July 2002
Since its founding, NASA has been dedicated to the advancement of aeronautics and space science. The NASA Scientific and Technical Information (STI) Program Office plays a key part in helping NASA maintain this important role.

The NASA STI Program Office is operated by Langley Research Center, the Lead Center for NASA's scientific and technical information. The NASA STI Program Office provides access to the NASA STI Database, the largest collection of aeronautical and space science STI in the world. The Program Office is also NASA's institutional mechanism for disseminating the results of its research and development activities. These results are published by NASA in the NASA STI Report Series, which includes the following report types:

- **TECHNICAL PUBLICATION.** Reports of completed research or a major significant phase of research that present the results of NASA programs and include extensive data or theoretical analysis. Includes compilations of significant scientific and technical data and information deemed to be of continuing reference value. NASA's counterpart of peer-reviewed formal professional papers but has less stringent limitations on manuscript length and extent of graphic presentations.

- **TECHNICAL MEMORANDUM.** Scientific and technical findings that are preliminary or of specialized interest, e.g., quick release reports, working papers, and bibliographies that contain minimal annotation. Does not contain extensive analysis.

- **CONTRACTOR REPORT.** Scientific and technical findings by NASA-sponsored contractors and grantees.

- **CONFERENCE PUBLICATION.** Collected papers from scientific and technical conferences, symposia, seminars, or other meetings sponsored or cosponsored by NASA.

- **SPECIAL PUBLICATION.** Scientific, technical, or historical information from NASA programs, projects, and missions, often concerned with subjects having substantial public interest.

- **TECHNICAL TRANSLATION.** English-language translations of foreign scientific and technical material pertinent to NASA's mission.

Specialized services that complement the STI Program Office's diverse offerings include creating custom thesauri, building customized data bases, organizing and publishing research results . . . even providing videos.

For more information about the NASA STI Program Office, see the following:

Institute for Computational Mechanics in Propulsion, University of Toledo, Toledo, OH 43606

Inviscid nonlinear surface boundary conditions are currently limited to 3rd order accuracy in time for non-moving surfaces and actually reduce to 1st order in time when the surfaces move. For steady-state calculations it may be possible to achieve higher accuracy in space, but high accuracy in time is required for efficient simulation of multiscale unsteady phenomena. A surprisingly simple technique is shown here that can be used to correct the normal pressure derivatives of the flow at a surface on a Cartesian grid so that arbitrarily high order time accuracy is achieved in idealized cases. This work demonstrates that nonlinear high order time accuracy at a solid surface is possible and desirable, but it also shows that the current practice of only correcting the pressure is inadequate.

I. Introduction

High order accuracy is required for efficient aeroacoustic simulations.1–3 Recently, it has been demonstrated4,5 that there is an optimal range of design accuracies in which the best efficiency and solution accuracy is obtained. The optimal value depends upon the length of the simulation and the level of accuracy required. For example, nonlinear inviscid aeroacoustics simulations with 6th order accuracy in space and time is optimal for propagating a wave five wavelengths with absolute error less than 10−6. Unfortunately, this is not typically achieved in practice because of the solid boundary conditions6 which may have high order spatial accuracy, but rarely exceed 2nd order time accuracy. This severely limits the efficiency of time marching methods.

This paper demonstrates why most surface boundary approaches are typically only 1st order accurate in time and it presents a surprisingly simple procedure for correcting the normal pressure derivatives to achieve any order of time accuracy in special cases. The basic idea follows the work of Tam7,8 in which walls are modeled by pressure corrections; and follows the work of Hixon9 in which the pressure corrections are treated separately from flow variables to greatly simplify their nonlinear implementation; and finally, those contributions are combined with Goodrich's boundary treatment10 to produce arbitrary time accuracy at a surface.

The usefulness of these ideas are currently limited to cases in which the pressure corrections are much larger than the density and velocity corrections. Nonetheless, the procedures shown here demonstrate the feasibility and efficiency of increasing the time accuracy at surfaces.

