Since its founding, NASA has been dedicated to the advancement of aeronautics and space science. The NASA Scientific and Technical Information (STI) Program Office plays a key part in helping NASA maintain this important role.

The NASA STI Program Office is operated by Langley Research Center, the lead center for NASA’s scientific and technical information. The NASA STI Program Office provides access to the NASA STI Database, the largest collection of aeronautical and space science STI in the world. The Program Office is also NASA’s institutional mechanism for disseminating the results of its research and development activities. These results are published by NASA in the NASA STI Report Series, which includes the following report types:

- **TECHNICAL PUBLICATION.** Reports of completed research or a major significant phase of research that present the results of NASA programs and include extensive data or theoretical analysis. Includes compilations of significant scientific and technical data and information deemed to be of continuing reference value. NASA counter-part of peer-reviewed formal professional papers, but having less stringent limitations on manuscript length and extent of graphic presentations.

- **TECHNICAL MEMORANDUM.** Scientific and technical findings that are preliminary or of specialized interest, e.g., quick release reports, working papers, and bibliographies that contain minimal annotation. Does not contain extensive analysis.

- **CONTRACTOR REPORT.** Scientific and technical findings by NASA-sponsored contractors and grantees.

- **CONFERENCE PUBLICATION.** Collected papers from scientific and technical conferences, symposia, seminars, or other meetings sponsored or co-sponsored by NASA.

- **SPECIAL PUBLICATION.** Scientific, technical, or historical information from NASA programs, projects, and missions, often concerned with subjects having substantial public interest.

- **TECHNICAL TRANSLATION.** English-language translations of foreign scientific and technical material pertinent to NASA’s mission.

Specialized services that help round out the STI Program Office’s diverse offerings include creating custom thesauri, building customized databases, organizing and publishing research results...even providing videos.

For more information about the NASA STI Program Office, see the following:

- E-mail your question via the Internet to help@sti.nasa.gov
- Fax your question to the NASA Access Help Desk at (301) 621-0134

under contract NAS1-00135

December 2001
Summary

This report documents the results of a computational study done to compute the inviscid longitudinal aerodynamic characteristics of the Space Shuttle Orbiter for Mach numbers 10 and 15 at angles of attack of 40, 50, 55, and 60 degrees. These computations were done to provide limited aerodynamic data in support of the Orbiter contingency abort task. The Orbiter had all the control surfaces in the undeflected position. The unstructured grid software FELISA with the equilibrium air option was used for these computations. Normal force, axial force, and pitching moment coefficients were computed. The hinge moment coefficients of the body flap and the inboard and outboard elevons were also computed. These results were compared with data from Operational Aerodynamic Data Book (OADB) and those computed using the software GASP. The comparison with the GASP results showed excellent agreement in $C_L$ and $C_A$, and also in the flap and elevon hinge moment coefficients at all the points. The present axial force coefficients were smaller than those computed by GASP. Similar agreement was notice with the elevon and body flap hinge moments. There were noticeable differences between the present results and those from the OADB at angles of attack greater than 50 degrees.

Software

The present computations were done using the unstructured grid inviscid flow software FELISA. This software consists of unstructured surface triangulator, volume grid generator, and flow solvers. The flow solver can be run with any of the options including the perfect gas, equilibrium gases (air and Mars gas), and Mars real gas. More information about FELISA may be found in [1]. FELISA software has been successfully used for inviscid hypersonic flow computations, (See for example [2], [3], [4], and [5].) The present computations were done using the hypersonic flow solver with the equilibrium air option.

Grids

Two separate grids were used in these computations. The two grids had the same spacing distributions every where except near the nose of the Orbiter. Around the nose, the minimum spacing was 2 inches in the coarse grid, whereas it was reduced to 0.2 inches in the fine grid. This led to better capturing of the flow features near the nose of the Orbiter. A view of the two grids on the symmetry plane near the Orbiter nose is shown in Fig. 1 The information on these grids is given here:

<table>
<thead>
<tr>
<th></th>
<th>Fine Grid</th>
<th>Coarse Grid</th>
</tr>
</thead>
<tbody>
<tr>
<td>No. of Surface Points</td>
<td>91,895</td>
<td>64,365</td>
</tr>
<tr>

<td>183,786</td>
<td>128,726</td>
</tr>
<tr>
<td>No. of Tetrahedral Elements</td>
<td>10,950,214</td>
<td>7,979,561</td>
</tr>
<tr>
<td>No. of Nodes</td>
<td>1,855,685</td>
<td>1,350,843</td>
</tr>
</tbody>
</table>

