COMPOSITION AND PROCESS FOR RETARDING THE PREMATURE AGING OF PMR MONOMER SOLUTIONS AND PMR PREPREPS

Inventors: William B. Alston, Medina; Gloria S. Gahn, Columbia Station, both of Ohio

Assignee: The United States of America as represented by the Administrator of the National Aeronautics and Space Administration, Washington, D.C.

Patent Number: 6,103,864
Date of Patent: Aug. 15, 2000

The polyimides are derived from solutions of at least one low-boiling organic solvent, e.g. isopropanol containing a mixture of polyimide-forming monomers. The monomeric solutions have an extended shelf life at ambient (room) temperatures as high as 80° C. and consist essentially of a mixture of monoalkyl ester-acids, alkyl diester-diacids and aromatic polyamines wherein the alkyl radicals of the ester-acids are derived from lower molecular weight aliphatic secondary alcohols having 3 to 5 carbon atoms per molecule such as isopropanol, secondary butanol, 2-methyl-3-butanol, 2 pentanol or 3-pentanol. The solutions of the polyimide-forming monomers have a substantially improved shelf-life and are particularly useful in the aerospace and aeronautical industry for the preparation of polyimide reinforced fiber composites such as the polyimide cured carbon composites used in jet engines, missiles, and for other high temperature applications.

COMPOSITION AND PROCESS FOR RETARDING THE PREMATURE AGING OF PMR MONOMER SOLUTIONS AND PMR PREPREGS

ORIGIN OF THE INVENTION

The invention described herein was made by employees of the United States Government and may be manufactured and used by or for the Government for governmental purposes without the payment of any royalties thereon or therefor.

BACKGROUND OF THE INVENTION

1. Field of the Invention

This invention relates to stable organic solutions of polynimide-forming monomers having improved shelf-life and more specifically to the process of manufacturing, shipping, handling, storage and the fabrication layup of all types of PMR (polymerization of monomeric reactants) polyimide-forming monomeric solutions and the PMR polyimide prepregs derived therefrom without adversely affecting subsequent processability at cure temperature of the PMR resins and PMR composites.

2. Description of Related Prior Art

Polymerization of Monomer Reactants (PMR) to obtain polynimides is an important class of ultra high performance composite resins. Polynimide graphite fiber reinforced composites are increasingly used in various aircraft engine components, which operate at temperatures ranging up to 371°C for thousands of hours. For example, PMR-15 is one of the best known and most widely used PMR polyimide.

PMR-15 attributes include relatively easy processing, substantially lower costs, and excellent property retention at elevated temperatures, compared to other commercially available high temperature resin materials.

The preparation of polynimide from mixtures of monomeric diamines and esters of polycarboxylic acids is disclosed, for example, in U.S. Pat. No. 3,745,149. Patentee disclosed that polyimides can be processed from a mixture of monomeric reactants using lower (primary) alcohols to form a monomeric mixture of monomeric diamines and esters of polycarboxylic acids, which at high temperature polymerizes to a polyimide. This procedure was the evolution of the terminology PMR (polymerization of monomeric reactants). The initial concept of using lower (primary) alcohols to prepare methyl or ethyl ester-acids remains in use as originally disclosed in the art over the last twenty-five years.

Subsequently, however, few PMR patents have issued that improve over the prior art and generally these patents required a new “wrinkle” such as the use of monofunctional additives or new formulations using new dianhydrides, diamines or endcaps. These prior art patents are still using additives or new formulations using new dianhydrides, required a new “wrinkle” such as the use of monofunctional ester-acids in contrast to the benefits obtained by the use of the higher (secondary) ester-acids in PMR Extended Shelf Life Technology.

The major disadvantages of the state-of-the-art PMR technology, as practiced commercially today, are the limited shelf life of the monomeric solutions at ambient (room) temperatures, the short working outlife time, and an extremely high sensitivity toward premature aging at temperatures even slightly above room temperature. The disadvantages cause premature polymerization during all phases of PMR usage such as in synthesis, manufacturing, shipping, handling, storage, and fabrication layup/processing. The PMR technology employed today still uses the lower (primary) methyl and ethyl diester-diacid and ester-acid of the dianhydride and nadic anhydride endcap respectively. This methyl and ethyl ester technology is PMR’s inherent weakness in that imidization proceeds rapidly at about room temperature, thereby quickly aging all PMR types of polyimides such that aged solutions and prepregs expire with limited shelf life within one to three weeks at room temperature thereby being unprocessable with autoclave fabrication techniques. The engineering solution, as opposed to the chemical solution, to premature aging of PMR solutions and prepregs has been through rigorous handling requirements via strict manufacturing temperature control, overnight air shipment in dry ice, freezer storage of received PMR materials and stringent quality control governing allowed outlife usage time and freezer storage time; all of which significantly adds to the final cost of PMR composites.

