Since its founding, NASA has been dedicated to the advancement of aeronautics and space science. The NASA Scientific and Technical Information (STI) Program Office plays a key part in helping NASA maintain this important role.

The NASA STI Program Office is operated by Langley Research Center, the lead center for NASA’s scientific and technical information. The NASA STI Program Office provides access to the NASA STI Database, the largest collection of aeronautical and space science STI in the world. The Program Office is also NASA’s institutional mechanism for disseminating the results of its research and development activities. These results are published by NASA in the NASA STI Report Series, which includes the following report types:

- TECHNICAL PUBLICATION. Reports of completed research or a major significant phase of research that present the results of NASA programs and include extensive data or theoretical analysis. Includes compilations of significant scientific and technical data and information deemed to be of continuing reference value. NASA’s counterpart of peer-reviewed formal professional papers but has less stringent limitations on manuscript length and extent of graphic presentations.

- TECHNICAL MEMORANDUM. Scientific and technical findings that are preliminary or of specialized interest, e.g., quick release reports, working papers, and bibliographies that contain minimal annotation. Does not contain extensive analysis.

- CONTRACTOR REPORT. Scientific and technical findings by NASA-sponsored contractors and grantees.

- CONFERENCE PUBLICATION. Collected papers from scientific and technical conferences, symposia, seminars, or other meetings sponsored or cosponsored by NASA.

- SPECIAL PUBLICATION. Scientific, technical, or historical information from NASA programs, projects, and mission, often concerned with subjects having substantial public interest.

- TECHNICAL TRANSLATION. English-language translations of foreign scientific and technical material pertinent to NASA’s mission.

Specialized services that complement the STI Program Office’s diverse offerings include creating custom thesauri, building customized databases, organizing and publishing research results . . . even providing videos.

For more information about the NASA STI Program Office, see the following:

Acknowledgments

The Apollo Medical Operations Project was a team effort. Members of this team included the core Summit group at Wyle Labs: Kae Parker, Phyllis McCulley, Mary McFarther, Luisa Rivera, Christopher Stokes, Marilyn Sylvester, Karen Mathis and Sandy Ballesteros. The facility hosting the Summit, Space Center Houston, provided excellent accommodations and service led by Sheri Armstrong. The JSC Center Director, Michael Coats, provided opening remarks to the group and set the tone for the meeting. A tremendous thank you is offered to Dr. Joe Kerwin who provided insight and encouragement throughout the development process and for the face-to-face meeting. Of course, thank you to all the NASA-JSC flight surgeons and astronaut physicians: Ellen Baker, Lee Morin, Scott Parazynski, Michael Barratt, Thomas Marshburn, Bob Satcher, David Wolfe and Anna Fischer offered their time in preparing for the meeting which could not have happened without them. Other individuals contributed to the writing of the manuscript and deserve heartfelt thanks: Barabara Tomaro, Donna Baumer, Jennifer Fogarty, Nancy House and Malinda Moller. Lastly, the future generation of lunar explorers will benefit greatly from the servant spirit offered during the few days in June 2006 by the Apollo astronauts and flight surgeons. Their effort will improve the new vehicles and protect crew health and performance for years to come.

Abstract

**Introduction.** Medical requirements for the future Crew Exploration Vehicle (CEV), Lunar Surface Access Module (LSAM), advanced Extravehicular Activity (EVA) suits and Lunar habitat are currently being developed. Crews returning to the lunar surface will construct the lunar habitat and conduct scientific research. Inherent in aggressive surface activities is the potential risk of injury to crewmembers. Physiological responses to and the operational environment of short forays during the Apollo lunar missions were studied and documented. Little is known about the operational environment in which crews will live and work and the hardware that will be used for long-duration lunar surface operations. Additional information is needed regarding productivity and the events that affect crew function, such as a compressed timeline. The Space Medicine Division at the NASA Johnson Space Center (JSC) requested a study in December 2005 to identify Apollo mission issues relevant to medical operations that had impact to crew health and/or performance. The operationally oriented goals of this project were to develop or modify medical requirements for new exploration vehicles and habitats, create a centralized database for future access, and share relevant Apollo information with the multiple entities at NASA and abroad participating in the exploration effort.

**Methods.** A review of medical operations during Apollo missions 7 through 17 was conducted. Ten categories of hardware, systems, or crew factors were identified during preliminary data review generating 625 data records, which were captured in an Access database. The preliminary review resulted in 285 questions which were posed to surviving Apollo crewmembers using mail, face-to-face meetings, phone communications, or online interactions. Crewmember responses to these questions formed the basis for recommendations to items in each of the categories.

**Results.** Fourteen of 22 surviving Apollo astronauts (64%) participated in the project. Approximately 236 pages of responses to the questions were generated based on the Apollo experiences, with 107 recommendations garnered for future vehicles, habitats, EVA suits, and lunar surface operations.

**Discussion.** The Apollo medical operations recommendations are being incorporated into the exploration mission architecture at various levels: 21 recommendations either validated, revised or created new requirements, 4 are currently in practice, 34 are being evaluated, and 54 are being considered. A centralized database has been developed, and the recommendations have been presented to the different organizations involved with building the new vehicles, habitats, suits, or systems that may impact crew health and performance.

**Conclusions.** The Apollo crewmembers’ input has proved to be an invaluable resource to a multitude of departments beyond space medicine. We will continue soliciting input from this group as we evolve and refine requirements for future exploration missions.
1.0 INTRODUCTION

The Apollo program, which began in January of 1966, was comprised of 18 missions: 12 crewed missions (including the Apollo 204 mission with Virgil “Gus” Grissom, Ed White, and Roger Chaffee) and six crewless missions which tested the capabilities of the Saturn rocket components. The Apollo 7 mission heralded the first successful crewed mission, and in July of 1969, Apollo 11 fulfilled John F. Kennedy’s mandate to send a man to the moon and return him safely home. Twenty-six men flew Apollo missions, including four repeat flyers. Of the manned missions, six flights conducted between July 1969 and December 1972 successfully landed 12 humans on the lunar surface and returned them to the Earth.

In January 2004, President George W. Bush committed the United States to the further exploration of space. This new vision for space exploration has the benefit of the cumulative knowledge and experience gained from the Apollo program. The exploration effort will require the development of new vehicles to transport crews from Earth to the lunar surface and for transportation while on the moon. In addition, crew will need (EVA) suits and extended duration habitation elements for the lunar surface operations. The Crew Exploration Vehicle (CEV) and Lunar Surface Access Module (LSAM) though slightly larger, will bear many similarities to the Apollo Command Module (CM) and Lunar Module (LM). The EVA suits may serve the dual function of a launch and entry suit as well as the lunar surface suit. Lunar habitation is a new frontier, enabling humans to live on the moon for extended periods in order to conduct science experiments and use the lunar environment for in-situ resource utilization.

During previous studies, Apollo astronauts provided input into the engineering and mechanical aspects of EVA suit system designs. However, no study has specifically addressed the impact of the Apollo vehicles, hardware, and systems on crew health or performance throughout all mission phases, including lunar surface operations and the influence of that impact on the new exploration vehicles and mission architectures.

To identify Apollo mission issues that had impact to crew health and/or performance and were relevant to medical operations, the Space Medicine Division requested a study in December of 2005. The goals of this project were to develop or modify medical requirements for new vehicles and habitats, create a centralized medical operations database for future access, and provide this knowledge to the multiple directorates at NASA-JSC participating in the exploration effort. Secondary objectives included using this information to validate current requirements and refresh knowledge regarding lunar operations in an effort to reduce programmatic risks and risks to crew health, productivity, and safety. The Space Medicine Division study and this paper are not intended to be a review of information contained in previous publications, such as Biomedical Results of Apollo.

Due to the multidisciplinary operational focus of this study, the target audience is diverse. This audience includes flight surgeons, engineers, and scientists developing the medical requirements for exploration vehicles, habitats, and suits, the mission planners developing crew timelines, and experts supporting behavioral health and performance.
Various aspects of this report will be of interest to a broader readership outside the medical operations community. Therefore, the report is written in a medically non-attributable format accessible to anyone with an interest in the Apollo program.

The Apollo Medical Operations Project was headed by Rick Scheuring, DO, MS, UTMB/Wyle Labs flight surgeon, James D. Polk, DO, MS, Manager of Medical Operations at JSC and Josef Schmid, MD, also with Medical Operations at JSC. The team included other flight surgeons from the Medical Operations office at JSC and University of Texas Medical Branch, Galveston, as well as project scientists and engineers within the Space Life Sciences Directorate (SLSD) and the Mission Operations Directorate (MOD) at JSC. Participation of the Apollo astronauts was solicited through the Space Medicine Division. The team would like to acknowledge the enormity of the task and express an appreciation to the Apollo crews for discussing their missions which occurred at a time when most of the team members were still children.

2.0 METHODS

This section addresses the spectrum of approaches taken to assimilate, categorize, and assess the data.

2.1 Background Research

Background research was undertaken by the Apollo Medical Operations Project team to maximize the benefits from the study. The approach taken consisted of the following:

- Identify specific medical-related problems, if any, in each area associated with the operational environment during all mission phases
- Define the impact on crew health and/or performance
- Identify problems that recurred or were fixed on subsequent missions
- Develop an integrated, comprehensive set of questions that could be used in a face-to-face meetings with the Apollo astronauts

The impetus to “do our homework” before meeting with the astronauts came from the Apollo crewmembers themselves. The crews voiced annoyance at discussing subjects or responding to questions that had previously been published. Therefore, it was incumbent upon the team to research areas and develop questions not previously documented.

Review of Apollo resources pertaining to Medical Operations and the sources of data included: Apollo medical mission debriefs (7-17); Apollo flight surgeon logs (7-17); Apollo biomedical engineer logs (7-17); Apollo mission commentaries (7-17); Apollo mission reports (11-17); Apollo lunar surface journals (11-17); preliminary science reports (11-17); the Apollo lecture series; Apollo videos; NASA technical
memorandums, related papers\textsuperscript{2,14,15,16,17,18}; and personal communications with the crewmembers through email, phone or direct contact. These materials were reviewed by the team to understand the Apollo astronauts’ experiences and the issues impacting their health and/or performance as previously reported. It is important to note that the medical debriefs and flight surgeon/biomedical engineer logs are considered medically confidential material and subject to the Medical Privacy Act of 1974. All other resources are available to the public. It is equally important to note that some issues identified in the debriefs were detailed in the crew logs, crew questionnaires, or air-to-ground communications but were unavailable. Every attempt was made to fill in the missing information from available resources for this study.

