NEW MILLENNIUM PROGRAM

Serving Earth and Space Sciences

Fuk Li

Jet Propulsion Laboratory
California Institute of Technology

March 18, 1999
Ambitious Plans

Office of Earth Science

- EOS Post 2002
- LandSat Follow-on
- NPOES
- Advanced Geostationary
- ESSP

Office of Space Sciences

- Mars Exploration
- Outer Planets
- Discovery
- Solar Terrestrial Probes
- UNEX/SMEX/MIDEX
- Gravity Probe B/LISA
- Next Generation Space Telescope
- Space interferometry Mission/Terrestrial Planet Finder
Advanced Technologies: Essential to Achieve OES and OSS Objectives

Science Missions

Impediments to Rapid Technology Infusion:
- Lack of flight heritage
  - real or perceived risks
    - cost
    - schedule
    - performance
- Little visibility to mission planners
  - capabilities poorly understood
  - A complete paradigm shift is needed to fully exploit some technologies
The New Millennium Program

A cross-Enterprise program to identify and flight validate breakthrough technologies that will significantly benefit future Space Science and Earth Science missions

- Breakthrough technologies
  - Enable new capabilities to meet Earth and Space Science needs
  - Reduce costs of future missions

- Flight validation
  - mitigates risks to first users
  - enables rapid technology infusion into future missions
Common Processes for Earth & Space Sciences Programs

- Identification of Needs
- Identification of Tech.
- Project Formulation
- Technology Selection
- Project Implementation & Tech Validation
- Technology Infusion

Needs & Opportunities
Flight Project Formulation Process
Deep Space One: Asteroid Flyby

- Validate Technologies for Rapid Access in Deep Space Exploration

Advanced Solar Concentrator Array
Able Engineering Inc., BMDO, Entech, JPL, Lewis Research Center, & Tecstar

Miniature Integrated Camera Spectrometer
Boston U. JPL, Rockwell SSG, Inc., USGS, & U of AZ

Autonomy Remote Agent Architecture
Ames Research Center Carnegie Mellon U & JPL

Plasma Experiment for Planetary Exploration
SwRI & Los Alamos National Lab

Autonomous Onboard Optical Navigation
JPL

NSTAR Ion Propulsion System
Hughes, JPL, Lewis Research Center, MSFC, Moog Inc., Physical Science & Spectrum Astro

Multifunctional Structures
Air Force Phillips Lab & Lockheed Martin

Spacecraft
Spectrum Astro, JPL

Small Deep Space Transponder
JPL & Motorola

Ka-Band Solid State Power Amplifier

</table>
| Ion Propulsion Engine                           | - save a factor of 2-3 in flight time while significantly increasing launch margin  
- provides a 7:1 solar concentration factor, offers significant array cost reduction due to the reduced (1/7) quantity of cells  
- most efficient (13%), highest power (2.6 W), space qualified  
- 3 times mass reduction and single unit architecture  
- provide faster response to in-flight situation (<1min vs. 3 days), reduce mission dev. cost and operations cost (>30%) | - station keeping  
- power generation  
- high band communication and freq. alternative  
- autonomous operations, event detection | - primary propulsion & station keeping  
- power generation  
- high performance com  
- small & low mass communication  
- autonomous operations, uncertainty handling |
| Solar Concentrator Array                        |                                                                                                                                                                                                              |                                                                                                            |                                                                                                           |
| Ka-band Solid State Power Amplifier             |                                                                                                                                                                                                              |                                                                                                            |                                                                                                           |
| Deep Space Transponder                          |                                                                                                                                                                                                              |                                                                                                            |                                                                                                           |
| Remote Agent Experiment                         |                                                                                                                                                                                                              |                                                                                                            |                                                                                                           |
| Beacon Monitor Operations                       | - achieves large reduction in ops. staffing; reduces the loading on an already over constrained DSN  
- greatly reduce tracking, save nav. staff by a factor of 2-3, & enhance mission science  
- SiC structure and optics will allow for alignment and focus of optics at ambient temp with no change for operation at cryogenic temps | - autonomous operation  
- small camera/spectrometer  
- deep space navigation  
- small camera/spectrometer  
- autonomous operation | - autonomous operation