Another disadvantage of the state-of-the-art PMR technology is the use of toxic lower (primary) methanol and ethanol for esterification and as the solvent for PMR monomer solution preparation and PMR prepreg manufacturing. These primary alcohols create highly toxic volatiles for both the manufacturer and user to control. In comparison, the PMR Extended Shelf Life Technology of this invention only uses the higher (secondary) and much less toxic isopropyl alcohol for the esterification and solvent in the PMR monomer solution preparation and PMR prepreg manufacturing. The evidence of reduced toxicity and increased safety are a lower odor threshold, well before you reach a much higher allowed threshold limit value, an increased autoignition temperature and narrower flammability limits along with less serious medical problems of overexposure in the use of isopropanol, for example, in comparison to the use of methanol or ethanol.

The PMR extended shelf life technology of this invention is based on a chemical solution to significantly retard aging of PMR solutions and PMR prepregs, rather than an engineering solution of rigid temperature control as evolved and still practiced in present PMR technology. The chemical solution to these problems is the use of the higher (secondary) C3 to C5 alcohols, e.g. isopropyl for esterification of the anhydride endcaps and dianhydride monomers.

SUMMARY OF THE INVENTION

This invention relates to novel compositions of matter and to the process of using higher (secondary) C3 to C5 ester-
acids of monoanhydrides and higher (secondary) C₃ to C₅
diester-di acids of numerous dianhydrides, both formed from
C₃ to C₅ secondary aliphatic alcohols, in preparing the
polyimide-forming solution of monomers. One of the
preferred compositions and processes relates to the use of the
higher (secondary) isopropyl ester-acid of nadic anhydride
and the isopropyl diester-di acids of numerous commercially
available dianhydrides, e.g. BTDA, 6FDA, PMDA, ODPA,
BPDA, etc. Preferably, the isopropyl ester-acids and iso-
propyl diester-di acids are mixed in solution with C₃ to C₅
secondary aliphatic alcohols and aromatic polyamines such
as the diamines to form PMR monomer solutions, which
subsequently form addition cured PMR resins at higher cure
temperatures.

The polyimides of this invention are derived from solu-
tions of low-boiling organic solvents and a mixture of
polyimide-forming monomers. The solutions of the
polyimide-forming monomers are characterized as having
an improved or extended shelf-life at ambient (room)
temperatures, i.e. stable solutions at temperatures ranging up
to about 80°C and comprise effective amounts of (a) at least
one mono-alkyl ester-acid having the formula:

\[
R_3\text{O--C} = \text{O--C} = \text{OR}_3
\]

wherein \( R_3 \) is a lower secondary alkyl radical of 3 to 5
carbon atoms, and \( R_1 \) is a divalent radical selected from the
Group consisting of alkyl, substituted alkyl, aryl and sub-
stituted aryl radicals, and

(b) at least one diester-diacid or an isomer thereof having
a formula selected from the Group consisting of

\[
R_1\text{O--C} = \text{O--C} = \text{OR}_1
\]

wherein \( R_4 \) is a tetravalent radical selected from the Group
consisting of naphthalene, benzene, and biphenyl radicals, \( R_1 \)
is the same or a different lower secondary alkyl radical of
3 to 5 carbon atoms, and \( X \) is a divalent radical selected from
the Group consisting of

\[
\text{C} = \text{O, CF}_3, \text{ CF}_2, \text{ C--OH, phenyl, C--CF}_3
\]

(c) at least one aromatic polyamine selected from the
Group consisting of aromatic diamines, aromatic
trimines, aromatic tetraamines and mixtures thereof in
any proportion.

The organic solutions of polyimide-forming monomers of
this invention can be heated to temperatures ranging from
about 250°C to 400°C, to obtain crosslinked polyimide
resins having average molecular weights in excess of
10,000. These polyimide resins can be formed into various
shapes and sizes in an autoclave or molding equipment e.g.
polyimide impregnated carbon fibers for use in high tem-
perature applications.

Accordingly, it is an object of this invention to improve
the room temperature storage stability of PMR monomer
solutions and PMR prepregs without adversely affecting the
processability of PMR polyimide composites.

It is another object of this invention to provide organic
solutions of polyimide-forming monomers and a process of
preparing said monomeric solutions for use in preparing
polyimide resins and polyimide prepregs.

It is still another object of this invention to provide a
mixture of polyimide-forming monomers that retards the
ambient (room) temperature reactivity of PMR solutions and
PMR prepreg materials. This improvement provides a wide
safety margin against mishandling of PMR solutions and
prepregs by significantly retarding the premature aging and
the expiration of the PMR solutions shelf life.

