as a band limited white noise. The simulation result is depicted in Figure 3.

6 Conclusion

We proposed a disturbance rejection mechanism for the formation keeping problem. The disturbance rejection problem is first formulated in terms of a family of $H_\infty$ optimization problems. We then proceeded to solve these
\[ H_{\infty} \] problem using their LMI formulations via the recently proposed interior point methods. A numerical example was provided to demonstrate the usefulness of the proposed approach for formation flying in the presence of RMS bounded disturbance forces and torques.
