Reduced Vector Preisach Model

Umesh D. Patel, Member, IEEE, Edward Della Torre, Fellow, IEEE

Abstract— A new vector Preisach model, called the Reduced Vector Preisach model (RVPM), was developed for fast computations. This model, derived from the Simplified Vector Preisach model (SVPM), has individual components that like the SVPM are calculated independently using coupled selection rules for the state vector computation. However, the RVPM does not require the rotational correction. Therefore, it provides a practical alternative for computing the magnetic susceptibility using a differential approach. A vector version, using the framework of the DOK model, is implemented. Simulation results for the reduced vector Preisach model are also presented.

Index Terms—Hysteresis modeling, Preisach model, vector magnetization modeling.

I. INTRODUCTION

The accurate characterization of magnetic processes requires a vector model of magnetic hysteresis. The classical Preisach model cannot adequately represent vector magnetic processes since it is inherently a scalar model. Several authors have modified the scalar Preisach model to include the vector features of a magnetic medium [1-3]. The Simplified Vector Preisach Model (SVPM) [1] was developed for computing the vector magnetization in response to a vector-applied field.

The SVPM is a coupled-hysteron model that exhibits both the saturation property and the loss property [1]. The vector magnetization is computed from the integration of the product of a state vector and a Preisach function and then performing the rotational correction. The state vector is computed using the selection rules determined by the applied field. The rotational correction term provides the cross-axis coupling effect of applied fields. This cross-axis coupling term makes it impossible to obtain an analytical closed form solution for the magnetic susceptibility.

This paper presents a Reduced Vector Preisach Model (RVPM) that does not require the rotational correction. The developed vector model uses modified selection rules for state vector calculation.

II. SIMPLIFIED VECTOR PREISACH MODEL

The SVPM computes the normalized irreversible magnetization components as the product of the rotational correction \( R(I_x, I_y, I_z) \), and the basic Preisach integrals \( I_j \),

\[
m_{ij} = R(I_x, I_y, I_z) I_j, \quad \text{for } j = x, y, \text{ or } z. \tag{1}
\]

In two dimensions, the output from those basic Preisach integrals \( I_j \) are computed as

\[
I_j = \int_{v_j}^{u_j} \mathcal{Q}_j p(u_j, v_j) \, du_j \, dv_j, \quad \text{for } j = x, y, \text{ or } z. \tag{2}
\]

where the up and down switching fields are \( u_j \) and \( v_j \), the normalized Preisach function \( p \), and the state function \( \mathcal{Q}_j \).

The rotational correction is given by

\[
R(I_x, I_y, I_z) = \sqrt{I_x^2 + I_y^2 + I_z^2} \tag{3}
\]

It was shown [1] that for any set of values of \( I_j, 1 \leq R \leq \sqrt{3} \), the rotation correction ensures the correct magnitude of the magnetization.

The normalized irreversible magnetization is computed as the vector sum of three basic Preisach models as

\[
m_I = R M. \tag{4}
\]

The irreversible magnetization can be computed as the vector sum

\[
M_I = M_s S m_I, \tag{5}
\]

where \( M_s \) is the saturation magnetization and \( S \) is the material squareness matrix defined as

\[
S = \begin{bmatrix}
S_x & 0 & 0 \\
0 & S_y & 0 \\
0 & 0 & S_z
\end{bmatrix} \tag{6}
\]

Thus, to simulate anisotropic media, this model can allow different values for the \( S \)'s along each of the axes and parameters in the basic Preisach models.

The normalized reversible magnetization components can be computed as

\[
m_{Rj} = a_j f(H_j) - a_j f(-H_j), \quad \text{for } j = x, y, \text{ or } z. \tag{7}
\]

where the \( a_n \) variables can be implemented with either a state-independent, magnetization-dependent, or state-dependent reversible magnetization as in the case of the scalar models.

The non-linear function \( f(H_j) \) is defined as
where $\xi$ is a model parameter that needs to be identified.

The reversible magnetization can be computed as a vector sum,

$$M_R = (1 - S)M_I + M_R,$$  

(9)

where $S$ is the squareness matrix defined in (6).