It is a further object of this invention to reduce the solvent
toxicity, limit the solvent flammability, provide higher autoi-
gnition temperatures, and lower the odor threshold of the
polyimide-forming monomeric solutions compared to the
state-of-the-art and to improve other health issues by using
polyimide-forming monomeric solutions that are less toxic.

These and other objects of this invention will become
apparent from a further and more detailed description of the
invention as follows.

DESCRIPTION OF THE PREFERRED
EMBODIMENTS

The PMR extended shelf life technology of this invention
is directed to a composition of matter comprising a
polyimide-forming monomeric solution consisting essen-
tially of, for example, at least one aromatic polyamine and
a C₃ to C₅ secondary alkyl ester such as an isopropyl ester
of nadic anhydride and at least one dianhydride preferably
selected from the Group consisting of 3,3',4,4'-
benzophenone tetracarboxylic dianhydride (BTDA); 1,1,1,
3,3,3-hexafluorotripropyleno bisphthalic acid dianhydride
(HFDA or 6FDA); 1,2,4,5-pyromellitic dianhydride
(BTDA); 3,3',4,4'-oxydiphthalic dianhydride (ODPA) and
3,3',4,4'-biphenylenetricarboxylic dianhydride (BPDA) con-
verted to the corresponding diester-diacid and to the pro-
cesses for preparing the ester-acid (and other mono ester-
acid endcaps) and the diester-diacids of various other
aromatic dianhydrides such as BTDA, 6FDA, PMDA,
ODPA, and BPDA.
More specifically, the monomeric solutions of the polyimide-forming monomers having an extended shelf life can be illustrated by using the C₃ to C₅ secondary aliphatic alcohols such as isopropanol, secondary butanol, 2-methyl-3-butanol, 2-pentanol or 3-pentanol; the preferred being isopropanol to form the esters and diesters of this invention as follows:

mono isopropyl ester-acids

![Chemical structure of mono isopropyl ester-acids]

isopropyl nadic ester

from

nadic anhydride

monoisopropyl phthalate

from

phthalic anhydride

monoisopropylphenylethynyl phthalate

from

as a 3,3': 3,4' and 4,4'-diester isomer mix

from

X= C=O(BTDA), CF₃-C-CF₆(6FDA), O(ODPA) and nil (BPDA)

As a specific example, the mono ester-acids and diester-diacids in combination with at least one aromatic polyamine are mixed in solution with a C₃ to C₅ secondary aliphatic alcohol as the solvent, e.g. 10% to 80% and preferably 30% to 60% by weight of isopropanol alcohol, and heated to temperatures ranging from about 500°F to 750°F to form the cured corresponding polyimides, as illustrated:
In the above example, the R₂ and R₃ are either the same or different secondary alkyl radicals derived from C₃ to C₇ lower secondary aliphatic alcohols, and R₄ is a tetravalent aryl radical.

The original PMR (Polymerization of Monomer Reactants) technology was developed in the early 1970's as a means of producing large void free polyimide fiber composites. The principal resin in the PMR family, PMR-15, has been commercially available since the late 1970s and is regarded as the industry standard for aircraft engine applications for long term use at temperatures ranging up to 500°F. The PMR-15 components are currently being used in both military and commercial aircraft engines. More recent adaptations of the PMR approach to high temperature polyimides can be found in such resin systems as PMR-II (a 1977 IR-100 Award Winner), AFR-700, TRW-800, and RP-46 (a 1992 R&D 100 Award Winner). Presently, the PMR process uses methyl or ethyl ester-acid monomers. However, work at the NASA Lewis Research Center clearly found that resin solutions and prepregs made with PMR resins have limited shelf life at room temperature. Research at NASA Lewis has determined that this is due to the premature formation of low molecular weight imides. Formation of these aging products adversely affects the handling and autoclave processability of PMR resin solutions and the prepregs. Presently, this aging process can be retarded only by storage of these materials at freezer temperatures. These PMR resin solutions and the prepreg therefrom must also be packed in dry ice and shipped overnight in order to minimize the formation of the aging products. This procedure results in a substantial cost for the handling and shipping of these materials.