II. Problem Description

The following form of the two-dimensional nonlinear Euler equations are used:

\[
\begin{align*}
\frac{\partial p}{\partial t} + u \frac{\partial p}{\partial x} + v \frac{\partial p}{\partial y} + p \left( \frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} \right) &= Q_1 \\
\frac{\partial u}{\partial t} + u \frac{\partial u}{\partial x} + v \frac{\partial u}{\partial y} + \gamma p \left( \frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} \right) &= Q_2 \\
\frac{\partial (pu)}{\partial t} + \frac{\partial (pu^2 + p)}{\partial x} + \frac{\partial (puv)}{\partial y} &= Q_3 \\
\frac{\partial (pv)}{\partial t} + \frac{\partial (puv)}{\partial x} + \frac{\partial (pv^2 + p)}{\partial y} &= Q_4
\end{align*}
\]

At the solid boundary we also have the following infinite set of boundary conditions:10

\[
\frac{\partial^n (\hat{V} \cdot \hat{n})}{\partial t^n} = \frac{\partial^n Q_5}{\partial t^n} \gamma \alpha : (\alpha \geq 0)
\]

Ordinarily, the source terms \(Q_1, Q_2, Q_3, Q_4, Q_5\) are zero. But, for testing purposes, these terms will be modified so that the following analytical solution is defined:5

\[
\begin{align*}
\rho(x, y, t) &= a_1 \cos(k_x \pi x) \cos(k_y \pi y) \cos(k_z \pi t) + c_1 \\
u(x, y, t) &= a_2 \cos(k_x \pi x) \cos(k_y \pi y) \cos(k_z \pi t) + c_2 \\
v(x, y, t) &= a_3 \cos(k_x \pi x) \cos(k_y \pi y) \cos(k_z \pi t) + c_3 \\
p(x, y, t) &= a_4 \cos(k_x \pi x) \cos(k_y \pi y) \cos(k_z \pi t) + c_4
\end{align*}
\]
Due to the large number of derivatives used in what follows, the following shorthand notation will be used:

\[
\frac{\partial \chi_s}{\partial t} = \frac{\partial^3 f(x,y,t)}{\partial x^2 y^2 t^2} \tag{10}
\]

where \( \chi_s \) when used, will indicate: updated (U), new (N), old (O), or correction (C).

III. Maintaining High Accuracy at Boundary

This work uses high accuracy Hermitian Modified Expansion Solution Approximation (MESA) methods because high time accuracy at a surface requires correcting the spatial cross derivatives of the flow variables, many of which the MESA scheme explicitly includes on the grid. Any method could be used as long as the effect of cross derivative corrections are consistently applied. In Fig. 1, the absolute error of the numerical wavenumber for the derivative of a harmonic function, \( f(x) = \exp(ikx) \), is plotted by points per wavelength (PPW) as done in Ref.\(^{11}\) The extraordinary resolution of the two-point MESA schemes allows one to use fewer grid points and larger time steps, resulting in significant computational efficiency for problems requiring high physical accuracy as shown in Fig. 1.\(^{5,15}\) However, maintaining high accuracy at surfaces,\(^{12}\) particularly when waves are being scattered,\(^{13}\) is required to maintain this high efficiency.

Unfortunately, most inviscid surface boundary conditions are at most 2\(^{nd}\) order accurate in time since only the following conditions:

\[
\frac{\partial^\alpha(\vec{V} \cdot \hat{n})}{\partial t^\alpha} = 0 \forall \alpha : (\alpha = 0, 1) \tag{11}
\]

are used when in fact Eq. (5) is true for any \( \alpha \).