After reviewing historical data, the team identified eleven categories within the operational environment occurring during Apollo 7-17 that had impacts to crew health and/or performance. The data assembled into these categories formed the basis of the questions used to interview the Apollo astronauts. The categories included EVA mobility unit (EMU) and EVA suit issues; lunar surface operations; inflight illnesses; medical kit, medications, or bioinstrumentation; environmental (vehicle); radiation; exercise; food and nutrition; performance and human factors; crew schedule; launch, re-entry, and recovery; and flight surgeon-crew interactions. Certain well-documented areas relating to crew health or performance, such as lunar dust, were identified but not covered in detail during this study. Likewise, areas that affected the Apollo crews but were not relevant to the new vehicle design, such as the Apollo water chlorination system, were identified in the data collection but were not addressed during the face-to-face meetings.

2.2 Data Collection

The historical data collected was organized and compiled into an Access database (Appendix A). This database facilitated the search capabilities of the team in identifying areas that had health and/or performance impacts. The data was organized by mission, source of information, topic (category), medical/hardware issue, crewmember involved (if applicable), description of the problem, general comments about the issue, and resolution/reoccurrence. Questions related to the issue were generated from this body of data. The team used this method, to create 625 data records. An example of one record is provided in Figure 1. Note that any attributable medical information contained in Appendix A has been removed for the purpose of this paper and exists as a separate document.
2.3 Panel Questions

Questions were generated from the historical data search effort and from operational and research disciplines associated with each category (Appendix B). These questions were augmented with others solicited from discipline leads in each category. The categorized questions were reviewed by flight surgeons and current astronaut physicians at JSC for relevance and operational applicability to the exploration effort. This resulted in a final list of 285 questions used during the face-to-face meeting with the Apollo astronauts.

2.4 Face-to-Face Summit

The face-to-face summit with the Apollo astronauts was held in June of 2006 in Houston, Texas. Per the crewmembers’ request, Days 1 and 2 were closed sessions limited to Apollo crew, the current flight surgeon cadre and astronaut physicians. Day 3 was limited to invited guests and the Apollo flight surgeons. Of the original 29 Apollo astronauts, 22 survive today and were invited to participate in the face-to-face summit (Appendix E). Dr. Joseph Kerwin, who served as CAPCOM for Apollo 13 and astronaut physician on Skylab I, was a project team member and invited to participate as an astronaut. The invited guests for Day 3 submitted questions to the Apollo Medical
Operations Project team prior to the meeting to insure the appropriateness of the question and to facilitate interaction with the crewmembers during the session.

Prior to the panel question discussion on Days 1 and 2, the project team presented informational briefings to achieve the intended outcome of the meeting. The two-fold purpose of the meetings was to capture the experiences of the Apollo astronauts to validate findings from the historical data search and to project applicable aspects of Apollo operational experience to the exploration initiative. The project team presented the issues that faced the crews during their missions from the historical data research to increase their awareness of the current knowledge base. It also served to stimulate memories garnered three and a half decades ago. The presentation concluded with a discussion of the exploration architecture to familiarize the participants with the new strategies and mission plans.

The panel discussions were held with the astronauts and project team members meeting in one room. A professional transcriptionist recorded all comments from the astronauts and later organized the responses with the corresponding questions. The Day 3 session was conducted in a similar manner by the team and transcriptionist. This document was then reviewed by the project team for accuracy and clarification. Notes taken by the panel team during the question sessions were added to the document as necessary.

2.5 Post-Summit Review and Validation

The purpose of the post-summit phase was to compile the accumulated responses to the panel questions and then organize the responses into a comprehensive report (Appendix B). Apollo astronauts who participated in the face-to-face summit reviewed and validated the report. They also submitted additional input and points of clarification. After review by the project team, the updated version including recommendations was then submitted to all the Apollo astronauts providing an opportunity for an additional six crewmembers not attending the face-to-face meetings to participate. These responses can be found in Appendix G.

3.0 RESULTS

3.1 Data

Sixty-four percent (14 of 22) of the surviving Apollo astronauts participated in the project. The combined crewmember responses to the 285 questions generated from the background research resulted in 236 pages of data. A comprehensive review of all the responses from the astronaut sources revealed 107 recommendations that was subsequently broken down into 113 recommendations for easier data analysis (Appendix C). The input shown in Table 1 formed the basis of the Apollo Medical Operations Project recommendations. Note that the total number of astronauts participating includes
the eight attendees plus the responses to the post-summit report and questionnaire which included both attendees (4) and non-attendees (3).

4.0 OPERATIONAL AND RESEARCH RECOMMENDATIONS BY CATEGORY

4.1 EMU/EVA Suit

1. **Improve glove flexibility, dexterity, fit.** According to the Apollo lunar crews, the most fatiguing part of surface EVA tasks was repetitive gripping. Regarding the glove, one crewmember stated, “Efficiency was no more than 10% of the use of the hand.” The fingernails generally tended to be pulled back resulting in separation of the nail from the bed, or onycholysis. Additionally, the skin frequently was abraded from the top of the knuckles. This event took on operational and potentially mission significance as several lunar walkers stated that they would not be able to work in the glove beyond the two to three EVA’s they completed due to the swelling and pain over the bony prominences of the metacarpal phalangeal (MCP) and proximal interphalangeal (PIP) joints (knuckles), although had they been asked, it is probably that at least one more EVA would have been possible. It is also interesting to note that the lunar crews stated that they did not experience hand or forearm trauma in training, though muscle fatigue occurred. However, these training sessions typically lasted only two to three hours whereas the lunar EVA’s plus pressurized prep time were seven to nine hours in duration. [Note: Recent experience with ISS-related EVA’s suggests that better conditioning can solve most of the forearm fatigue problems; however, lack of dexterity and hand trauma remain as critical issues. (For perspective, you may wish to expand on the ISS experience as it relates to future lunar work.)] In terms of flexibility and fit, the glove should come as close to Earth-normal use of the hands as possible. Lowering the pressure [in the suit] was suggested, i.e., the less strength it takes to manipulate the glove, the less physically tasking to the hand and forearm musculature. This can also be accomplished by reducing the glove bulk and making the bladder thinner. Other glove recommendations included:

- Gloves should be custom designed for each crewmember and should incorporate mechanical closure for gripping
- Designers should consider a wrist seal and depressurized glove
- Robotic power-assisted glove should be used for repetitive tasks
- Special inner bladder surfaces should be developed and glove liners should be worn to prevent skin chaffing and abrasions

A consensus statement made by the Apollo astronauts who participated in the project on the EVA suit issue was that given a fixed budget for suit development and improvement, the funding for the new suit would be best spent in improving the glove. If money is left over for other components, then address those issues, but fix the glove first.

2. **Reduce the mass of the suit by a factor of two.** Once the glove issues have been addressed, reducing the suit mass would help. Availability of recharge of consumables during EVA should be strongly considered. Despite suit bulkiness, the astronauts cautioned that suit mass was an asset to some extent in the partial gravity environment. It provided an inertial point of reference that allowed them to adapt to 1/6 g. (But that point is always going to be there as long as some significant mass is present – i.e., body, suit,
Reducing the suit mass too much would remove the familiarity the crewmembers relied on and may predispose one to falls.

3. **Increase general mobility by a factor of four.** EVA suit mobility was more of an issue in terms of surface locomotion and energy expenditure. The crews often felt they were fighting the resistance in the suit (including in the glove as mentioned above). This was fatiguing, especially in the thighs. The astronauts pointed out that the lunar surface is more similar to an ocean than to a desert. The undulating surface posed a number of challenges, including ambulating against a suit that did not allow mobility at the hip. Normal human locomotion includes flexion at the hip and the Apollo A7LB had limited ability to bend the suit at the hip and to rotate within the suit. The crewmember had to bend forward from the knee joint, which demanded considerably more work load on the quadriceps muscles. Therefore, the mobility recommendations centered on adding hip mobility and improved knee flexibility. One comment summed this point well, “**Bending the knee was difficult in the suit. We need a better [more flexible] knee joint.**”

Reducing suit pressure to ~3.0 psia (sea-level oxygen partial pressure) with a pure oxygen system would accomplish this to some extent. However the crews understood the limitations with using this approach to improving suit mobility. Namely, the risk of decompression sickness would be increased and the margin of safety with a suit puncture would be decreased (This risk could be mitigated by an emergency regulation of oxygen flow to maintain 3.0 psia). It was also pointed out that lowering suit pressure may remove some of the suit extremity splinting effect and could predispose to limb injury, which was generally not a concern at the Apollo suit pressure of 3.75 psia.

4. **Lower suit Center of Gravity (CG).** Although this area has garnered considerable attention recently with new suit design, the crews felt it was not a main issue, compared to the glove issues or suit mobility. They reported adapting to the suit CG quickly on the lunar surface, which was described as “aft and slightly high.” A number of crewmembers stated “Don’t make moving the CG your primary priority. Move the CG only if it becomes convenient to do so while taking care of other issues like reducing the mass of the suit, fixing the glove, etc.”

5. **Develop a system that prevents helmet fogging during heavy exertion.** Although the lunar walkers did not experience fogging of their visor while on the moon and used an anti-fogging wipe to prevent it, its possible occurrence could be catastrophic. An example for potential adverse effects due to visor fogging was the Apollo 11 mission. Crewmembers remained in their suits during recovery operations for quarantine concerns. The visor fogged once the CM was opened to the humid, warm South Pacific air, completely obscuring their vision. One crewmember became very concerned during transfer from the CM to the rescue basket, as he was unable to clear the visor to see where he was going. Whether it was due to exterior fogging due to the cooler visor causing condensation to occur on the visor or that there was no anti-fog wipe available or used is unclear. The implications on the lunar surface are obvious. Visor fogging needs to be eliminated as a concern, especially if a contingency situation occurs where the crewmember is physically exerting him or herself for extended periods of time.
6. **Improve peripheral vision by adding neck ring (movable joint).** The surface crewmembers stated, “You would always have to turn your body [and the suit] to see to the side.” The astronauts’ inability to see their feet during lunar operations, partially due to the large camera mounted on their chests, made working close to the suit difficult at times. Helmet design should allow the astronauts to see their feet while working and traversing the surface of the moon. Another participant concern was the inability to see their arm during a fall to the side, which occurred with some frequency. A movable neck ring, such as the Navy deep sea diving helmet with rotating neck ring, is a good option and should be considered in the new suit design. One lunar crewmember added a slightly different experience: “I never found walking and running difficult for the same reason it is not difficult on Earth, i.e., your brain integrates location of the potential obstacles with where your foot will land in order to avoid those obstacles.”