However, recent research efforts have led to the development of PMR resins that have an improved shelf life, both as PMR monomer solutions and as PMR prepregs. It was found that this new extended shelf life technology was based upon the use of only aliphatic secondary alcohols having the 3 to 5 carbon atoms such as isopropyl alcohol rather than the methyl or ethyl ester-acids in PMR monomer formulations. Kinetic studies performed at the NASA Lewis Research Center discovered that the rate determining step in the formation of polyimides, as well as the imide-forming solution and prepreg aging products, via the PMR process, is the conversion of the methyl or ethyl ester-acids into anhydrides. The use of the bulkier isopropyl ester-acids, however, significantly retards the rate of anhydride formation which, in turn, limits the formation of undesired solution and prepreg aging products. The secondary isopropyl ester-acids, for example, were also shown to be the only secondary ester-acids that vastly improved the shelf life without unduly further complicating the composite processability. The use of this new chemistry to existing PMR technology increases the room temperature storage life of PMR solutions and prepregs by over an order of magnitude. Thus, the PMR extended shelf life technology eliminates the need for dry ice shipping and freezer storage of PMR materials. The PMR fiber composites prepared with extended shelf life prepregs retain the excellent thermo-oxidative stability and thermo-mechanical strengths equivalent to those made from the current commercially available PMR prepregs.

There are a variety of experimental new and previously developed PMR-type polyimides that compete with each other on the basis of material cost versus desired use temperature such as the nonfluorinated polyimides (DuPont KIII', PMR-15, RP46) at moderate cost for 500 to 600°F long term use, to the fluorinated polyimides (PMR-II, VCAP, AFR700, DuPont Avimid N) at high cost for 700°F shorter term use temperatures, to the difficult-to-process nonfluorinated polyimides (TRW-800) at moderate cost for 800°F very short term applications. The PMR extended shelf life technology of this invention was not developed to replace or compete with any of these PMR type materials; rather the development was to enhance the utility of all current and future PMR polyimides by allowing a significantly longer shelf life at lower storage and manufacturing temperatures (freezer to hot melt manufacturing temperatures) in order to prevent premature PMR aging during long term storage and manufacturing. Without the PMR extended shelf life technology of this invention, the current state-of-the-art PMR polyimide products will age at least 10× faster over a wide range of storage temperatures (freezer to room temperature) and manufacturing temperatures (hot melt prepregging up to 80°C) as shown by both formation of soluble aging products (seen by high pressure liquid chromatography) and by formation of precipitates and/or phase separations (highly visible events well past the PMR solution shelf life manufacturers desire).

As more specifically shown in the following Table I, the PMR extended shelf life technology of this invention provides the following benefits: (a) 10-30× increase in room temperature shelf life of PMR solutions making PMR materials more friendly to use, (b) lowers odor threshold to a much safer limit, the opposite of current state-of-the-art methanol based PMR technology, (c) reduced cost and
complexity of transporting and storing PMR materials by allowing room temperature shipping/handling/storage while current state-of-the-art PMR technology requires dry ice shipping and freezer storage, (d) negligible sensitivity to handling/shipping mistakes due to the vastly retarded aging at elevated temperatures and (e) increased applicability for hot melt prepreg manufacturing due to significant reduction in polymerization at hot melt temperatures (up to 80 °C. (176 ° F.) for short times).

*Time to a visible event = precipitation or phase separation. Not all PMR's do this as their aging products may only be seen by high pressure liquid chromatography because the aging products are still soluble or kept in solution by adding other solvents (which complicates composite processability). **PMR solutions age faster than PMR prepregs at room temperature due to increased mobility, but at elevated temperature prepreg ages faster as increased mobility and higher monomer concentration increases aging rate.*

The PMR extended shelf life technology of this invention is founded on the use of C3-C5 secondary alcohols in preparing the ester-acids and the use of C3-C5 secondary alcohol solvents which is an improvement over state-of-the-art methyl ester-acids and methanol solvent. Specifically, the improved shelf life reduces or eliminates the need for low temperature transportation and storage while providing a safe prepreg that is still well below the safety allowed Threshold Limit Value (TLV) when the isopropanol is smelled at its odor threshold. The opposite is the situation for the current use of the methanol or ethanol based PMR technology.

The lack of aging for extended storage life PMR materials also means that variation in the batch-to-batch manufacturing of PMR resins can be significantly lessened which would provide benefits in consistent processability (the material is identical each time before processing) resulting in reduced scrap rates in comparison to the current PMR technology. The current PMR technology low scrap rate and consistent processability are attained by the composites industry only by use of low temperature shipping, handling, and storage specifications during manufacture and processing of PMR prepregs. These specifications include rigid quality control via high pressure liquid chromatography for the formation of the premature imide aging products which the new PMR extended shelf life technology retards from forming.

