Technologies for Turbofan Noise Reduction

Dennis Huff
NASA Glenn Research Center

ABSTRACT

An overview presentation of NASA’s engine noise research since 1992 is given for subsonic commercial aircraft applications. Highlights are included from the Advanced Subsonic Technology (AST) Noise Reduction Program and the Quiet Aircraft Technology (QAT) project with emphasis on engine source noise reduction. Noise reduction goals for 10 EPNd lost by 2007 and 20 EPNd lost by 2022 are reviewed. Fan and jet noise technologies are highlighted from the AST program including higher bypass ratio propulsion, scarf inlets, forward-swept fans, swept/leaned stators, chevron nozzles, noise prediction methods, and active noise control for fans. Source diagnostic tests for fans and jets that have been completed over the past few years are presented showing how new flow measurement methods such as Particle Image Velocimetry (PIV) have played a key role in understanding turbulence, the noise generation process, and how to improve noise prediction methods. Tests focused on source decomposition have helped identify which engine components need further noise reduction. The role of Computational AeroAcoustics (CAA) for fan noise prediction is presented. Advanced noise reduction methods such as Herschel-Quincke tubes and trailing edge blowing for fan noise that are currently being pursued in the QAT program are also presented. Highlights are shown from engine validation and flight demonstrations that were done in the late 1990’s with Pratt & Whitney on their PW4098 engine and Honeywell on their TFE-731-60 engine. Finally, future propulsion configurations currently being studied that show promise towards meeting NASA’s long term goal of 20 dB noise reduction are shown including a Dual Fan Engine concept on a Blended Wing Body aircraft.

New Technology Enables Aircraft To Meet Future Requirements
Aircraft Fleet Noise Reduction Needed For 55 LDN Noise Contours Within Airport Boundaries

According to a document from the U.S. Environmental Protection Agency (EPA) published in the 1970’s, 55 LDN is the outdoor noise exposure level "requisite to protect the public health and welfare with an adequate margin of safety". The phrase "health and welfare" is defined as "complete physical, mental and social well-being and not merely the absence of disease and infirmity".

Data

*Data includes a recently discovered 3 dB correction*
Computational Aeroacoustics for Fan Noise Prediction (Time-Domain)

**Methodology**

- Time-Accurate, Non-linear & Inviscid Simulation
- Validated in 2D. Extension to 3D is Underway

Harmonic content of unsteady pressure (only 9 passages shown)
Fan Broadband Noise Prediction

Methodology

- Fan Wake Turbulence Description: Steady RANS
- OGV Acoustic Response: Strip-wise lift response (2D cascade)
  Classical duct acoustics (3D)

Inlet and Exhaust PWL at Approach Condition (Stator Contribution Only)
Data includes both coherent and broadband, theory only includes broadband