7. **Develop a reliable Heads-up Display (HUD) displaying consumables information, limited biomedical (BIOMED) data, navigation and position data on demand.** The crews felt the HUD should primarily present the operational information that you need in an instant, e.g., if you want to see oxygen consumption, you say “oxygen” and it appears on the display. Crew did not feel a pressing need to know their heart rate, metabolic rate, or other physiological information during an EVA as in a continuous display. However, a heads-up display would be acceptable with limited physiological information on demand. Certain flexibility in reprogramming should be possible in anticipation of greater demand for information with longer and more complex EVA sequences. A concern expressed by one participant was to avoid increasing the complexity of the system to the point of reducing its reliability; however, the other crewman and telemetry and communication links provide a clear backups to the HUD information if needed.

8. **The lunar boot functioned well and does not need to be improved.** The boot was very comfortable; however, it was slippery on rocks or boulders that had some regolith covering that reduced friction. Generally this was not regarded as a problem during the surface operations. Concerns regarding “slipping” in the moon regolith were unfounded. The lunar regolith has a high, gross coefficient of friction and is well packed beneath the upper one cm or so of loose material. This property helped maintain the crewmembers footing despite its “slippery” or “loose” appearance. There was not concern about ankle sprains or injuries with falls due to the lunar soil although one crewman strained a shoulder with extreme exertion and another noted some slight discomfort at the site of an old knee tendon sprain with extended side-hill traversing.

9. **Use a self-sealing pressure garment within the suit in case of puncture.** EVA suit puncture hazard was a primary concern of the lunar astronauts, although the risk was considered low. Astronauts suggested that protecting suit occupants from a break in suit integrity was appropriate for future research and development activities. However the trade-offs for this need to be considered carefully relative to mission rules if there is a puncture and emergency regulation of suit pressure and the availability of rover consumables, etc.

10. **A drink bag should have capability to contain a high-energy liquid in addition to having a bag with plain water.** The A7LB suit had a 15-ounce drink bag, an amount
considered insufficient for the crews on the surface. Typical lunar surface activities may last up to 7.5 hours, but the total time in-suit from don-to-doff could be up to 10 hours. The astronauts strongly agreed the amount of liquid beverage contained in the suit needed to be increased for future crewmembers, including separate capabilities for plain water and a non-caffeinated high-energy drink. In addition, pre-donning checklists should include a standard procedure to load up on water, plus and adequate urine collection device (see below).

11. **Develop a better in-suit Urine Collection Device (UCD) that will work in 1/6 g.** The UCD provided to the crewmembers for use in the suit was a device requiring proper fitting of an elastic connector that worked for some and did not work for others. Urine leaks sometimes resulted in skin irritation. In one case, the elastic connector was too tight on the first EVA, resulting in some injury during forced urination. This problem was solved for subsequent EVAs by stretching the remaining connectors on the LM hand-controller between EVAs.

12. **The suit should be a low pressure (3.50 psia), single gas system.** Referring to recommendation #3, the crews stated that testing a lower pressure suit should be considered but suggested a lower pressure of 3.50 psia at 100% oxygen. Reducing suit pressure to ~3.0 psia (sea-level oxygen partial pressure) might be considered with a pure oxygen system. The risk of a suit leak could be mitigated by an emergency regulation of oxygen flow to maintain 3.0 psia.

13. **Protect the suit zipper function.** The Apollo A7LB suit was a single zipper system, unlike the Gemini suit which was a double-zipper system. The lunar dust was difficult to clear from the zipper and impaired normal function on each subsequent lunar EVA for some missions. Other missions had no problems with adequately cleaning the zipper. The abrasive nature of the dust scored the metal connections, primarily circumferentially on the bearing surfaces. The lunar dust exposure did not result in a breach of the sealing capability of the suit however repeated exposures may increase this risk.

4.2 Lunar Surface Operations

Among the lunar surface operations recommendations, crew scheduling, feasibility of surface activity commencement, and airlock/hatch design was given particular importance for the exploration architecture. The key recommendation is that because EVA efficiency is extremely valuable with respect to freeing the crew to due what humans do best, i.e., we must use crew experience and training to react instantaneously to new and unexpected situations and to use their brains, eyes and hands to take advantage of that experience and training. Routine and repetitive tasks should be as automated as possible, particularly those tasks related to the determination of position and to sample and other science and operational documentation.

14. **Schedule crews for two Lunar EVA (LEVA) days on and one day for maintenance, alternating crews throughout the week.** The surface walkers were adamant that surgeons protect the future lunar crews from overwork. Multiple factors allowed the Apollo lunar crews to work and stay awake for long periods of time during
their relatively short stay: disruption of normal circadian rhythm influencing wake-sleep cycles; loud ambient noise levels in the lunar module (LM) (the exact background noise level was not measured according to Jerry Goodman, Apollo vehicle engineer); and crew psychological state, i.e., the lunar astronauts were excited considering their current circumstances. The ability to sleep varied significantly. For some sleep was described as very restful, but for others it was described as a couple of hours of “nodding off” on the lunar surface. The astronauts stated that to optimize crew performance for extended stays on the moon, the schedule should never allow for more than two days of LEVA consecutively without a day of rest or for the alternation of EVA teams, with one acting as support on the day of rest. On extended stays, one day per week would be considered an intravehicular activity (IVA) day spent performing suit maintenance or planning and preparation for future field activity. A crew of four could alternate this schedule thereby protecting the crewmembers from overwork.

**15. The hatch and ingress corridor should be sized appropriately for an inflated 1/6 g pressure suit.** A curious finding during the background research involved reviewing the individual crewmembers metabolic activity during their lunar surface activity. All the crewmembers had notable increases in their metabolic rate during the last 30 minutes of their 3.5 to 7.5 hour LEVA. The initial assumption was that the crews were deconditioned from their micro- and partial-gravity exposure thereby reducing their exercise capacity. However, the crews’ stated sudden increase in energy expenditure had to do with the hatch design on the LM: the pressurized suits were too big and bulky to get into the hatch without bending and twisting their bodies. The position of the display keyboard above the hatch also prevented the crews from placing their hands in this area to gain leverage to pull themselves into the LM. This activity usually took several tries to ingress the LM and was quite a fatiguing process. Jerry Goodman, an Apollo vehicle engineer who helped with the LM hatch design, identified that the problem occurred before the vehicle arrived on the moon. Apparently the hatch design and pressurized suit design, although dependent and initially corroborated, later changed without being communicated to the other. The LM hatch size was decreased and the suit size increased and this went unrecognized until the crews attempted ingress to the vehicle on the moon.

**16. An airlock may make ingress/egress easier and will also be a good idea from a dust control standpoint.** Designing an airlock to separate the vehicle hatch from the habitation area could decrease the risk of tracking lunar dust into the lunar module.

**17. Surface activities can begin once operationally feasible after landing.** Crews generally felt a little “wobbly” upon stepping on the moon, but this was attributed to adapting to the EVA suit CG and the partial gravity rather than the neurovestibular dysfunction experienced by crews upon return to the 1 g environment. This statement had been reported in the literature and needed to be explained by the Apollo crewmembers to determine if this would be a problem for lunar crews in the future. Coordination seemed to improve steadily during first couple of hours on the surface. The crews did not experience recognizable problems with spatial orientation on lunar landing. This was a concern operationally as experience with rotary wing pilots suggests spatial disorientation and conditions known as “brown out” have contributed to mishaps. The commander and
lunar module pilots reported similar conditions during landing operations on several missions but did not experience recognizable spatial disorientation.

18. **There is no special training needed for 1/6 g EVA’s other than a familiarization session.** The astronauts stated the limited training they received using the Partial Gravity Simulator (POGO) and parabolic flight aircraft was sufficient for preparing them for lunar EVAs. Future lunar crews would do well to use this as lunar familiarization training but should not engage in elaborate partial gravity training devices or environments as the human body quickly adapts to the 1/6 g environment of the moon.

19. **Limit navigation into craters with a slope < 20-26° slope.** Aside from the risk for injury on slopes greater than 20-26°, the crews reported that they had to use a side-stepping approach going up and down sloped terrain because of the limitations in suit mobility. This motion often placed the inertial mass of the suit and crewmember on one leg, which would tire after repetitive loading, either uphill or downhill. The slope of the terrain affected the ability to perform this motion and the crews estimated that 20-26° was the safe limit unassisted.

20. **Crews requested that an automatic position determination device be available to aid navigation on the lunar surface.** All sorts of ambiguities exist on the moon, e.g., slopes, terrains, sun shadows, and bland environments. With the undulating terrain, it was very easy to lose known points of reference and geographic orientation despite being well versed in the two-dimensional topography. One lunar crewmember admitted to spending twenty minutes trying to re-orientate during the surface traverse. A navigation system available on the suit HUD and/or rover would be very helpful and save time during surface operations.

21. **Ladder rung height and width on the LM were good but the glove did not allow adequate grip for safety.** Crews were able to ascend and descend the LM ladder without difficulty and felt the rung height and width were easy to use. Their only concern was related to the inability to adequately grip the rung or side rails due to the limitations in the glove (see EVA suit section). Ladder height could be a concern if the glove issues are not addressed, especially if the crewmember is carrying equipment or an individual up the ladder.

22. **Ensure adequate water and food are available before and during lunar EVA.** Lunar EVA ranged from 3.5 to 7.5 hours. Total in-suit time for surface operations averaged 10 hours. The LM atmosphere was similar to the CM at 5.0 psia and 100% O2 therefore no EVA pre-breathe period was required. It is generally recommended that humans should drink 4-6 ounces of fluid for every 30 minutes of moderate exercise to maintain adequate hydration status. The Apollo crews stated that they became thirsty and hungry during their LEVA and suggested making available adequate amounts of high-energy food and plain water.