The application of the extended shelf life technology of this invention applies to all of the non-toxic and current PMR polyimide monomeric solutions and prepregs, because this technology is general to retarding the rate determining step (anhydride formation) in the low temperature aging of all PMR materials. The extended shelf life technology can be used for all types of polyimides formed via the PMR process that has been developed over the past quarter of a century for aerospace and aeronautical PMR resin and PMR composite applications such as currently in jet engine, missile and other high temperature composite applications. This technology does not expand on the applications, rather it enhances the PMR material available for these applications.
Some applications not currently optimized or available with PMR technology are applications requiring longer shelf life or higher manufacturing temperatures such as stable PMR material repair kits with long term expiration dates now possible and hot melt PMR prepgs that now would not age during the hot melt manufacturing process (done typically for short finite times up to 80°C (176°F.). Both of these applications now are more feasible due to the proven long term shelf life at storage times and temperatures for which the current methyl or ethyl ester PMR technology does not meet the requirements. Additionally, the general nature of the extended shelf life technology of this invention also makes it applicable to the newer PMR resins now under development.

The following are some specific examples of tetracarboxylic acid dianhydrides suitable for practicing this invention including:

- 2,3,3',4'-benzophenonetetracarboxylic acid dianhydride
- 3,3',4,4'-benzophenonetetracarboxylic acid dianhydride
- 2,2',3,3'-benzophenonetetracarboxylic acid dianhydride
- 2,3,3',4'-biphenyltetracarboxylic acid dianhydride
- 3,3',4,4'-biphenyltetracarboxylic acid dianhydride
- 2,2',3,3'-biphenyltetracarboxylic acid dianhydride
- 4,4'-isopropylidenediphthalic anhydride
- 3,3'-isopropylidenediphthalic anhydride
- 4,4'-oxydiphthalic anhydride
- 4,4'-thiodiphthalic anhydride
- 4,4'-ethyldenediphthalic anhydride
- hexafluorisopropylidene bisphthalic anhydride (6FDA), phenyltrifluoroethylidene bisphthalic anhydride (3FDA), 2,3,6,7-naphthalenetetracarboxylic acid dianhydride
- 1,2,5,6-naphthalenetetracarboxylic acid dianhydride benzene-1,2,3,4-tetracarboxylic acid dianhydride
- pyrazine-2,3,5,6-tetracarboxylic acid dianhydride
- thiophene-2,3,4,5-tetracarboxylic acid dianhydride, and the indicated esters thereof.

These anhydrides and esters thereof and methods for their preparation are disclosed in U.S. Pat. No. 3,745,149 and U.S. Pat. No. 3,856,752, the disclosures of which are incorporated herein by reference.

In preparing the polyimide-forming solutions of this invention, various polyfunctional aromatic amines, including the diamines, triamines and tetraamines and mixtures thereof are used with the alkyl ester-acids and diester-di acids. The preferred polyfunctional amines include the diamines, e.g. aromatic diamines containing at least one benzene ring and preferably two benzene rings including:

- para-phenylenediamine
- meta-phenylenediamine
- 4,4'-diaminodiphenylmethane
- 4,4'-benzidine
- 4,4'-diaminodiphenyl sulfide
- 4,4'-diamino-diphenyl sulfone
- 3,3'-diamino-diphenyl sulfone
- 1,5-diamino-naphthalene
- bisaniline-m-xylidene (BAX)
- bisaniline-p-xylidene (BAX)
- bisaniline-p-benzyl carbonyl (COBAX)
- 3,3'-diaminobenzophenone
- 4,4'-diaminobenzophenone
- 3,3'-diaminodiphenylether
- 3,4'-diaminodiphenylether
- 4,4'-diaminodiphenylether
- 4,4'-diaminodiphenylmethane
- 3,3'-dimethoxy benzidine
- 2,2':dimethylbenzidine
- 3,3'-dimethyl benzidine and triamines such as
- 1,3,5-triaminobenzene
- 2,4,6-triamino-s-triazine
- 4,4'4'-triaminotriphenylmethane
- 4,4'-triaminotriphenylcarbinol

Monoamine endcaps used to replace the alkyl acid-ester endcaps include, for example, mono amines such as 3- or 4-aminophenyl acetylene (APA), 3 or 4-pentylethynylaniline (PEA) and 3 or 4-amino styrene (PAS) having the formulae:

```
H2N\_2
\_c\_-C\_\_C\_CH\_3
```

This embodiment of the invention reverses the molar ratio, N diester-diacid, N+1 polyamine and 2 alkyl ester acid endcap to molar ratio N polyamine, N+1 diester-diacid and 2 monoamine endcaps.

This embodiment uses an endcap that contains an amine group rather than an anhydride group to be esterified, thereby eliminating the use of the isopropyl ester of nadic anhydride. Here the embodiment is to use the reverse ratio as N moles aromatic diamines, N+1 moles isopropyl diester-diacids of the dianhydride monomer and from about 0.8 to 2.2 moles of the monoamine endcap, but 2 moles is generally preferred as a monofunctional crosslinkable primary aromatic amine.