As an example, the numerical time advancement of the pressure on a surface expressed as a Taylor series is:

\[
p(x,y,t + \Delta t) = C_{0,0,0}^P + C_{0,0,1}^P \Delta t + C_{0,0,2}^P \frac{\Delta t^2}{2} + \ldots \tag{12}
\]

And from the governing equations Eqs. (1, 2, 3, 4) we can convert the series’ time derivatives into space derivatives. For example:

\[
-C_{0,0,1}^P = C_{0,0,0}^0 C_{1,0,0}^P + C_{0,0,0}^n C_{0,1,0}^P + \gamma C_{0,0,0}^P (C_{1,0,0}^u + C_{0,1,0}^n) \tag{13}
\]
vert the time derivatives to space derivatives again and
constraint on these 1st order spatial derivatives by con-
accuracy we must have the correct first order spatial
tial derivatives are correct at the surface.
be satisfied if the initial flow conditions and their spa-
order time accuracy. And in general, one must enforce
2 will provide a constraint on the first and second or-
and velocity derivatives that for \( \alpha = 1 \) provides a
constraint on these 1st order spatial derivatives by con-
verting the time derivatives to space derivatives again
using Eqs. (31, 31):

\[
-C_{0,2}^p = C_{1,0,0}^p C_{0,0,0}^p C_{0,1,0}^p C_{1,0,0}^p C_{0,0,0}^p C_{0,1,0}^p + C_{1,1,0}^p C_{0,0,0}^p C_{0,0,0}^p C_{0,1,0}^p C_{1,1,0}^p C_{0,0,0}^p + C_{2,0,0}^p C_{0,0,0}^p C_{0,0,0}^p C_{0,1,0}^p C_{2,0,0}^p C_{0,0,0}^p + C_{0,0,0}^p C_{1,1,0}^p C_{0,0,0}^p C_{0,1,0}^p C_{0,0,0}^p C_{1,1,0}^p + C_{0,0,0}^p C_{2,0,0}^p C_{0,0,0}^p C_{0,1,0}^p C_{2,0,0}^p C_{0,0,0}^p + C_{0,0,0}^p C_{0,0,0}^p C_{1,1,0}^p C_{0,0,0}^p C_{0,1,0}^p C_{0,0,0}^p
\]

\[\sum_{k=1}^{1} \left( \sum_{i=0}^{k-1} \frac{\partial^{k-i} \rho}{\partial t^{k-i}} \right) \left( n_{x} \frac{\partial u}{\partial t} + n_{y} \frac{\partial v}{\partial t} \right) (\Delta t)^{k} = 0 \]

(16)

At the new time step, the boundary condition, Eq. (5), for \( \alpha > 0 \) will in general not be true. For example, we know that after time advancing the primitive variables that for \( \alpha = 1 \):

\[
n_{x} \rho(x, y, t + \Delta t)u(x, y, t + \Delta t) + n_{y} \rho(x, y, t + \Delta t)v(x, y, t + \Delta t) = 0
\]

\[
n_{x} \rho(x, y, t)u(x, y, t) + n_{y} \rho(x, y, t)v(x, y, t) + \frac{O(\Delta t)}{k!} \left( n_{x} \frac{\partial^{k} \rho}{\partial t^{k}} + n_{y} \frac{\partial^{k} \rho}{\partial t^{k}} \right) (\Delta t)^{k} = 0
\]

(17)

Clearly it is necessary to correct the spatial derivatives at each time step to maintain time accuracy at the boundary. In this work however, only the spatial derivatives of the pressure are corrected because this approach was successful for the 1st order corrections used by Tam\(^{7}\) and Hixon.\(^{9}\) This approach reduces the seemingly intractible complexity of very high order nonlinear boundary conditions to a few lines of code. The downside to this approach is entropy and vorticity waves may be excited as no mechanism for properly correcting the density and velocity derivatives is provided here. For example, the one-dimensional characteristic form (entropy and two acoustic waves) of the Euler equations is:

\[
\frac{\partial u}{\partial t} + \frac{\partial p}{\partial x} = 0 \quad \text{for} \quad i = 1, 2, 3
\]

\[
d(v_1) = d(\rho) - \frac{d(p)}{c^2}
\]

\[
d(v_2) = d(u) + \frac{d(p)}{c^2}
\]

\[
d(v_3) = d(u) - \frac{d(p)}{c^2}
\]

(18)

where \( c \) is the speed of sound, \( s \) is the entropy, \( d(v_1) \) is the \( i \)th characteristic variable differential which is integrable for isentropic flows, and \( \lambda_i \) is the speed of the characteristic wave.