23. **Lunar EVA should be performed as one continuous event.** The question was raised regarding LEVA and whether it should be broken down into two shorter duration events allowing the crew time to hydrate and replenish energy stores, etc., or as one continuous
event. The astronauts’ inputs overwhelmingly supported the later choice as the suit and vehicle prep time for LEVA take up an unreasonable amount of crew time.

24. **Risk factors for injuries identified.** The Apollo astronauts were queried about risky behaviors on the lunar surface or conditions that could predispose them to injuries. Overall, the crews felt the injury risk was low due to the partial gravity providing considerable time to react to a fall and the relatively short distance to fall considering their lunar weight was 1/6 their Earth weight. They were quick to mention that the videos of their falls on the moon were misleading, and that it did not hurt to fall. However, the crews pointed out that their inertial mass did not change on the moon. Given the EVA suit/PLSS (~194 lbs. on Earth) and crewmember mass and right set of circumstances listed below, sufficient energy could be applied to a joint or extremity to cause injury.

   a) *Navigation into terrain or craters with slopes > 20-26°.* A fall on sloped terrain may be well tolerated unless the crew was moving or carrying an external load, such as equipment or rock samples. Although the exact angle of the slope was an estimate, the crews remarked that stable footing was limited and leg fatigue would become more pronounced in terrain steeper than approximately 26°. Lack of suit mobility, primarily at the hips, made getting in and out of steep terrain difficult. Another concern was the lack of peripheral vision in the suit and the inability to see where an outstretched hand might land. Hand or wrist injuries were more of a concern for some of the crewmembers than lower extremity injuries. The ability to estimate crater dimensions was compromised as mentioned by one crewmember in the following statement: “Reflective light in the shadows isn’t as evident as on Earth. Craters did appear steeper visually. But we knew we had to go down into that crater, so it gave us concern.”

   b) *Rover activities.* The safety harness took roughly three minutes to fasten and some crews opted not to engage the buckle. The astronauts stated that the lunar module pilot in the right seat was at particular risk of falling out due to the undulating terrain and often being tilted downward and out the vehicle.

   c) *Falling from a height.* Falling from the rim of a steep crater was a concern in some instances. Ladder height on the LM was less than six feet, but it became a concern with the poor glove grip mechanics. Mention of the proposed LSAM ladder height ranging from 20-28 feet drew sighs and obvious concern for injury.

25. **To ensure operational success and optimize performance of the crews, allow adequate time to practice mission activities in a variety of environments including analogs that allow preparation for off-nominal events.** The Apollo astronauts used at least five different 1 g analog environments for training and testing equipment. The crewmembers stated that training in a lunar analog environment prepared them for actual lunar surface operations. They also indicated that this training gave them confidence under nominal circumstances that they would be well prepared for off-nominal events.
26. Plan the operations on the surface so that you protect the crews from themselves. This recommendation relates to the earlier recommendation about protecting the crews from overwork and burnout. Adequate time is required for the lunar crews to have mental and physical rest during and between LEVA to prevent mistakes and reduce the risk of injury.

27. With extended operations on the moon, establish all the experiments in the first week. Related to the previous recommendation, the Apollo crewmembers were sensitive to the fact that lunar surface operations are difficult and demanding. Astronauts with longer surface-stay time would be more likely to make mistakes in procedures or handling equipment. Therefore, it would be good practice to deploy all the experiments and heavy load activity within the first week of a lunar stay to minimize error and injury risk.

28. A robot should perform routine, systematic, repetitive, menial tasks (may help prevent repetitive use injuries). Physical tasks, such as surface drilling, moving equipment, and setting up experiments should be performed by automated systems where possible to minimize repetitive use injuries and free up crewmember time on the surface. Examples of overuse injuries include medial or lateral epicondylitis in the elbow (tennis or golfer’s elbow), DeQuervain’s tenosynovitis at the wrist, and shoulder rotator cuff injuries. These overuse injuries have been reported in astronaut training. Other overuse injuries seen in microgravity EVA include fingertip and fingernail trauma. Repetitive use also poses a risk of associated space suit wear and tear.

29. The Rover should have the ability to recharge your suit. The crews felt they could have performed longer LEVA but were limited to the consumables in the suit. A remote recharge station in the field or placed on the rover could potentially extend surface activity duration or be used in the event of a suit incident, such as a leak.

4.3 In-flight Illnesses

30. Low back pain should be treated with aggressive pre-mission and in-flight core strengthening program. Some crewmembers complained of significant low back pain (LBP). LBP was noticed early on in space flight by >70% of crewmembers. Symptoms were relieved by curving back into the fetal position. Aspirin and other analgesics provided little to no relief. This has been a consistent finding throughout the space program. Etiology is unclear but probably related to stretching of the fibers of the intervertebral disc’s annulus fibrosis. Interestingly, the crewmembers denied exacerbations of LBP on lunar surface or return to 1 g. The astronauts suggested developing a preflight exercise protocol to strengthen abdominal muscles. This recommendation is consistent with musculoskeletal expert recommendation that abdominal or “core” strengthening pre- and in-flight helps improve lumbar spine strength and stability and may prevent or lessen in-flight low back pain.

31. Therapy to relieve muscle soreness, primarily in the forearms, must be available (improved glove design may assist this). All the lunar astronauts suffered from some
degree of forearm soreness during their surface activities. This soreness was related to repetitive grasping-releasing against resistance in the pressurized glove. Although the soreness improved overnight, this could result in overuse injury if the crew was subjected to consecutive LEVA. Therapy, such as non-steroidal anti-inflammatory medication, heat packs, and massage were offered as solutions by the crewmembers. The overall solution in their mind, however, was improving the glove design and adding mechanical assist with repetitive grasping-releasing motions.

32. **Constipation: improve the waste management collection system.** Constipation was related to diet (low residue), low fluid intake, and waste management problems. Individual crewmembers intentionally “constipated” themselves with Lomotil in order to reduce the frequency or prevent bowel movements (BMs). One Command Module Pilot (CMP) went an entire 6-day mission without a BM.

33. **Screen for CAD prior to selection for lunar missions.** The arrhythmia experienced during LEVA in one Apollo lunar crewmember was presumed to be related to hypokalemia (low serum potassium level) and dehydration on the lunar surface. This forced subsequent crews to take potassium supplements, which caused loose stools. Underlying coronary artery disease (CAD) was found years later as the cause of arrhythmia in this crewmember. Current CAD screening for ISS crewmembers is much more sensitive than the screening technology in the 1960s and should detect this condition in astronauts.

34. **A physician crewmember would increase the comfort level among the crewmembers and can be cross-trained to do other activities.** This was a consensus statement among the crewmembers regarding extended duration lunar operations. The Apollo crews had limited medical training and relied on input from the ground flight surgeon for medical issues (if they even acknowledged that a medical issue occurred). A physician astronaut could be cross-trained to carry out mission related activities, as demonstrated by Skylab, Space Transportation System (STS), and NASA-Mir programs. One Apollo astronaut remarked, “Hell, if they can take a naval aviator and train him to do geology [on the moon] they sure as hell can train a doctor to do useful things.”

35. **Adequate preventive measures and treatment for diarrhea must be available.** Another consensus statement by the crews was related to the bad experience using the Apollo waste management system. Unless this system is improved, loose or liquid stool contaminants in the cabin is very difficult to manage and clean. Fecal-oral contamination and infection also becomes an issue. Therefore, medications and/or dietary measures must be available to prevent its occurrence.

4.4 Medication/Medical Kits (Appendix D)

36. **A card is needed in the med kit to inform the crew of the medication duration, indication, and interaction with other meds.** Confusion regarding use of medication, and more importantly, the duration of action occurred on several missions. This prevented crewmembers from using medications properly. One Commander (CDR) remarked that
he had forgotten how long Dexedrine lasted and suggested putting a card in the med kit to inform the crew of the medication duration, indication, and interaction with other meds. Crew felt they did not want to report any medication usage or other problems because of privacy concerns (a private medical conference (PMC) was not available on the early Apollo missions). In addition to this recommendation, crew education by the flight surgeon was requested to clarify drug duration of action and potential interaction with other medication. It is important to note that current STS and ISS medical kits have this information readily available to the crews.

37. **Add non-sedating antihistamines for allergy symptoms due to lunar dust exposure.** Symptoms related to lunar dust were described like as “allergies” with runny nose, nasal congestion, and itchy, watery eyes. These symptoms gradually subsided with subsequent exposure during the short lunar stays for most crewmembers and CMPs upon return of the lunar walkers to the CM. One Apollo astronaut recommended, “Adding a non-sedating antihistamine like Claritin® to the med kit might help.” One of the Apollo flight surgeons related a story of moderately severe upper respiratory symptoms due to lunar dust exposure when he unstowed the suits after landing. These symptoms worsened with each subsequent exposure. He noted moderate elevations of his total WBC count, primarily the eosinophil levels which are commonly associated with allergic reactions. It is important to note that he did not have pre-exposure baseline WBC counts done to document if the elevation was in fact due to the lunar dust exposure. Lunar dust, however, is not an allergen but a toxic irritant, so it is unlikely that a anti-histamine would work to ameliorate the upper respiratory symptoms. This area is currently under investigation by the Lunar Airborne Dust Toxicity Analysis Group (LADTAG).

38. **Saline eye drops need to be available in large quantities** (however, an eyewash will be available as part of the environmental health kit). The lunar dust was ubiquitous in the vehicle cabin, and was very difficult to clear from the hands. Cabin fiberglass was also a problem on some of the missions. In each case ocular irritation occurred that required copious saline irrigation to treat. The crews felt that plenty of saline eye drops should be available in the medical kit for both ocular and nasal irrigation.

39. **Provide items that are needed in daily life, e.g., nail clippers, lotions, Band-Aids, etc. (Individual hygiene kit will be available).** During medical debriefs, several crewmembers noted frustration at not having items used during the course of normal daily hygiene available in the on-board kits.

40. **Sufficient analgesia to treat headaches.** Headaches were frequently reported during the missions. Crews were concerned that they may be due to elevated cabin CO₂ levels since the monitoring devices were unreliable. Headaches are one of the symptoms of Space Adaptation Syndrome²⁰ and noted as one of the most frequently occurring symptom throughout the space program. Crews used acetaminophen or ibuprofen with improvement in symptoms. The recommendation was for a sufficient quantity to supply all astronauts for the duration of their mission.