Then the total magnetization can be expressed as

$$M_T = M_I + M_R.$$  

(10)

## III. REDUCED VECTOR PREISACH MODEL

The Reduced Vector Preisach Model computes the normalized irreversible magnetization components using the basic Preisach integrals

$$m_j = \int \int \int \int Q_{ij} d\alpha_j dv_j d\nu_j, \text{ for } j = x, y, \text{ or } z.$$  

(11)

where the up and down switching fields are $\alpha_j$ and $\nu_j$, the normalized Preisach function $Q$, and the state function $\alpha$.

The state vector is computed by new selection rules summarized in Table I for the 2-D case. These rules differ from the SVPM case only at the corners. The subscript $d$ is used for the direction in which $Q_d$ is being computed. The subscript $c$ is used to indicate the cross direction. These new selection rules are defined such that no rotational correction is required for computing the magnetization [5].

Similarly, the irreversible magnetization, the reversible magnetization component and the total magnetization are computed using (5), (9) and (10) respectively.

The application of selection rules shown in Table II shows that at any point on the Preisach hyperplane, the square of the sum of the Cartesian components of the state vector obeys

$$Q_x^2 + Q_y^2 + Q_z^2 = 1.$$  

(12)

For the ellipsoidal magnetization behavior, the major remanence path must satisfy

$$m_{xR}^2 + m_{yR}^2 + m_{zR}^2 = 1.$$  

(13)

For sufficiently strong fields, the normalized reversible magnetization satisfies

$$m_{xR}^2 + m_{yR}^2 + m_{zR}^2 = 1.$$  

(14)

Therefore, the normalized total magnetization can be expressed as

$$m_{xT}^2 + m_{yT}^2 + m_{zT}^2 = 1.$$  

(15)

The important properties of the RV$^2$M can be summarized as:

- It is applicable to the anisotropic media as well as the isotropic media.
- It can be reduced to the scalar model if the applied field lies only along one of the principal axes and the magnetization initially lies along that axis. Also, the vector model will have all the properties of the scalar moving model.
- For both isotropic and anisotropic media, in the presence of large fields, the normalized irreversible magnetization and the normalized reversible magnetization trace out an ellipse.

## IV. SIMULATIONS

The RVPM is applied to an isotropic magnetic medium. For an isotropic medium, values for $\sigma_i$ and $\sigma_f$ are equal, and negligible compared to the average critical field $\overline{H_k}$. The material parameters used for simulations are: $\sigma_i = \sigma_f = 165$, $\overline{H_k} = 633$, $S = 0.57$, $M_S = 0.014127$, $\alpha = 33332.81$, $\xi = 0.0009$.

Simulations were carried out for the orthogonal component $H_R$ of the applied field of $1.1\overline{h_k}$, $1.4\overline{h_k}$ and $4\overline{h_k}$. The vector DOK model [7] is implemented based on the RVPM using the cobweb method [6] for computation speed. Figure 1 shows a plot for the magnetization angle versus applied field angle. It can be seen that the magnetization ratchets as the applied field rotates. For very large applied fields, the magnetization angle becomes equal to the applied field angle for all values.

Figure 2 shows the locus of the magnetization as the applied field is rotated. It is seen that as the field increases, the curves become rounder. The flattening of the loci close to 135 degrees and 315 degrees is a discretization error caused by the jump in the magnetization angle for the respective applied fields.

For an isotropic media, since the magnetization rotates faster than the applied field, the rotations of the magnetization need to be corrected using the correction rules defined in [8]. Applying these corrections for the applied fields as in Figure 1, the corrected magnetization angle vs. applied field angle is plotted as shown in Figure 3. Figure 4 shows the magnetization loci with corrections for an applied field rotation of 360 degrees. It is seen that the curves are more rounded.

## V. CONCLUSION

A simpler vector model is developed that does not require the rotational correction for computation speed. The elimination of the rotational correction makes it possible to implement the differential method, a very effective way to compute the magnetization. The simulation results show that the presented model represents isotropic media accurately. Further refinement of this vector model in terms of speed and accuracy is a topic of future research.

## ACKNOWLEDGMENT

We would like to thank Chitra Patel and Chandru Mirchandani for meaningful discussions and help. We also like to thank members of the Institute for Magnetics Research and in particular Dr. Lawrence Bennett and Dr. Ann Reimers for many useful discussions.