The time derivative of the Euler equations provides a new set of characteristics with the same velocities
but include higher order space derivatives:

\[
\frac{\partial}{\partial t} \left( \frac{\partial \psi}{\partial x} \right) + \lambda_1 \frac{\partial}{\partial x} \left( \psi \frac{\partial u_x}{\partial x} \right) + \frac{\partial}{\partial x} \left( \frac{\partial \psi}{\partial x} \right) = \lambda_1 \frac{\partial}{\partial x} \left( \frac{\partial \psi}{\partial x} \right) = 0, \quad i = 1, 2, 3
\]

\[
d(v_1) = d \left( -u(\rho_x + \frac{\xi}{c}) \right)
\]

\[
d(v_2) = d \left( -u(c + \frac{\xi}{c}) \left( u_x + \frac{\xi}{c} \right) \right)
\]

\[
d(v_3) = d \left( -u(c + \frac{\xi}{c}) \left( u_x - \frac{\xi}{c} \right) \right)
\]

where \( c \) is the speed of sound. In this analysis, the lower order terms are source terms and are assumed known (using the procedure provided later).

Differentiating once more in time provides a new set of characteristics with the same velocity as before:

\[
d(v_1) = d \left( u(\rho_x - \frac{\xi}{c}) - u(\rho_x + \frac{\xi}{c}) \right)
\]

\[
d(v_2) = d \left( (u + c)(u_x + \frac{\xi}{c}) + (u + c)(u_x - \frac{\xi}{c}) \right)
\]

\[
d(v_3) = d \left( (u - c)(u_x - \frac{\xi}{c}) + (u - c)(u_x + \frac{\xi}{c}) \right)
\]

In Eq. (18) the entropy characteristic, \( d(v_1) \) does not depend on velocity, but the new differentiated characteristic does depend upon velocity in Eq. (19). And, in Eq. (20) the new entropy characteristic depends on all flow variable first derivatives. By only correcting the pressure derivatives, the Euler system is under-specified because the velocity and density derivatives are incorrect at the surface. Ideally, all the flow variable derivatives would be corrected so that \( d(v_1) \) and the outgoing acoustic characteristic are not changed. This issue is beyond the scope of this paper since it is currently standard practice to only correct the pressure terms and since physically correct solutions have been achieved with it (probably because the required corrections in the other terms were small compared to the pressure). This will become more important as higher order time accuracy is required and the procedure shown next could be extended for such cases.

### IV. Surface Pressure Correction Algorithm

The basic idea\(^7\) is to modify the normal pressure derivatives on a boundary to satisfy the governing equations and boundary conditions. One-sided derivatives at a surface will generally be incorrect since they do not account for the walls presence, thus they need to be corrected. And, contrary to the assertion of only one physical boundary condition being available for high order finite-difference schemes, we make use of the infinite additional conditions\(^8\) in Eq. (5).

For a wall with normal vector, \( \hat{n} = (n_x, n_y) \), tangential vector, \( \tau = (\tau_x, \tau_y) \), and a numerical method with order \( O \) accuracy, the pressure derivatives:

\[
\frac{\partial^{a+b} p}{\partial x^a \partial y^b} \forall (a, b) : (1 \leq a + b \leq O) \quad (21)
\]

will be modified such that the boundary condition, Eq. (5), is satisfied while simultaneously insuring the tangential derivatives of the pressure:

\[
\frac{\partial^a p}{\partial x^a} + \frac{\partial^b p}{\partial y^b} \forall (a, b) : (1 \leq a + b \leq O) \quad (22)
\]

do not change on an inviscid wall.