41. **Sleep medication must promote restful sleep but not be too sedating.** The sleep medication used during Apollo, Seconal, was a barbiturate. Side effects included
excessive sedation and “hangover” effect, essentially drowsiness the day after a dose. Some lunar crews described sleep on the moon as “two hours of nodding off” but were reluctant to take the sleep medication because of the sedation effect. The sleep medications, currently used by U.S. astronauts on STS and ISS, are of a different drug class and generally much less sedating while promoting restful sleep.

42. An adequate delivery system for nasal decongestants must be available for the crewmembers. Nasal congestion was experienced by most crewmembers, and was attributed to the 100% O₂ environment, dust, and viral exposures preflight. Actifed was used and provided moderate relief. Oxymetazoline (Afrin®), a topical decongestant, was unavailable for Apollo 7-13 due to packaging problems. Lunar crews stated that symptoms resolved on lunar surface after initial exposure to dust only to return when reentering the CM as the particulates floated throughout the cabin in microgravity.

4.5 Environmental Impacts

43. Consider adapting the Skylab waste management system into the new vehicles. In general, the Apollo waste management system worked satisfactorily from an engineering standpoint. However, throughout the medical debriefs the crews reported that the system required ~45 minutes from start to finish for defecation. Crewmembers had to strip off underwear requiring BIOMED sensor removal, a time consuming process. Application of the Apollo bag was often difficult. One Apollo astronaut described the process as “a complete mess” and “the only part of the whole mission that made me feel uncivilized.” Crews strongly recommended creating a device that would allow them to assume a squatting position to have a BM. The Skylab charcoal system was good for waste management as it provided both the ability for the crew to strap down to the toilet and assume the squatting position and a ventilation system that controlled odor.

However, off-nominal “output” such as loose stool or diarrhea is an issue not adequately addressed by either Apollo or Skylab systems. The urine collection system was “lousy” as the UCD frequently leaked. The crew was very concerned about voiding difficulties during critical operations. The urine bag, if used, created backpressure in the system, which contributed to one occurrence of in-flight urinary tract infection.

44. The sleep restraint system on the Apollo CM worked well and should be incorporated into the new vehicle design. The straps used on the couches allowed the crewmembers to fasten securely within the sleeping bag. Some crewmembers found wedging themselves under the couches to be comfortable. The sleep system used in the LM was adequate for later Apollo missions, with a few members commenting that the hammock was very comfortable in 1/6 g. However, other factors impaired restful sleep (See Appendix G). A few crewmembers suggested that alternatives to the hammock system would have to be created for extended duration missions. One crewmember chose to sleep on the LM floor but found it very cold and dirty with lunar dust.
45. Sleeping bag needs to be large enough for crewmembers to get both knees to their chest. The crewmembers often assumed a “fetal position” to treat low back pain and found it difficult, if not impossible, to bring both knees to their chest during sleep.

46. Thermal protective clothing or equipment should be available on board. The Apollo 13 crews suffered hypothermia in the 39°F LM they used as a “lifeboat” during the contingency return. The EVA suits were available but they chose not wear them because of the difficulty stowing and unstowing items from storage compartments. The A13 CDR and LMP offered the recommendation that a simple, light, and effective thermal blanket should be available in contingency situations.

47. Drinking water should be available during sleep periods. The CM and LM cabin was very dry prompting a frequent need to drink water, interrupting sleep. The astronauts suggested having a water bottle available next to the couch or in the sleeping bag.

48. Hot water capability for hygiene, beverage, and food preparation is essential. The astronauts felt very strongly that having the capability to heat water for routine daily dietary and hygiene use was a necessity. Cold water would be nice to have, but hot water was required. This was a position they felt was not negotiable.

49. Apollo bag aperture and capacity needs to be larger and easier to apply in microgravity. The Apollo bag was a bag that crewmembers passed stool into. Crews unanimously stated that the Apollo bag aperture was too small and the application was very difficult in microgravity. A better system has to be developed for future crews.

50. Create a device that would allow crewmembers to assume a squatting position in microgravity. The crews summed it up well with this statement: “Try pooping standing up with a bag stuck to your butt and see how you like it. Engineers will have to do a better job in the waste management design on future vehicles.”

51. Do not design the galley and waste management areas together. The reason for this recommendation should be obvious but the Apollo galley and waste management area were designed within a foot of each other. The crews frequently had diminished appetites for other reasons and did not need the added effect of odor and mess to further compromise their nutritional intake.

52. Minimize noise but do not eliminate it (earplugs are an adequate countermeasure for noise). Noise was an issue for sleep, especially on the LM, but was comforting to the crew. Non-essential communications from the Mission Control Center (MCC) were annoying and need to be eliminated during the sleep period. Simple ear plugs work well and more elaborate systems are not necessary. As an aside, in the LM sunlight was blocked with shades to aid in restful sleep.

53. Carbon dioxide (CO₂) monitoring device needs to be robust and reliable. The CO₂ monitor was frequently malfunctioning with resultant unreliable sensor readings. Crews often remarked they had headaches during the missions, one of the initial symptoms associated with elevated CO₂ levels. The faulty sensor system made it difficult to attribute
the crew’s symptoms to elevated CO₂ levels in the cabin. This problem persists today on
the STS and ISS with crews frequently reporting headaches.

54. A food warmer is desirable.

55. Astronaut participation in the design and development phases of the new vehicles
is essential. The Apollo astronauts were intimately involved with the requirement
development phase through vehicle assembly. Many attributed their mission success to
their knowledge of the vehicle systems and hardware. Astronauts associated with the new
vehicles should be involved with all phases of its development.

56. RFID tags should be considered for stowage items. Radio-frequency identification
(RFID) systems are well established in organizing stowage and retrieval of equipment
and other mission gear. This system would provide a reliable tool to locate items within
the stowage compartments of the new vehicles and track consumables usage.

57. LSAM windows should be designed to see only what is necessary for landing
and/or rendezvous with IR protection. Windows are heavy components of the vehicle
and should be designed with these requirements to minimize their mass. Crews will
require adequate protection from IR radiation exposure.

58. Design an efficient method for clearing the lunar dust from the vehicle cabin.
Lunar dust particles floated everywhere in the LM upon return to microgravity. Dust
particles floated into crewmembers eyes, nose, and lungs, which prompted the Apollo 12
crew to keep their helmets on prior to docking with CSM. The dust did not appear to be
filtered from the environment through ventilation/LiOH system although the vacuum
cleaner that was used beginning with Apollo 14 seemed to help clear the larger particles.

4.6 Radiation

59. The lunar excursion vehicle should have an active radiation detector with an
automated audible alarm that sounds when the dose rate exceeds a predetermined
level. The Apollo mission plan for a radiation event on the lunar surface was based on
incorrect assumptions. The assumption was that after Earth-orbiting satellites detected the
initial x-rays, the crews had between 15-20 hours before the solar protons arrived at the
moon. During this time the crews would be directed to make the traverse back across
the lunar terrain from the worksite to the LM, prepare the vehicle and launch off the
surface, successfully rendezvous with the CM, dock and secure the hatch, transfer to the
CM, and rotate the vehicle so that the thicker side of the vehicle faced the sun thereby
absorbing the radiation. Apollo crews did not have an active radiation detection and
alarm system on the lunar surface. Recently (2005), a solar event occurred where
energetic protons arrived at Earth within 5-20 minutes of the original x-ray detection.
(Note: We also have more information about the directionality of solar protons which
suggests crews should not launch from the lunar surface during a solar particle event.)
Obviously, the Apollo response requires reconsideration. The crews were adamant that
the lunar return crews have the capability to detect hazardous radiation levels. The EVA
suit, rover, and habitat should have the capability to provide autonomous detection and immediate response countermeasures should be embedded in these systems.

60. A personal radiation dosimeter (PRD) is a requirement for all crewmembers.
Although this was a requirement for all crewmembers, some of the Apollo crewmembers neglected to wear the device in the suit during lunar surface operations. They recommended designing it into the suit garments thereby eliminating the possibility that it would be left behind.

61. The rover should be equipped with a radiation shield. A durable and effective shield for solar protons should be available for crews on the lunar vehicle for a solar particle event.

62. Radiation protectants should be made available to the crewmembers. Recent developments in radioprotectants suggest that they may be useful to mitigate the risk of developing radiation sickness in crews exposed to solar radiation. The Apollo astronauts stated that they would consider using such compounds if exposed to radiation while on the lunar surface.

63. Create a trench with shovels or explosives to protect the crew short term in the event of a solar particle event. For radiation protection on the surface, creating a trench with shovels or explosives would be adequate to protect the crew short term. It is important to cover the trench quickly with regolith. A real-time active PRD in the suit will let you know how well you have done with regards to exposure and when it would be safe to leave the site. In-suit consumable recharge capability would have to be available also.

4.7 Performance/Human Factors

64. Recreational activities need to be made available for crews during trans lunar coast (TLC) and trans Earth coast (TEC). Trans-lunar and Trans-Earth coast were relatively “boring,” however, this was an individual experience. Crew wish they had brought recreation materials. Apollo CMPs remarked that the CDR/LMP could relax but he was always on task during this [TLC/TEC] mission phase. Crewmembers reported that they liked having the non-work related time during TLC and TEC, but wanted recreational activities available during this time. Exercise was one of the most desirable activities during this mission phase. This was also important for the CMP during lunar surface operations. Apollo crews recommended for long-duration missions within the constraints of the vehicle “make the space vehicle environment as normal as it is down on Earth.” The CEV should be as autonomous as possible. Several of the CMP’s stated that it was difficult at times to stay focused during lunar surface operations. Air-to-ground communications helped tremendously. MSFN relay was the best thing CMP had during this time. Other activities included watching the local news to make the day more similar to Earth. Delegation of routine operational “chores” and flight plan maintenance to the MCC would free the CMP to do non-work related activities, such as lunar or deep space

21
photography. The A15 CMP stated he used this time to explore deep space while on the far side of the moon.

65. Mental and physical rest plans should be introduced into extended moon stays to allow adequate rest between lunar EVA. Apollo astronauts stated, “Consider mental and physical fatigue here separately. Although there was not a lot of physical fatigue [during the lunar activity], the mind was being used quite a bit. You can sometimes wear your brain out before your body is fatigued.”