Another embodiment of this invention is the use of an unreactive non-crosslinkable endcap, such as aniline or isopropyl ester of phthalic anhydride, or slight excess of isopropyl diester-diacid of the dianhydride to control at N>20 for the preparation of high molecular weight linear condensation polyimides. Another embodiment is the use of less than 2 moles (e.g. only one) of isopropyl nadic ester as endcaps, leaving the excess diamine as the other endcap. An example of this is AFR700. It consists of one mole of isopropyl nadic ester, N moles of isopropyl diester-diacid of
EXAMPLE 6

Assemble 12 3\times 8 inch plies into a stack and preheat them in a tray with glass 3\times 8 inch glass cloth top and bottom to 400° F. for 1 hour to imidize and remove solvents. Place ply stack in a 3\times 8 inch matched metal die, heat to 450° F., apply 1000 psi and continue to 600° F. Keep at 600° F. 2 hours in press, cool, remove finished laminate.

STANDARD COMPRESSION MOLDING CYCLE

iPr/iPr PMR-15 in 100% iPrOH sample calculations needed to determine resin flow (bleed) during compression processing using prepregs stored six months at room temperature. Before staging:

wt. of laminate and bottom porous = 60.21 g
wt. of laminate = 59.11 g

Top = 10.17 g - 9.69 = 0.48 g
bottom = 10.69 g - 9.52 g = 1.17 g

Volatiles = 59.11 - (48.28 + 0.48) = 9.18 g
% volatiles = 15.53% % resin flow = 3.42%

After Staging:

Laminate weight = 49.28 g

Top = 10.17 g - 9.69 = 0.48 g
bottom = 10.69 g - 9.52 g = 1.17 g

Volatiles = 59.11 - (48.28 + 0.48 + 1.17) = 9.18 g
% volatiles = 15.53% % resin flow = 3.42%

After Processing at 600° F./2 hr.:

Laminate weight = 47.68 g
Wt. of bleed = 0.2715 g

% resin flow = \frac{0.2715}{48.28} \times 100% = .5623%
% Volatiles = \frac{48.28 - (47.68 + 0.2715)}{48.28} \times 100% = .68%

Postcured Weight = 47.54 g

Preparation for Autoclave Heat Pressing

Freecoat 3\times 8 plates and frame—let dry. Place 8\frac{1}{2}\times 8\frac{1}{2}" nonporous (Teflon) over bottom of large frame. Cut 3\times 8" sheets of: 4 glass cloth, 1 nonporous, 2 porous. Weigh these 3\times 8" pieces separately except glass cloth weigh 2 at a time. Keep pieces for top and bottom of laminate separate. Place 3\times 8" frame coated side down then layers in this order: 2 glass, 1 porous and 12 plies (weigh these together), 1 porous, 2 glass, 1 nonporous. Put plate on top coated side down. Put two glass cloths 8\frac{1}{2}\times 8\frac{1}{2}" on top of plate. Place high temperature adhesive around edge of large frame. Place Kapton film on top. Cut the excess Kapton away from frame. Place part top of frame on and place clamps on 3 to a side. Place thermocouple in hole on side of frame. Place frame in press. Attach vacuum tube and plug in thermocouple. Pull a vacuum on the frame. Set stops on a piece of glass cloth on frame. Lower the press. Autoclaving—Heat Press

Get temperature up to ~125° F., rate of 5° F./min., at 15 mmHg and then hold at that temperature for 30 minutes (by

shutting off temperature control). Turn temperature control on again (set at 250° F.). Record the temperature at 3 minute intervals (trying to keep rate at 5° F./min.). As the temperature nears 250° F. begin to move the control up in 20–30° F. increments. At 300° F., close the valve on the water vacuum to increase vacuum to ~72 mmHg. Heat to 400° F. and hold for 1 hour. After 1 hour set the pressure to 0, hit the open button, remove the stops and place a 3 inch\times 8 inch metal plate on the prepreg. Close. Set temperature at ~460° F. When the temperature reaches ~450° F., apply 270 psi pressure. Increase the temperature by 50° F. increments until 600° F. Hold at 600° F. for 2 hours. After 2 hours, shut off heat and vacuum pump. Let cool down. Remove laminate and weigh.

PMR II-50 monomer solution and prepreg preparation.

To prepare about 225 gms resin for 375 gms.