We can represent the new pressure, \( p_N \), as the sum of the old, \( p_O \), and correction, \( p_C \), pressures:

\[
\frac{\partial^{a+b} p}{\partial x^a \partial y^b} \bigg|_N = \left( \frac{\partial^{a+b} p}{\partial x^a \partial y^b} \right)_O + \left( \frac{\partial^{a+b} p}{\partial x^a \partial y^b} \right)_C \quad (23)
\]

where

\[
C_{a,b,o} = \sum_{j=0}^\alpha A_j (-1)^j M_j
\]

\[
M_i = \sum_{b=0}^{\alpha-1} (-1)^{a+b+i} \left( \frac{\alpha(a-1)}{2} \right) n_x^a n_y^b \quad (24)
\]

\[
A_j = -n_x \left( T_{\alpha,j-1,i} C_{\alpha,j-1,0} + T_{\alpha,j-1,i} C_{\alpha,i-1,j} \right)
\]

\[
T_{\alpha,j,i} = (-1)^{-\alpha+i} \sum_{m=0}^{i-1} \sum_{\lambda=0}^{\alpha+i} \left[ H_{m,i,\alpha,\beta,\gamma} \right] = (-1)^{-\alpha+i} \sum_{m=0}^{i-1} \sum_{\lambda=0}^{\alpha+i} \left[ H_{m,\alpha,\beta,\gamma} \right] \quad (25)
\]

\[
H_{m,i,\alpha,\beta,\gamma} = \frac{\alpha-1)(m+i)!}{(\alpha - \beta - 2i - \gamma - 1)!2^{i+m}i!m!}
\]

\[
U_{i,\alpha,\beta,\gamma} = \frac{1}{(\alpha-1)(m+i)!}
\]

The updated term, \( U_{i,\alpha,\beta,\gamma} \) in Eq. (24), refers to the value of \( C_{\alpha,0,0} \) after the lower order pressure derivatives have been corrected. For example, we first correct the 1st \( (\alpha = 1) \) order pressure derivatives, \( (p_x, p_y) \), using Eq. (24). Next, the higher order time derivatives, \( U_{i,\alpha,\beta,\gamma} \) are calculated, but using the new values of \( p_x \) and \( p_y \). These "updated" time derivatives are then used to calculate new 2nd \( (\alpha = 2) \) order pressure derivatives, \( p_{xx}, p_{yy}, p_{xy} \), with Eq. (24).

This process is repeated until the desired accuracy is achieved. A complete derivation of Eq. (24) may be found in the appendix.
V. Results

The adequacy of correcting only the pressure derivatives to achieve high time accuracy was tested by scattering the initial Gaussian pulse:

\[ p(x, y, 0) = 0.001 \exp \left( -\frac{\ln 2[(x - 1)^2 + y^2]}{.04} \right) \]  

(28)

with four grid points per unit interval from a flat plate at progressively higher order accuracy. The initial uniform flow conditions were \( \rho = 1.4, p = 1.0, u = 0, \) and \( v = 0 \).

In Fig. 2, pressure contours of the reflected pulse are shown for the 3rd order conditions. The solution is stable, but the reflected pressure is slightly amplified. The pressure is over-corrected (amplified) because the effects of the other uncorrected variables must be accounted for to maintain the no-flow boundary conditions, Eq. (5). As the accuracy increases, the number and effect of uncorrected variables increases resulting in an over-correction of the pressure that leads to numerical instability, unless some damping mechanism is added.

In Fig. 3, the reflected pulse using the 3rd order conditions are compared with the current practice of correcting only the first derivatives, \( p_x \) and \( p_y \) using 3rd and 1st order design time accuracy at the surface (though both achieve only 1st order time accuracy as mentioned). The 3rd order time accuracy cases in Figs. 3a and 3b, showed little difference here suggesting the higher order corrections are small, but the 1st order time advance in Fig. 3c generated spurious waves and was unstable.