Freestream Conditions

The freestream conditions for the two Mach number cases used in the present computations are as follows:
Figure 1: Comparison of the surface triangulations near the nose.
Mach Number | 10.0 | 15.0  
Velocity     | 10,552 ft/s | 15,679.05 ft/s  
             | (3217.2 m/s) | (4779.0 m/s)  
Temperature  | 463.7 °R    | 454.7 °R  
             | (257.6 K)    | (252.6 K)  
Density      | 5.28E-6 slugs/ft³ | 7.77E-6 slugs/ft³  
             | (2.7213E-3 kg/m³) | (4.0047E-3 kg/m³)  

The computed normal and axial forces, the pitching moment, the bodyflap hinge moment, and the elevon hinge moments were non-dimensionalized in the conventional way. The reference quantities used for this purpose are as follows:

<table>
<thead>
<tr>
<th>Coefficients</th>
<th>$C_N$, $C_A$, $C_m$</th>
<th>Flap H.M.</th>
<th>Elevon H.M.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reference Area (in²)</td>
<td>387,360</td>
<td>19,440</td>
<td>30,240</td>
</tr>
<tr>
<td>Reference Length (in)</td>
<td>474.72</td>
<td>81.0</td>
<td>90.7</td>
</tr>
</tbody>
</table>

The pitching moment reference point is located on the symmetry plane, 841.7 in. behind the nose and 38.5 in. above the longitudinal axis. The longitudinal axis passes through the nose of the Orbiter.

The hinge moment of the bodyflap was computed about the hinge line located at a distance of 1296 in. from the nose and 51 inches below the longitudinal axis. This hinge line is perpendicular to the symmetry plane.

The hinge moment of the elevon was computed in a similar manner. The elevon hinge line is located at a distance of 1151 in. from nose. The hinge line meets the symmetry plane at 76.652 in. below the longitudinal axis, and makes a dihedral angle of 5.229 deg.

Results

The computations were done on the NAS Origin 2000 parallel computers using 64 processors. The results are listed in Table 1. Similar computations had been done by Papadopoulos, P.E. et al, ([6]) assuming 5-species nonequilibrium air. Present results and the GASP results are shown plotted in Figures 2 - 8 along with the corresponding data from OADB. See [7]. It should be noted that the OADB and GASP results are for Mach 15.

Refining the grid near the Orbiter nose did not make any noticeable differences in the results at Mach 10. The differences in the results obtained using the coarse and the fine grids were less than 1%. The contribution of the nose to the aerodynamic coefficients is predicted adequately by the coarse grid. The fine grid, however, allowed better capturing of the sonic line on the symmetry plane (See Figure 5.)

Figures 4 indicates that the present values of $C_A$ are lower than both OADB data and the GASP results. This is the result of absence of skin friction in the present computations. At high Mach numbers and particularly at high angles of attack, the normal force is primarily due to the pressures on the windside of the vehicle. Inviscid flow computations adequately predict the flow over the windside surfaces. The OADB $C_m$ and $C_A$ values deviate from the FELISA computations as well as the GASP results at angles of attack greater than 50 degrees.

Hinge moments of the bodyflap, and the inboard and the outboard elevons were computed, and are listed in Table 2. Results are shown plotted in Figure 6 - 8. Also shown plotted in these figures are the hinge moment coefficients from OADB and those computed using the GASP software.

Table 1: Inviscid aerodynamic data for Mach 10 and 15.

Figure 2: Pitching moment coefficient
Figure 3: Normal force coefficient

Figure 4: Axial force coefficient
The OADB hinge moment coefficients curves have an inflexion point at about an angle of attack of 45 degrees. However, the computed data do not exhibit this trend. It may be observed that the FELISA results agree very well with the GASP results. The computed inboard elevon hinge moment coefficients agree with the OADB data upto an angle of attack of 60 degrees. The maximum difference is about 0.025 at $\alpha = 50$ degrees. The outboard elevon hinge moment coefficients agree with the OADB data only upto an angle of attack of 50 degrees. At angles of attacks greater than 50 degrees, the outboard elevon hinge moment coefficients continue to increase negatively, whereas the OADB data tend to level off. At $\alpha = 60$ degrees the difference between the computed and OADB data is 0.25. The computed bodyflap hinge moment coefficients agree with the OADB data except at an angle of attack of 60 degrees where the difference between the two is 0.05.