Common Benefits of Processes

- Enhanced NASA's technology community through partnerships
  - Industry
  - Academia
  - Government Laboratories
- Infusions into future missions
  - Future projects using NMP validated technologies
  - Technology database for PI missions
    - New capabilities enable new opportunities
    - MIDEX/SMEX/Discovery/ESSP
Enhanced NASA's Technology Community through Partnerships (NMP Flight Team & Technology Partners)
Solar Electric Propulsion Future Users

- **Space Science**
- **Benefits of Solar Electric Propulsion**
  - Transportation
  - Formation Flying
  - Station Keeping/Orbit Maintenance

- **Earth Science**

**Electric Propulsion**
- NSTAR Ion Propulsion
- EOI Pulsed Plasma Thruster
- ESSP
Hyper/Multi-Spectral Imagers & Spectrometers Future Users

Earth Science
- Potential replacement for multi-spectral Landsat imaging
- Hyper-spectral imaging spectrometer provides new observational capabilities

- Planetary & solar plasma scientists have proposed to use copies of the PEPE instrument for future missions
- Validation of an all SiC optical instrument covering the FUV to SWIR will enable many new miniature, low-mass cameras and spectrometers

Space Science
- MICAS camera design will be proposed for Pluto Flyby mission
Thinking Spacecraft Future Users

Autonomous Optical Navigation

Enhanced Formation Flying

Autonomous Navigation & Control

Remote Agent

Autonomous Operations

Earth Science
- Formation flying and/or autonomous operations for EOS and ESSP Missions
- Magnetospheric Multiscale, Magnetospheric Constellation
- Self monitoring for Europa Orbiter, MIDEX proposals & Earth orbiters

Autonomous optical navigation for Stardust, and Europa Orbiter

Automatic sequencing & real time control for interferometer instruments such as TPF and LISA

Space Science
Micro-Nano Spacecraft's Future Users

- Multifunctional structure
- Carbon-carbon radiator
- Wideband Advanced Recorder/Processor
  - DS1
- Advanced Micro Controller
  - DS2
- Small Deep Space Transponder
  - DS1
- Low Power Electronics
- Power switching module

Innovations that simplify design, fabrication, reduces mass & reduce resource requirements

Earth Science

- Potential for EOS Follow-On
- ESSP

Space Science

- Mars Micro missions
- STP Magnetospheric Multiscale Mission
- Discovery
- UNEX/SMEX/MIDEX
High Data Rate Future Users

Space Science
Mars '01

- Reduces mass, volume & mechanical complexity for high data rate missions
- Essential for high-bandwidth spectral imaging instrument and active instruments (radars/lidars)

The Advanced Land Imager (ALI) is the centerpiece of the New Millennium, Earth Orbiter-1 mission's ALI will validate technologies contributing to the reduction in cost of future land imaging missions such as the Landsat series or earth imaging missions. The ALI will provide multi-spectral (10 bands), high spatial resolution (300m) in the visible and near infrared spectral range (0.5 to 2.5 um) with the goal of 5% absolute radiometric accuracy. The EO-1 mission will fly in formation with Landsat 7 and collect more than 200 common scenes for comparison.

The ALI will be a factor of 4 less in mass and 5 less in power than the Landsat 7 Enhanced Thematic Mapper (ETM+). The flight validation of key ALI technologies should lead to dramatically reduced cost and complex Landsat type missions. Some of the key technologies are:

1. Silicon Carbide Optics which are extremely lightweight optics that are stable over a wide range of temperatures. The goal is to demonstrate how well the Silicon Carbide maintains stable performance in a space environment.

2. Wide field, high resolution reflective optics which provides a full Landsat scene swath width (185km) and resolution using a simple push broom design. This technique will enable much lower cost instrumentation for future Landsat mission through use of non-mechanical scanning and reduced instrument complexity.

3. Multi-spectral imaging capability, the modular focal plane assembly provides substantial mass and power savings over comparable mechanical scanning instruments through innovative electro-optical design. Additionally, an innovative on-board calibration system will enable better characterization of instrument performance during observations.