The 5th order example in Fig. 4 shows more clearly the importance of correcting the higher derivatives. Despite only correcting the pressure, the reflected pulse is qualitatively superior to correcting only the first order pressure derivatives. The simulation becomes unstable however on the surface after the pulse has reflected from it at time \( t = 0.8 \). Higher order conditions result in larger over-corrections of the pressure, as expected. Note that the MESA scheme explicitly uses the 2nd order spatial derivatives and the effects of high order boundary corrections are directly observable. Other methods may perform differently for the cases shown in Fig. 4b and 4c., though their results remain nonphysical.

As a test of the procedures on curved surfaces with a Cartesian grid, the same Gaussian pulse was scattered from a sphere of radius, \( r = .25 \), with a grid density of 128 points per unit interval. In Fig. 5, a 3rd order solution is shown. The curvature results in greater changes in the velocity and the pressure corrections must compensate for that, resulting in a dissipated, but clearly reflected pulse and was numerically stable. The higher order conditions (> 4) were unstable without adding artificial dissipation for the circle case.

As a more realistic example, observe the entropy production shown for the 2D stator blade passage in Fig. 6 in which the height of the grid indicates magnitude of the entropy. Only the 1st order pressure derivatives are corrected and for this inviscid problem the solution should be flat, indicating no change in entropy. Here, the curvilinear form of the nonlinear Euler equations are solved using a 6th order compact scheme\(^{18}\) for spatial derivatives and a 4th order 5-6 Low Dispersion and Dissipation Runge-Kutta scheme for time marching.\(^{19}\) Notice the entropy production at the suction surface and convected downstream in the wake.

Overall, the advantages of correcting the high order spatial derivatives is clear, and as shown in Fig. 1, the efficiency of high accuracy is evident for demanding long-term low error tolerance simulations. But the current practice of correcting only the pressure is not physically correct despite the flow variables satisfying the governing equations and boundary conditions at the surface. The practice is still nonphysical (e.g., produces entropy and vorticity) because the characteristics are under-specified and therefore the other flow variables must be corrected as well.

VI. Conclusion

Most surface boundary methods in use today achieve only 1st order accuracy in time since only the no flow condition is imposed. Higher time accuracy requires enforcing the higher order time derivatives of the no flow condition. In the special case of stationary surfaces, the even ordered time derivatives of the no flow condition will be automatically satisfied if they were correctly specified at the start of the simulation.

The primary advantage of high time accuracy is better resolution and larger time steps at surfaces. Achieving high time accuracy requires correcting cross-derivatives of the flow at a surface. In principle, any numerical method could be used with the boundary procedure presented here. But a Hermitian MESA scheme was used because of its extraordinary resolution and potential for efficiency at a surface with high time accuracy. The exact performance advantages of high time accuracy will depend upon the physical accuracy required.

The design time accuracy was increased here by correcting only the pressure as is the currently accepted 1st order practice. Despite the apparently high complexity in deriving very high order pressure corrections, a simple process for doing this was found that requires only a few lines of code to implement. However, a characteristic analysis and numerical testing has revealed that it is important to correct the velocity and density spatial derivatives as well. Therefore, an important next step is to correct all flow derivatives to avoid underspecifying the hyperbolic Euler system and to extend this analysis to curvilinear coordinates.

VII. Appendix: Derivation of Pressure Correction

The pressure correction procedure shown in section IV was derived by assuming only the pressure’s spatial derivatives required adjustment to account for the presence of the wall. After the corrections are applied, the flow variables and their spatial derivatives must satisfy the nonlinear Euler equations and the boundary condition at the surface. In addition, the flow’s spatial derivatives must satisfy the time derivatives of these equations to achieve high accuracy in time.