66. Mission focus should be project-oriented and not timelined. The Apollo lunar surface crews lamented that the timeline on the moon was very ambitious leaving little room for completing tasks in the event things did not go as planned. Future timelines should not be rushed and should allow crews to complete projects thereby minimizing error and potential injuries. A non-EVA suit related injury did occur during one mission that was a result of the astronaut trying to complete a timelined activity with a malfunctioning piece of equipment. The injury required the crewmember to use an excessive amount of analgesics for pain.

67. Use of sleeping medication should be encouraged where appropriate. The crews were generally reluctant to use sleep medication because of the side effects previously described. “There was always the fear of not being alert if an emergency came up. This can’t work for long duration stays.” A number of astronauts also felt that use of sleep medication would be perceived among their peers and ground controllers as a sign of “weakness” and chose not to use the medication despite suffering insomnia (refer to #41).

68. Countermeasures to combat mental fatigue are necessary throughout the mission. Mental fatigue pre-launch was due to the amount of non-essential training [that was not operationally oriented]. There was too much last minute emergency procedure training just prior to launch. They suggested more “normal procedure” training and less emergency procedures training during this time period. Additionally, they suggested slowing the pace of training within 1-2 weeks prior to launch. They all launched fatigued. Preflight quarantine is very valuable as it allows time for simulation training, exercise, and rest. The crew schedule should have “slack early in the mission to allow time for learning/training.”

69. Education and psychological services should be available to the crewmembers’ families. The crews commented that NASA should be more sensitive to the families needs than they were during Apollo. Family counseling was rejected by NASA when the crewmembers requested it. The crews were relieved to hear that the policy toward family psychological services within NASA has changed since their missions took place and that these services are provided.

70. Allow adequate time in the schedule for all activities. In designing future mission scenarios, the following are recommendations for optimizing operational success and crew health: allow adequate time to practice mission activities in a variety of environments where tasks are defined and duplicated just like on the moon; allow time for all
activities such as eating, resting, exercise, experiments, etc. This will take coordination with the mission planners, and is especially important to allow enough time for meals. However, the astronauts were quick to point out that during certain mission phases, such as rendezvous and docking, adequate time may not be available for these activities.

71. **Provide adequate capabilities for sleeping on the lunar surface.** Refer to the environmental section. The lunar crewmembers cited three environmental factors that impaired their ability to get restful sleep: light penetration into the vehicle, loud ambient noise level, and cool cabin temperature (particularly near the floor of the LM). Planners for the LSAM and future lunar habitat will have to correct these factors in addition to the aforementioned requirement for short-acting, well-tolerated sleep medication that does not cause excessive sedation or hangover effect. In addition, the sleep facilities will have to take into account the factors mentioned in the environmental section. In addition, the EVA suit did not provide comfortable sleep on the lunar surface. The inability to get restful sleep on the moon [because of the suit] “could have jeopardized the mission.”

72. **If a crewmember dies during the mission “cut him loose.”** Death of a crewmember during a mission is straightforward: “If a crewmember dies, you cut him loose. You can depressurize the hatch and dump him.” “Yes, if it happens, it happens...No psycho babble here.” The crews emphasized that trying to retain or recover a deceased astronaut could put the other crewmembers at risk. This plan would require working out the details far in advance of the mission so that all individuals involved, including the astronaut family members, would be prepared in the event this happened during a mission.

73. **In planning crew size/makeup, the authority structure is much more significant than crew size.** This recommendation arose out of questions pertaining to the makeup of future exploration crews with regard to number of crewmembers, male/female ratios, etc. The Apollo astronauts were unified in their recommendation to emphasize that crew make-up requirements are secondary to the crew authority structure, i.e., the commander is in charge under all circumstances. Nearly all of the Apollo astronauts were military trained and understood authority structure. This was never more evident than during Apollo 13. The crew supported their commander and insured that he was given whatever was necessary to make the correct decisions during the mission rather than trying to usurp his authority over concerns he might be succumbing to fatigue or stress. Bottom line with crew size/makeup is to make sure they understand who is in charge. The other issues are of less importance.

74. **Consider the impact on the mission control flight teams and take actions to ensure that they are rested and provided for during the lunar missions.** The crewmembers were sensitive to the demands made on the flight control teams and their families that resulted from planning and carrying out a lunar mission. They urge that NASA take necessary steps to support these individuals and their families during all phases of the mission. This included allowing enough time for sleep, family time, and training prior to and during the mission. The impact of the workload on mission control support personnel is a factor. In addition, they need defined sleep periods and time off to keep the mission functioning.
4.8 Crew Schedule

75. Preflight quarantine is very valuable for providing time for mission simulation, exercise, and rest. From an operational point of view, it removed a large number of distractions from the last three weeks of preparations and the crews were much more rested for launch.

76. The preflight training schedule should allow crews to concentrate on issues that will be used for the nominal mission. The crews wanted only mission related activities, such as simulator training and safety briefings, to occupy their time during the month prior to launch. Activities outside of training, such as exercise and rest, were often compromised during this time and should be as high a priority as any other training issue.

77. Lunar crews should have one day per week for “rest” (freedom to select their activity). During the lunar surface stay, crews should have a scheduled day of rest during each seven-day period. This day would not have timelined activities but could be used at the crew’s discretion. The Apollo astronauts emphasized that for extended duration operations, the crew will burn out if they do not have protected rest time during the week.

78. An eight hour per day sleep period must be protected in the daily schedule and must not be compromised. Crew rest time was often the subject of compromise in the daily timeline, as it is today. However, the crew strongly encouraged the flight surgeons to protect the sleep period regardless of whether the crew actually slept. Circadian rhythm was considered not to have been an issue on lunar expeditions. Regarding sleep shifting, it was not optimum to have large shifts in short periods of time. Also, the Schumann Resonance Frequency must be considered. Crews suggested discussions with experts to evaluate the risk factor influencing sleep cycles once the crew is out of the Earth’s geomagnetosphere.

79. Crews should be scheduled for simultaneous sleep periods. The initial Apollo missions had staggered crew sleep periods but were later changed to accommodate all crewmembers. This practice should be continued with the lunar return missions.

4.9 Exercise

80. Loosen the pre-mission timeline to allow adequate time for preflight conditioning program. The astronauts recognized the importance of maintaining musculoskeletal strength and stamina prior to their mission and felt that time should be set aside during the pre-flight phase to exercise. This was noted to be particularly important to some of the lunar crewmembers who attributed their ability to operate the surface drilling equipment to an aggressive pre-flight upper body strength training program.

81. A more robust (and lightweight) piece of in-flight exercise equipment is needed than the Apollo Exer-Genie. This device was the only exercise equipment available during the Apollo missions and was used by all crewmembers with varying amounts and intensities. A major limitation of the Exer-Genie was the friability of the ropes that connected to the cylinder that provided resistance and the heat that was generated with its
use. The Apollo CM atmosphere was 100% O2 and there was a real concern that the heat generated represented a fire hazard. The crews used the device at sub-maximal levels to reduce heat generation. One crewmember stated that the rope and material “frays and kinda smells” after prolonged use.

82. The flight surgeon/mission planners should not plan specific exercise prescriptions for short duration (< 14 days) mission. The crews performed exercise for rest and relaxation purposes as much as for the physical benefit. They cautioned the flight surgeons against trying to timeline specific exercises. They felt the crews should be instructed on what exercise would be beneficial and applicable for the device available, choosing what they wanted to do during short duration missions.

83. Exercise is not necessary on short trips (14 days or less) [from a fitness standpoint], however, crews demanded that the capability be available and varied as much as possible for crew “rest and relaxation” in all phases of the mission. The crews did not feel that they suffered noticeable deconditioning during their relatively short missions. However, they do not dispute the science that shows muscle and bone strength decrements with longer microgravity exposures. In the context of their short missions and lunar EVAs, they were able to perform all mission related activities without concern from loss of strength or stamina. The astronauts demanded exercise capability for the CM for rest and relaxation purposes. A couple of crewmembers also experienced minor Achilles tendonitis after return to Earth and suggested that a more aggressive lower extremity stretching program enroute to home may have prevented this occurrence. The lunar surface crews felt that their activities on the moon provided enough exercise for a short duration mission but would have welcomed a simple, robust device for stretching and forearm strengthening exercise.

84. Develop a better preflight and in-flight forearm muscle-conditioning program for lunar crewmembers. In addition to the core stabilization program as described earlier in the illness/injury section, a strengthening program for the forearm muscles before and during the mission is necessary. Upper extremity exercises, specifically to strengthen and maintain shoulder strength and stamina, will be necessary in the preflight period and during the mission. As mentioned previously, operating the surface tools in partial gravity, particularly the drill, requires more force generated from the shoulders than needed in 1 g.

85. New vehicle design should allow a variety of different exercise capabilities (hardware vs. cabin structure). The astronauts recommended examining the new spacecraft design to determine surfaces or structures within the vehicle to exercise various muscle groups. Also, a more robust (and lightweight) piece of equipment is needed. The crews performed isotonic exercises against the struts of the LM on the surface before EVAs. Another example of using the vehicle in novel ways to perform exercise included “running in place holding onto the couch,” isometrics performed against cabin structures, etc.
86. **Put as many** [exercise] **capabilities in the vehicle as possible, because it will get used.** Many crewmembers felt exercise capability throughout flight will be critical. A variety of exercises must be provided.

87. **New exercise devices should be reliable, simple, and not develop excessive heat in use.** The crew was concerned towards the end of the mission that they were going to “break the machine” and began tapering down the exercise duration and intensity to protect the equipment so that it would be available for reconditioning prior to re-entry.

4.10 **Food/Nutrition**

88. **Mission activity** (e.g., coast, rendezvous, lunar orbit, lunar OPS, etc.) **will dictate what type and how much food will be consumed.** Apollo diets offered 2100-2660 kcal/day, but the crews seldom obtained these required energy intakes. During busy mission phases, the crews often went without eating or drinking because of issues with preparing food or problems associated with the water system. They recommended that meal planners work with mission planners to coordinate easily accessible food that could be prepared quickly to ensure that crew energy needs are met throughout all mission phases. Specific examples of mission activity and appropriate food types include:

- High activity – wet packages, bite-sized snacks, canned foods
- Low activity – spoon-bowls, dry juice or meals (rehydratable) requiring mixing etc.