Applicability
The ALI is a pathfinder to higher performance and lower cost land imaging instruments which meet the demanding Earth Science Enterprises requirements for remote sensing applications.

Benefit to Earth Science Missions
The ALI technologies reducing the mass, power, complexity and cost of future earth imaging systems for the Earth Science Program. A fully operational ALI has potential for reducing the cost and size of future Landsat type instruments by a factor of four to five.

Description of Technology:
NSTAR is a high-specific impulse solar electric propulsion system for deep space primary propulsion. The NSTAR system consists of five principal elements:
1. A 30-cm ion thruster capable of processing 83 kg at power levels between 500 W and 2,500 W and providing 93 mili-N of thrust and an I<sub>sp</sub> of 3,120 lb-sec/lb at maximum power.
2. A power processing unit (PPU) capable of providing the necessary voltages and currents required by the ion thruster from an input power source providing between 80 V and 160 V. Each power processing unit can control two ion thrusters sequentially, but not simultaneously.
3. A digital control interface unit (DCIU) that provides the command and telemetry interface with the spacecraft, which controls the power processing unit - establishing proper set points for each thruster level commanded by the spacecraft, and which controls the flow rates provided by the propellant storage and control system.
4. A propellant storage and control system (PSCS) that provides xenon to the ion engine at the flow rates commanded by the DCIU for each thruster level.
5. A diagnostics measurement system to measure induced fields during ion thruster operation to help verify the performance of the ion propulsion system and to measure the effect of its operation on the spacecraft plasma and plasma. The diagnostics system is not required for operational use of the ion propulsion system.

Applicability
The NSTAR engine is applicable to many deep space missions, and particularly valuable for missions to distant or high delta-v targets.

Benefit to Deep Space Missions
NSTAR provides significantly higher specific impulse than conventional chemical propulsion. This translates into a smaller mass of fuel required to accelerate a spacecraft to a given velocity. On missions to distant objects or trajectories requiring a large delta-v, where the fuel mass is a significant factor, a smaller fuel load at launch can mean a smaller, lower cost launch vehicle, or it can be traded for higher spacecraft velocity or a shorter cruise time to the target for a given launch vehicle capacity.

**Description of Technology**

The Advanced Microcontroller (AMC) is the world's smallest space-qualified self-contained computer. It was designed for high-impact, cold-temperature applications on the Martian surface (30,000 G's, -120 deg C). The AMC has modest amounts of computing power (about the equivalent of an old "Apple II" computer), but achieves this in the size of a postage stamp (0.8" x 1.2"), the mass of a few potato chips (3 grams), and 1/20" watt of electrical power. Unlike an "Apple II", the AMC packs an impressive built-in instrumentation capability: six serial communications ports, 32 digital discrete lines, an additional 32 analog input lines, and eight potentiometer analog outputs. The AMC runs off of its own internal clocks (either 10 MHz or 200 Hz for ultra-low-power) or an externally provided time reference. Perhaps one of the most intriguing features of the AMC is its reconfigurable programming. Unlike many other computers, the AMC can be reprogrammed up until final integration, under electrical control, no de-integration is required. This versatility can save thousands of dollars in any application. The AMC can also "save" data to its non-volatile memory, giving the AMC enough "smarts" to finish a task when interrupted by power removal, which is expected to occur at several points during the Deep Space II mission.

**Applicability**

Potential to support numerous applications where modest amounts of processing are required in dimensionally-constrained and/or remote locations for a minimal size, weight, and power consumption. Such applications include motor controllers, cryocooler refrigerator controllers, distributed health and status monitoring systems, configuration management processors, safety interlock protocol management, security systems, indoor weapons computer, space probe control computer, beacon processor, jet engine control. Will be useful in large satellites and high-performance systems as well, since those systems also have needs for lower-tier processing, which can be offloaded to one or more AMC units. Benefits to Deep Space Missions

Extremely high function-to-power, measured not just in the raw processing performance but in the degree of functionality accommodated. A single AMC can monitor and control a large variety of signals in low-level instrumentation. Multiple units can be employed with less size, weight, and power penalty than a single copy of any other system in its class. It can operate with extreme cold, radiation, and shock, and new versions can be quickly developed with much higher radiation tolerance.