Starting with the following boundary condition, from Eq. (5), for any $\alpha$:

$$\frac{\partial \alpha(\vec{V}, \vec{n})}{\partial \alpha} = n_x \frac{\partial^2 u}{\partial \alpha^2} + n_y \frac{\partial^2 v}{\partial \alpha^2} = c_{Q_x}$$

(29)

we want to correct the pressure derivatives so that the following is satisfied:

$$n_x \left( \frac{\partial^2 u}{\partial \alpha^2} + \frac{\partial^2 v}{\partial \alpha^2} \right) = c_{Q_x}$$

(30)

The terms, $C_{\alpha,0,0}$ and $C_{\alpha,0,0}$, are the corrections to the time derivatives of the velocities resulting from the corrections to the spatial derivatives of the pressure. We need to determine how changes in the pressure derivatives will effect the velocity time derivatives so that Eq. (30) is satisfied up to some specified order $\alpha$.

This relationship can be found using the governing equations, Eqs. (1, 2, 3, 4) and the following alternate form of the momentum equations:$^{16}$

$$\frac{\partial u}{\partial \alpha} = -\left( \frac{u \partial u}{\partial x} + v \frac{\partial u}{\partial y} + \frac{1}{\rho} \frac{\partial p}{\partial x} \right)$$

$$\frac{\partial v}{\partial \alpha} = -\left( \frac{u \partial v}{\partial x} + v \frac{\partial v}{\partial y} + \frac{1}{\rho} \frac{\partial p}{\partial y} \right)$$

(31)

From this alternate momentum equation form we find the following relationship:

$$C_{\alpha,0,0} = -\left( C_{\alpha,0,0} C_{\alpha,0,0} + C_{\alpha,0,0} C_{\alpha,0,0} + \frac{1}{C_{\alpha,0,0}} C_{\alpha,0,0} \right)$$

$$C_{\alpha,0,0} = -\left( C_{\alpha,0,0} C_{\alpha,0,0} + C_{\alpha,0,0} C_{\alpha,0,0} + \frac{1}{C_{\alpha,0,0}} C_{\alpha,0,0} \right)$$

(32)

which shows how changes in pressure and velocity mixed space and time derivatives will affect the boundary condition equation.

The critical and most difficult next step in this derivation is expressing the right hand side of Eq. (31) in terms of the corrected pressure’s spatial derivatives. This was done by recursively differentiating all six governing equation forms with computer algebra until a pattern could be discerned. The following pattern was observed and inductively verified:

$$C_{\alpha,0,0} = \sum_{j=0}^{\alpha} C_{\alpha-j,j,0} T_{\alpha,1,j,u,v}$$

$$C_{\alpha,0,0} = \sum_{j=0}^{\alpha} C_{\alpha-j,j,0} T_{\alpha,1,j-1,u,v}$$

$$C_{\alpha,0,0} = \sum_{j=0}^{\alpha} C_{\alpha-j,j,0} T_{\alpha,1,j-1,u,v}$$

$$C_{\alpha,0,0} = \sum_{j=0}^{\alpha} C_{\alpha-j,j,0} T_{\alpha,1,j-2,u,v}$$

$$C_{\alpha,0,0} = \sum_{j=0}^{\alpha} C_{\alpha-j,j,0} T_{\alpha,1,j-2,u,v}$$

(33)

where $T_{\alpha,j,j,\alpha}$ is defined in Eq. (27).

For each value of $\alpha$, we can now correct the following pressure derivatives:

$$C_{\alpha-j,j,0} \forall j = 0, 1, \ldots, \alpha$$

(34)
Fig. 6 Entropy Produced on Surface of Stator Blade On Curvilinear Grid
by substituting Eq. (33) into Eq. (32) and solving boundary condition Eq. (30):
\[
\sum_{j=0}^{\alpha} C_{\alpha-j,0}^{\alpha} A_j = C_{0,0,0}^{\alpha} n_x C_{0,0,0,0}^{\alpha} - n_y C_{0,0,0,0,0}^{\alpha} \tag{35}
\]
with \(A_j\) defined in Eq. (26).