89. **Plain water in large quantities needs to be available for lunar EVA.** The crewmembers stated that they needed more plain water available for LEVA. As was mentioned in the EVA suit and Lunar Surface Operations section, the lunar crews often went 10 hours without a break after suiting up.

90. **Optimize diet and food intake for overall performance during long duration missions.**

91. **An in-suit non-caffeinated solid or liquid carbohydrate food source for lunar EVA would be helpful.**

92. **Design adequate space and useful area in the new vehicles to store food packs during meals.** Lack of available space and useful area to store food packs during meals made eating difficult. Food preparers need to be mindful of the difficulties associated with performing tasks in microgravity.

93. **Spicy and salty foods are preferred items in the menu.** Overall, the food lacked flavor or spice. Crews preferred the salty bite-sized snacks or other flavorful items as their taste perception changed in space compared to the preflight food testing.

94. **Allow adequate time in the daily schedule for meals.** Refer to comments in recommendation # 88.
95. **Determine how different environmental factors (e.g., O₂ concentration, cabin pressure) effect food flavor.** Foods tested preflight tasted fine but were “absolutely unattractive in-flight.” One crewmember who had flown both an Apollo and STS mission stated he had a poor experience with food during Apollo but the same food flown on shuttle was palatable and tasty. His experience raised the question of the effect of the 5.0 psia and 100% O₂ atmosphere of Apollo on food integrity or taste perception compared to the 14.7 psia and 21% O₂ of the space shuttle. The future vehicles have a proposed cabin atmosphere of 7.6-8.0 psia at 30-32% O₂.

4.11 Launch/Landing/Recovery Operations

96. **Provide adequate cooling capabilities for the crew on landing to mitigate the hot cabin contribution to crewmember seasickness.** Considerable weight loss was attributed to sweating and dehydration that occurred on landing secondary to seasickness. Inadequate cabin/suit cooling after landing was cited as the primary contributor to both conditions. The future landing vehicle must have adequate cooling capabilities for the crews. The onset and severity of seasickness will be determined by the crew’s ability to stay cool more than anything else.

97. **Ground landings are discouraged.** This was not a consensus statement among the crewmembers. A number of the Apollo astronauts, however, were adamant that a ground landing would likely kill the crewmembers. NASA has considerable experience with water landing, have never lost a crew by landing in the sea, and have a much larger margin of error for re-entry. Ground landings do not afford much error and may pose a threat to humans in populated areas with an off-trajectory re-entry profile. The dissenting Apollo astronauts, however, mentioned that we now have extensive experience via the shuttle with ground landings, and that perhaps water landings could be used to build confidence before moving forward with ground landings. It was also pointed out that the navigation capabilities to track the re-entering spacecraft were not well-developed or reliable whereas the navigation systems today are a proven technology and would ensure reliable land trajectories upon reentry.

98. **Apollo seat configuration for water landings was adequate.** The seats were adequate for re-entry despite force distributed throughout body. Impact was well distributed across the back. Couches and restraints were adequate for landing and launching from the Earth and moon in terms of side and head protection. All loose items need to be restrained; one crewmember sustained a scalp laceration after being struck in the head by an object that came loose when the capsule impacted the water.

99. **Medication for motion sickness and fatigue should be available prior to re-entry.** Scopolamine 0.3mg/Dexedrine 5mg were taken by several crewmembers prior to re-entry and again at splashdown to prevent motion sickness and to combat fatigue.

100. **Sea state should be limited to < 6-8 foot swells if recovery is to be delayed.** Most of the Apollo astronauts were naval aviators or experienced pilots with one exception. Nearly all the astronauts experienced seasickness, some reporting the onset of symptoms
within 30-60 seconds of the water landing. The crews strongly recommended that the recovery sea state be limited to less than 6-8 foot seas.

101. Have food and plain water within reach of buckled crewmembers for delayed recovery. Dehydration was a significant concern due to lack of suit or cabin cooling. Food and plain water will need to be readily available for the crews in sufficient amounts to sustain the crew until recovery teams can remove crew from the landing capsule.

102. Apollo CM hatch location and size was adequate for egress. Hatch location for landing egress was adequate. Apollo crewmembers denied having any trouble emerging from the capsule after landing. The crews offered a mixed response as to whether they would have been able to assist an injured crewmember in an emergency scenario. Crewmembers also recommended that the hatch on the re-entry vehicle open outward in response to the Apollo 204 hatch that opened inwardly preventing crew escape during the fire. However they pointed out that a hatch design that opens outward but does not seal with pressure is very dangerous, referring to the potential for cabin atmosphere leaks.

103. All control panels and switches should be within reach of crewmembers during launch and landing. Regarding the control panels and switches, all required functions were within reach during high g and zero g in the Apollo CM. This was tested in centrifuge runs in the design and development phase. The same approach should be taken for the new launch and return vehicle.

104. Training for pad abort was adequate and should be continued. The slide wire abort works. One crewmember felt the egress route under the pad room in Apollo provided a faster and safer escape route than the slide wire.

105. Crew surgeon should be on the recovery vessel and not the helicopter. The rescue crew provides all the necessary skills for safely transferring the crew from the vehicle to the helicopter. The crew flight surgeon serves his/her purpose best on the recovery ship and should not be put at risk in the recovery aircraft.

4.12 Flight Surgeon-Crew Interaction

106. Crews encouraged the Flight Surgeon to “act as more of an advocate of the crew” than treat them as an experiment. Crews often felt the flight surgeon treated them as “an experiment” considering the demands the flight plan placed on them. Lack of PMC with flight surgeon limited the crew input regarding physiological functions and medication usage during flight. After one CMP was left hanging regarding his flight status due to an abnormal lab value 3 weeks prior to launch, the CDR and CMP both felt the flight surgeon was not looking out for the crew’s “mental well being.” The CDR emphasized that “emotional stress is one of the main issues [that the flight surgeon] needs to help minimize both preflight and in-flight for his/her crew.” A number of crewmembers did state instances where their individual flight surgeon supported them above and beyond the call of duty and were grateful for their dedication to their crews.
107. The collaboration established between the current flight surgeons and Apollo crewmembers should continue and be an example to future generations.

5.0 DISCUSSION

The purpose of this study was to identify Apollo operational issues that impacted crew health and performance. The specific goals of this project were to develop or modify medical requirements for new vehicles and habitats, to create a centralized database for future access, and to share relevant Apollo information with the multitude of entities at NASA and abroad participating in the exploration effort. Secondary objectives included using this information to validate current requirements and refresh knowledge regarding lunar operations. The database has been created to complete this study, and the information gleaned is currently being shared among NASA entities. What remains is to discuss the modification of exploration medical requirements based on the experiences of the Apollo astronauts.

The only experience that the human race has with manned lunar exploration is through the perceptions and memories of the 22 surviving Apollo astronauts. As such, their experience and knowledge is a vast resource that has been surprisingly untapped. This paper has attempted to extract and archive this resource. Underlying everything from the abstract to the conclusion was the ethos of “operationally driven outcomes.” In other words, the focus was to determine how the positive and negative experiences of the Apollo astronauts can improve the mission operations of the Constellation crews. The authors diligently focused on extracting that which had potential operational relevance, so that the varied audience could come away from the paper with something tangible to incorporate into their exploration work. Also, as discussed in the Methods section, previous published data was exhaustively researched to prevent duplication of results and conclusions. Further, data contained within this paper has been reviewed for accuracy by the Apollo astronauts. Hence, the results are an attempt to achieve an untainted representation of the thoughts and recommendations of the Apollo astronauts themselves. The authors of the paper have simply acted as the “middle-men.”

There are both strengths and limitations of the ability of these results to “develop or modify medical requirements for new vehicles and habitats.” Are these events and challenges that occurred over 35 years ago applicable today? On Apollo missions, the astronauts were allowed to bring one cassette tape into space for morale purposes. Today astronauts can carry an Ipod with 80 Gigabytes and 20,000 songs. True, there are now new paradigms and new technologies, however, the authors (and the Apollo astronauts) feel that those who don’t learn from history are bound to repeat it. Just as Sun Tzu’s “Art of War” is as true and applicable today as it was in the 6th century B.C., the lessons of the Apollo astronauts will find significance and relevance with future exploration missions. Limitations inherent to this study potentially include non-response bias and the volunteer effect, procedure bias, and recall bias. Also, there are limitations to the applicability of the 107 recommendations, some recommendations are “more relevant” than others. For example, there were many recommendations regarding the waste management system.
Many of these issues have been vastly improved through years of shuttle and space station experience. These recommendations are somewhat “less relevant.” However, in general, the recommendations in the categories of EMU/EVA Suit Operations, Lunar Surface Operations, and Lunar Radiation are “more relevant” due to the fact that they are related more closely to lunar exploration and have not yet been duplicated or improved upon. In the end, the relevance of each recommendation must be considered carefully and individually.

The principle findings of this study can be broken down into broad pervasive themes and themes relevant to each of the 11 recommendation categories and subcategories. Three themes were ubiquitous throughout the project. The first two, safety and mission accomplishment, were explicit and self-evident. These two ideas are intertwined, virtually impossible to separate, and at the core of every recommendation that was put forth. The third ever-present, but almost “unconscious” theme was one of human factors, and in particular, the idea that “the astronauts are only human.” When analyzing the responses one gets the idea that the astronauts are imploring the establishment to acknowledge that they are humans, not robots or test subjects. This was evident with multiple recommendations spanning the 11 categories. For example, scheduling-related recommendations were made in 4 of the categories for a total of 23 recommendations. Likewise, 10 sleep-related recommendations were made in 3 categories and more generally, ~26 recommendations for “rest and relaxation” were mentioned in 6 categories. Further evidence for the recognition of their limitations includes multiple recommendations for ensuring adequate “self-maintenance” via exercise, nutrition and fluid intake, and a higher level of waste and personal hygiene. Finally, the astronauts made multiple recommendations (7 in 6 categories) and requests regarding Flight Surgeon/Physician advocacy and intervention. Military pilots traditionally have had an apprehensive relationship with Flight Surgeons, hence the astronauts’ appeal to seek assistance from someone who could potentially ground them should be considered significant. They even went so far as to unanimously recommend the addition of a physician-astronaut as a crewmember, with the thought being that a physician-astronaut would increase the comfort level among the crew, and could serve as a strong advocate for astronaut needs while in space. A final observation worth mentioning is that the astronauts’ recommendations were very difficult to categorize. That is, a single recommendation such as “Improve glove flexibility, dexterity and fit,” simultaneously involves operations, engineering, human factors, safety, and mission accomplishment. This brought to the forefront the uniquely interdisciplinary nature of manned space exploration and the broad appeal of this paper.

