CSC/MRJ Technology Solutions
NASA AMES Research Center
Background

- Computational Intensive Applications
- Fortran, C/C++
- Migration of codes to parallel computers
- Shared memory parallelization:
  - Multithreading
  - Compiler support via directives
- Distributed memory parallelization:
  - Requires explicit message passing, e.g. MPI
- Desire to generate message passing versions of existing sequential code
The CAPTools Parallelization Support Tool

- Developed at the University of Greenwich
- Transforms existing sequential Fortran code into parallel message passing code
  - Extensive dependence analysis across statements, loop iterations, and subroutine calls.
  - Partitioning of array data
  - Generation of necessary calls to communication routines

```
program Laplace
real u(100), v(100)
...
do 10 i = 2, 99
   u(i) = 0.5 * (v(i-1) + v(i+1))
end do
....
```

```
program PARALLELlaplace
real u(100), v(100)
...
CALL CAP_EXCHANGE(v, CAP_RIGHT,...)
CALL CAP_EXCHANGE(v, CAP_LEFT,...)
do i = CAP_LOW, CAP_HIGH
   u(i) = 0.5*(v(i-1) + v(i+1))
end do
....
```

Possible sources for errors:
- Wrong user information
- Tool makes mistake
Relative Debugging

- P1: version of a program that produces correct results.
- P2: version of the same program that produces incorrect results.
- Relative Debugging:
  - Compare data between P1 and P2 to locate the error.
  - P1 and P2 can possibly run on different machines, e.g., a sequential and a parallel architecture.
    - Applies directly to our situation.
Questions

- What data values should be compared?
  - Variables that have been determined as being incorrect and variables that define them.
- When during execution should they be compared?
  - Places where suspicious variables are defined.
- Where should data residing in multiple address space be compared?
  - Suspicious values from both executables written to file.
  - Debugger collects data from both executables.
  - Executables establish communication and compare data.
- How do we decide whether the values are correct?
  - Array checksums, element-by-element comparison, etc.
- How do we handle distributed data?
  - Array distribution information is necessary.
Main Players in the Prototype: The CAPTools Database

- The CAPTools Database:
  - Provides **variable definition information** across subroutines to determine which variables should be checked.
  - Provides **array distribution information** to determine how distributed data should be compared against undistributed data.

CAPTools Information:

sub1: var1: CAP1_LOW:CAP1_HIGH, 1:N
sub2: var2: 1:M, CAP1_LOW:CAP2_HIGH
Main Players in the Prototype:  
The Comparison Routines

- The comparison routines: inserted at entry and exit of suspicious routines to bracket error location.
- compit1: Inserted in sequential program S
  - Receives data from each processor from parallel program P1, P2, ...
  - Compares data to its own:
    - checksum, partial checksums, element-by-element
  - Calls special routine if discrepancy detected.
- compit2: Inserted in parallel program.
  - Sends local data to sequential process.

```
S
  ...
  subroutine sub1(var1)
  call compit1(var1)
  ...
  call compit1(var1)
  end

P1
  ...
  subroutine sub1(var1)
  call compit2(var1)
  ...
  call compit2(var1)
  end

P2
  ...
  subroutine sub1(var1)
  call compit2(var1)
  ...
  call compit2(var1)
  end
```
Main Players in the Prototype: Instrumentation Server and P2d2

- Instrumentation Server (IS):
  - Based on dyninstAPI which was developed at the University of Maryland
  - C++ library that provides API for runtime code patching,
  - Permits insertion of calls to comparison routines into a running program

- P2d2 debugger:
  - Developed at NASA Ames Research Center
  - Portable, scalable, parallel debugger
  - Client-Server architecture based on gdb
  - P2d2 coordinates the actions of the other players and provides user Interface
A Relative Debugging Session (1)
Behind the Scenes (1)

Behind the Scenes (2)

p2d2 indicates to user that difference was detected

- Run outside of debugger control
- Communicate with S

breakpoint trap if error is detected
A difference was detected in variable 'phi4' when exiting from function 'update'. The variable had tested equal when entering function 'update'.
Related Work

• GUARD

  – Relative Debugger for Parallel Programs
  – Developed at the Griffith University in Brisbane, Australia.
  – The debugger collects data from both executables and performs comparison.
  – Does not aim particularly at automatically parallelized programs.
  – Provides user commands like “assert” and “compare” for comparison.
  – Provides means for the user to describe array distribution.
Project Status and Future Work

- We have built a prototype of a relative debugging system for comparing serial codes and their tool produced counterparts.
  - Prototype runs on SGI Origin IRIX6.5
- We used dynamic instrumentation to minimize comparison overhead:
  - First timing experiments were inconclusive.
- We plan to modify the p2d2 user interface to support multiple computations executing simultaneously.
- Extend prototype to handle OpenMP programs.