Graphite cloth at N + 9 PMR II = 50 wt._ = \frac{225}{50} = 0.4458 mole

6FDA=(9) (0.04458) (444.246)=178.179 gm in 274 gm isopropanol—dissolved in 5 hours—heat 1 hour more and cool as in example 3. Add 48.194 gm PPDA and 19.998 gm iPrNE. Slightly warm to dissolve and when in solution coat via a paint brush a T650-35 graphite cloth (30½ inch×52 inch). Let air dry and cut into 84 - 4×4 inch plies, using the edge scraps for characterization via Rheology, DSC, TGA, TMA, etc. The prepregs can be stored at room temperature up to 4 years and can be still autoclave processed satisfactorily.

The final process temperature time is about 700° F./1 hr. compared to PMR-15 at 600° F./2 hr.

PMR II-50 IN AUTOCLAVE MOLDING

iPr/iPr PMRII-50 IN 100% iPrOH calculations needed to determine resin flow (bleed) during autoclave processing using prepreg stored twelve months at room temperature. Before staging:

wt. of laminate and bottom porous = 57.18 g

VCAP-75 MONOMER SOLUTION AND PREPRREG PREPARATION

The isopropyl nadic ester (iPrNE) was changed for a different endcap, 4-aminostyrene. This changes molar ratio from N/N+1/2 for PMR II-50 to N+1/N/2 where N=14 for VCAP-75 (due to endcap is an amine instead of ester-acid).

For same size graphite cloth as for PMR II-50, 225 gm resin for 375 gm cloth.

225/7874 (VCAP mole wt)=0.02858 moles resin desired
iPr6FDE=(0.02858) (10) (mole wt.)=241.8317 gm
PPDA=(0.02858) (N=9) (mole wt.=108.44)=43.2948 gm
4 amino styrene=(0.02858) (2) (mole wt.=6.807 gm)
Esterify (10) (444.246) (0.02858)=190.335 gm of 6FDA in 293 gm isopropanol. (Use 6FDA after previously drying for 375 gm cloth.

45 mixture of polyimide-forming monomers consist essentially of:

(a) at least one mono-alkyl ester-acid having the formula:

(b) at least one diester-diacid and isomers thereof having the formula selected from the Group consisting of:

wherein R 2 is a lower secondary alkyl radical of 3 to 5 carbon atoms, and R 3 is a divalent radical selected from the Group consisting of alkyl, substituted alkyl, aryl and substituted aryl radicals, and

(c) at least one aromatic polynime selected from the Group consisting of aromatic diamines, aromatic triamines, aromatic tetraamines and mixture thereof.

2. The stable monomeric solution of claim 1 wherein the mixture of polyimide-forming monomers consist essentially of about N moles of the diester-diacid, N+1 moles of the aromatic diamine and about 0.5 to 2.2 moles of the alkyl ester-acid wherein the value of N ranges from about 2 to 30.

3. The stable monomeric solution of claim 2 wherein the organic solvent is a lower molecular weight aliphatic secondary alcohol having 3 to 5 alkyl carbon atoms.

4. The stable monomeric solution of claim 2 wherein R 2 and R 3 are derived from either the same or different alkyl secondary alcohols having 3 to 5 alkyl carbon atoms.

5. The stable monomeric solution of claim 2 wherein R 2 and R 3 are derived from either the same or different alkyl
secondary alcohols selected from the Group consisting of isopropyl, secondary butyl, 2-methyl-3-butyl, 2-pentyl and 3-pentyl alcohols.

6. The stable monomeric solution of claim 5 wherein the secondary alcohol is isopropyl alcohol.

7. The stable monomeric solution of claim 1 wherein the mixture of polyimide-forming monomers consist essentially of about N moles of the aromatic polyamines, N+1 moles of the diester-diacids and the alkyl ester endcap is replaced by 0.8 to 2.2 moles of at least one of monoamine endcap wherein the value of N ranges from about 2 to 30.

8. The stable monomeric solution of claim 1 wherein R₂ and R₃ are either the same or different radicals derived from secondary aliphatic alcohols having 3 to 5 carbon atoms.

9. The stable monomeric solution of claim 1 wherein R₁ is a divalent radical derived from nadic anhydride.

10. The stable monomeric solution of claim 2 wherein R₄ is a tetravalent benzene radical.

11. The stable monomeric solution of claim 2 wherein R₄ is a tetravalent biphenyl radical.

12. The stable monomeric solution of claim 2 wherein R₁ is a divalent radical derived from nadic anhydride and R₄ is a tetravalent radical derived from pyromellitic dianhydride.

13. The stable monomer solution of claim 2 wherein R₁ is a divalent radical derived from nadic anhydride and X is a carbonyl group derived from benzophenone tetracarboxylic dianhydride.