In addition, since we do not want corrections of the pressure derivative to effect the tangential derivatives, we impose, for each \(\alpha\) the following \(\alpha\) conditions:
\[
\left(\frac{\partial^\alpha p}{\partial x^\alpha \partial \eta^j}\right)_{\text{correction}} = 0 \quad \forall \quad j = 0, 1, \ldots, \alpha - 1
\]
which can be written as a condition on only the Cartesian \(x\) and \(y\) pressure derivatives as:
\[
\left(\frac{\partial^\alpha p}{\partial x^\alpha \partial \eta^j}\right)_{\text{correction}} = \left(\frac{\partial \eta_x}{\partial \eta^j} \delta_{\alpha-j} \frac{\partial \eta_y}{\partial \eta^j} \right) p = \sum_{\alpha=0}^{\alpha} C_{\alpha-a,a,0}^{\alpha} B_{a,j} = 0
\]
with
\[
B_{a,j} = \sum_{b=0}^{j} \left( \begin{array}{c}
\alpha - j \\
\alpha - b
\end{array} \right) \left( \begin{array}{c}
1 \\\nb
\end{array} \right) \left(\frac{\partial \eta_x}{\partial \eta^j} \right)^{(2b-a)} \left(\frac{\partial \eta_y}{\partial \eta^j} \right)^{(\alpha-j+2b-a)}
\]
which is zero, except the first term, we can efficiently solve this system with Cramer’s rule for the \(i^{th}\) element of vector \(C\):
\[
C_i = \frac{\det(F)}{\det(E)} \tag{39}
\]
where matrix \(F\) equals matrix \(E\) with column number \(i\) replace by vector \(D\).

The determinant of a matrix may be solved using cofactor expansion along a column. So we can take advantage of all the zeros in \(F\) by expanding along column \(i\) to efficiently evaluate the determinant of the matrix:
\[
\det(F) = \left( C_{0,0,0}^{\alpha} n_x C_{0,0,0,0}^{\alpha} - n_y C_{0,0,0,0,0}^{\alpha} \right) (-1)^i M_i \tag{40}
\]
where \(M_i\) is the minor of the element in the first row and \(i^{th}\) column of matrix \(F\).

Similarly we can evaluate the determinant of matrix \(E\) by cofactor expansion along the top row:
\[
\det(E) = \sum_{j=0}^{\alpha} A_j (-1)^j M_j
\]
\[
= (-1)^\alpha (n_x^2 + n_y^2)^{(\alpha-1)\frac{1}{2}} \left( \sum_{i=0}^{\alpha} n_x^i n_y^i \right) \tag{41}
\]
with \(A_j\) is defined in Eq. (26). The expression for \(M_j\), from Eq. (25), was derived by observation with the help of computer algebra and verified inductively.

With \(M_j\) known, we can quickly apply Cramer’s rule to solve Eq. (39) for the unknown pressure correction vector \(C\) in Eq. (38). This simple procedure is repeated for \(\alpha = 1, 2, \ldots, O\) until all higher order pressure spatial derivatives are corrected.

Inviscid nonlinear surface boundary conditions are currently limited to third order accuracy in time for non-moving surfaces and actually reduce to first order in time when the surfaces move. For steady-state calculations it may be possible to achieve higher accuracy in space, but high accuracy in time is required for efficient simulation of multiscale unsteady phenomena. A surprisingly simple technique is shown here that can be used to correct the normal pressure derivatives of the flow at a surface on a Cartesian grid so that arbitrarily high order time accuracy is achieved in idealized cases. This work demonstrates that nonlinear high order time accuracy at a solid surface is possible and desirable, but it also shows that the current practice of only correcting the pressure is inadequate.