14. The stable monomers solution of claim 2 wherein R₁ is a divalent radical derived from nadic anhydride and X is a hexafluoroisopropylidene group derived from hexafluoroisopropylidene bisphthalic dianhydride.

15. A process of preparing polyimides which comprises heating a monomeric solution of at least one low boiling organic solvent comprising a mixture of polyimide-forming monomers; said solution of polyimide-forming monomers having an extended shelf-life at temperatures ranging up to about 80°C which consist essentially of:

(a) mono-alkyl ester-acid having the formula:

(b) at least one diester-diacid and isomers thereof having the formula selected from the Group consisting of:

and, wherein R₄ is a tetravalent aryl radical selected from the Group consisting of naphthalene, benzene, and biphenyl radicals, R₅ is a secondary alkyl radical having 3 to 5 carbon atoms, and X is a radical selected from the Group consisting of C=O, CF₃-C-CF₃, CHOH, phenyl-C-CF₃, CH₂, CH₃-C=CH₂, and —O—, and

(c) at least one aromatic polyamine selected from the Group consisting of aromatic diamines, aromatic triamines, aromatic tetraamines and mixtures thereof.

16. The process of claim 15 wherein the monomeric solution of polyimide-forming monomers is heated to temperatures ranging from about 250°C to 385°C.

17. The process of claim 15 wherein the mixture of polyimide-forming monomers consist essentially of about N moles of the diester-diacid, N+1 moles of the aromatic polyamine 0.8 to 2.2 moles of the alkyl ester-acid wherein the value of N ranges from about 2 to 30.

18. The process of claim 15 wherein the mixture of polyimide-forming monomers is a solution consisting essentially of about N moles of the aromatic polyamines, N+1 moles of the diester-diacids and the alkyl ester endcap is replaced by 0.8 to 2.2 moles of a monoamine endcap wherein the value of N ranges from about 2 to 30.

19. The process of claim 15 wherein at least one of the organic solvents is a lower molecular weight aliphatic secondary alcohol having 3 to 5 alkyl carbon atoms.

20. The process of claim 15 wherein R₂ and R₃ are derived from either the same or different alkyl secondary alcohols having 3 to 5 alkyl carbon atoms.

21. The process of claim 15 wherein R₂ and R₃ are derived from either the same or different alkyl secondary alcohols selected from the Group consisting of isopropyl, secondary butyl, 2-methyl-3-butyl, 2-pentyl and 3-pentyl alcohols.

22. The process of claim 15 wherein R₁ is derived from nadic anhydride.

23. The process of claim 21 wherein R₂ and R₃ are the same radicals derived from lower secondary aliphatic alcohols of 3 to 5 carbon atoms.

24. The process of claim 21 wherein the secondary alcohol is isopropyl alcohol.

25. The process of claim 15 wherein R₄ is a benzene radical.

26. The process of claim 15 wherein R₄ is a biphenyl radical.

27. The process of claim 15 wherein X is a carbonyl derived from benzophenone tetracarboxylic dianhydride.

28. The process of claim 15 wherein X is a hexafluoroisopropylidene group derived from hexafluoroisopropylidene bisphthalic dianhydride.

29. Fibers impregnated with effective amounts of the polyimide-forming monomeric solution of claim 1 having an extended shelf-life at temperatures ranging up to 80°C.
30. The impregnated fibers of claim 29 wherein the fibers are selected from the Group consisting of glass, carbon, polyamide fibers and mixtures thereof.

31. The impregnated fibers of claim 29 wherein the polyimide-forming monomeric solution comprises a mono-secondary alkyl ester-acid derived from nadic anhydride and a secondary alkyl diester-diacid derived from pyromellitic dianhydride.

32. The impregnated fibers of claim 29 wherein the monoalkyl ester-acid of nadic anhydride is derived from isopropanol.

33. The impregnated fibers of claim 29 wherein the diester-diacid is derived from benzophenone tetracarboxylic dianhydride.

34. The impregnated fibers of claim 29 wherein the diester-diacid is derived from hexafluoroisopropylidene bisphtalic dianhydride.

35. A process of preparing polyimide reinforced fibers which comprises impregnating said fibers with effective amounts of the polyimide-forming monomeric solution of claim 1 and heating said impregnated fibers to curing temperatures.

36. The process of claim 35 wherein the reinforced fibers are selected from the Group consisting of glass, carbon, polyamide fibers and mixtures thereof.

37. The process of claim 36 wherein the fibers are carbon fibers.

38. Polyimide reinforced fibers obtained by the process of claim 35.

39. Polyimide-reinforced fibers obtained by the process of claim 36.

40. Polyimide-reinforced fibers obtained by the process of claim 37.