The Tables 3 through 14 list the Apollo astronauts’ 107 recommendations followed by the current status and disposition of that recommendation. The status definitions are as follows:

- **In Practice**: The recommendation is operational in current shuttle and ISS missions
- **New Requirement**: The listed requirement was created as a direct result of the Apollo recommendations
Requirement Modified  The listed requirement was revised as a result of the Apollo recommendations

Requirement Validated  The listed requirement was validated by the Apollo recommendations

OpsCon Validated  The listed operational concept was validated by the Apollo recommendations

Being Evaluated  The recommendation is actively being analyzed for future requirements

Consider  The recommendation is known by involved parties, but there is no formal review for acceptance or rejection

Rejected  The recommendation has been evaluated and subsequently rejected as a requirement

The emphasis of the recommendations varied through each of the 11 categories:

EMU/EVA ISSUES

EMU/EVA recommendations centered first and foremost on improving the functionality of the suit first and foremost and then focused on improving both the human factors integration as well as specific safety features. The most adamant of the suit recommendations and a consensus statement was to improve the dexterity of the glove. This recommendation had mission accomplishment and safety as the driving concerns. Similarly, the astronauts recommended increasing ambulatory and functional capability through increased suit flexibility and decreased mass and internal pressure. Theoretically this will have the added benefit of decreasing fatigue as well. The human factors recommendations revolved around consumables and excretion. They recommended in-suit access to large amounts of high energy liquids and plain water, a Heads-up Display with consumable, biomedical, and navigation information on demand, and an improved urinary collection system. Safety concerns revolved around redundancy being built into the suit. In particular, they suggested a system to prevent helmet fogging under all circumstances, a self-sealing pressure garment in case of puncture, and a system to protect the zipper from abrasive lunar dust.

Spacesuit technology has improved over the years through shuttle and ISS experience, however, only the Apollo astronauts have the experience of operating in the lunar environment at 1/6 gravity. As such, their insight is very relevant to exploration requirements.

As can be seen in the Table 3, the EVA Systems Project (ESP) and the Human Research Program (HRP) via the EVA Physiology Systems and Performance (EPSP) element is quite active with this set of Apollo recommendations. The EPSP and ESP is aggressively evaluating multiple recommendations and considering several others. EPSP has a systematic test plan that will address suit related issues and result in specific data backed recommendations for the optimal suit weight, mass, pressure, center of gravity, and kinematics (mobility) for lunar operations. Additionally, the EPSP and Exploration Medical Capability (ExMC) team have addressed the UCD issues and have developed improvements to the Maximum Absorbent Garment (MAG).

LUNAR SURFACE OPERATIONS

Recommendations for lunar surface operations revolve around human factors, safety, and operational efficiency. Human factors and safety considerations were particularly intertwined in this category. A recurrent comment by the Apollo astronauts about operations on the lunar surface was an overwhelmingly packed schedule. For extended operations, the astronauts were adamant about decreasing the workload in the schedule. They suggested a maximum of 2 LEVAs within a 3 day period and a schedule with flexibility and “breathing room” built into it. They also commented that surface operations could begin once operationally feasible, that LEVAs should be one continuous event with ample food and liquids available before and during the event, and that the schedule should be front-loaded to minimize error and injury. Major risks identified were falls, rover operations, and navigating slopes in excess of 20-26 degrees. With suit functionality improvement, some of the risks identified will be reduced, one example being upper extremity injuries due to inability to visualize placement of an outstretched
arm. To increase operational efficiency the astronauts recommended using HUD technology, robots for repetitive tasks, and the rover to recharge suits. They also felt that for extended operations, LSAM ingress and egress portals must be closely scrutinized. They emphasized with a consensus statement that the hatch size must comfortably accommodate pressurized suits and that engineers consider an airlock. In general, they felt that the familiarization training with partial gravity devices or aircraft, such as the POGO or parabolic flight, and analog training was sufficient.

The longest any of the astronauts spent on the moon was three days yet many of their recommendations inferred problem areas for extended lunar stays. Therefore, this category in particular is very relevant to future lunar exploration. Also, many of their recommendations are straight forward and difficult to counter. For example, guarding against overwork and ensuring food and water availability seems obvious, but implementation may not as straight forward during planning phases. Surprising recommendations included the astronauts’ acknowledgement and requests for new technology (such as an iPod®) that one might have thought to be outside of the paradigms of these mostly 1960s and 70s era astronauts. Also, multiple recommendations have already been implemented by virtue of shuttle and ISS operations.

IN-FLIGHT ILLNESSES

Recommendations addressing in-flight illness focused on pain, gastrointestinal dysfunction, and preventative screening. In particular, treatments or preventative measures were recommended for lower back and forearm pain and soreness, constipation and diarrhea, and heart disease. The two consensus statements in this category included therapy to relieve muscle soreness, especially in the forearms, and to include a physician crewmember to increase the comfort level among the crewmembers. This category also demonstrated the inter-disciplinary nature of space operations. For example, it was discovered that crewmembers intentionally constipated themselves with medications to reduce or completely prevent the need to use the poor waste management collection system. Another example is the forearm soreness. A well-designed glove would render this complaint a non-issue.

This category although significant, has less relevance due to improvements that have been implemented during Skylab, Shuttle, and ISS operations. All issues except the consensus related statement regarding a physician-astronaut are accounted for in Table 5.

MEDICATION/MEDICAL KITS

Recommendations focused on medications that would have improved operational efficiency and comfort. Recommendations for kit contents included allergy medications, saline eye drops, standard toiletries (nail clippers, lotions, etc.), headache analgesia, efficacious sleep medications, and an efficient decongestant delivery system. All of these items are currently accounted for or improved upon (i.e. eyewash is included in addition to saline drops) in the Constellation requirements.

ENVIRONMENTAL IMPACTS

Human factors and operational design were the two foci of the Environmental Impacts recommendations. Recommendations addressing human factors dealt with waste management, sleep, and consumables. The astronauts unanimously recommended the adaptation of the Skylab waste management system. They also wanted to see a device to allow for squatting for bowel movements, felt that the Apollo bag aperture and capacity both needed increasing, and would prefer that the galley and waste areas be separated. To foster restful sleep, the astronauts recommended minimizing environmental noise, having water available during sleep, increasing the sleeping bag size to allow for the “fetal position,” and the incorporation of the CM sleep restraint system. Hot water capability was deemed essential and non-negotiable via a consensus statement. A food warmer was also considered desirable. Operational concerns centered on engineering redesign, a contingency input, and increasing efficiency. First and foremost, the crewmembers consensus was that astronaut participation in design and development is essential. Another consensus statement was to incorporate more reliable CO₂ monitors. They also felt that the LSAM windows should be as small as possible and that there should be a system for clearing lunar dust from the cabin. A consensus statement resulting from the experience of Apollo 13 was to include thermal protective gear in the event of a contingency. The last recommendation was to utilize RFID tags for stowage items.

The recommendations brought to light some points that would have been missed just as they were during Apollo. For example, as a result of the recommendations thermal
protection is being added to the crew equipment. Other changes and additions are shown in table 7.

Figure 6. Environmental Impacts

RADIATION

Apollo astronauts were concerned about radiation detection and contingency plans. They stated that all vehicles, habitats, and suits should have radiation detectors and dosimeters built into them. They also recommended that the rover should contain a radiation shield, lunar astronauts should have the ability to create trenches for solar particle events, and that pharmacological radiation protectants should be made available.

Thanks to Skylab, the shuttle, and the ISS, there is a large body of operational knowledge regarding radiation in low Earth orbit; however, radiation on the surface of the moon is not as well defined. The Apollo astronauts were clearly concerned about radiation, and acknowledged that more research needs to be done in this area.

**Figure 7. Radiation**
Performance/Human Factors/Crew Schedule generated many recommendations. The recommendations can be broken down into mental (and physical) health concerns and operational concerns. The mental health recommendations dealt with rest and relaxation time, sleep, and psychological preparation. A rest and relaxation consensus statement called for 1 day per week for astronaut discretionary use and the implementation of mental and physical rest plans. Some astronauts also requested recreational activities to be available during down time. Interestingly, the astronauts also displayed empathy and concern for the workload of the mission control teams in the form of a recommendation. Regarding sleep, the astronauts stated that the crew sleep periods should be concurrent, that adequate capability for sleep on the lunar surface should be provided, and that sleep medication use should not be stigmatized. They also unanimously agreed that a minimum of 8 hours of sleep per day must be protected. Regarding psychological preparation and well-being for families, the astronauts unanimously agreed that educational and psychological services must be available to them. The Apollo astronauts also recommended that in the event a crewmember death during the mission, all involved must be prepared to “cut them loose.”

</tbody>
</table>
CREW SCHEDULE

Operational concerns overwhelmingly focused on scheduling issues. Crews stated that the preflight quarantine was very valuable and that the preflight training schedule must allow the crew time to focus on the mission. They also said that throughout the mission including preflight, countermeasures for mental fatigue are necessary and that adequate time for activities must always be provided. They recommended that the mission focus be project-oriented and not time-lined. The final recommendation emphasized the importance of the crew authority structure over all other concerns of crew resource management or crew composition.

CREW SCHEDULE

Consider, 5, 100%

Figure 9. Crew Schedule

EXERCISE

Recommendations regarding exercise centered on scheduling concerns and the exercise equipment. The Apollo astronauts stated that exercise isn’t required on trips less than 14 days from a strength/endurance perspective and that exercise prescriptions for short trips were likewise not necessary. Unanimously they stated that the opportunity to exercise must exist for rest and relaxation during all phases of the mission. They said exercise should be required for longer duration lunar missions but research still needs to be done to determine if 1/6 g alone provides any benefit to the musculoskeletal or cardiovascular system. They said that scheduling needs to allocate time for preflight conditioning and that a preflight and in-flight forearm conditioning program be included. The exercise equipment, Exer-Genie, on Apollo missions was considered sub-par, and the astronauts
unanimously declared that new exercise devices should be reliable, simple, and safe. They also encouraged that as much exercise variety be built into the vehicle and equipment as possible.

</table>
FOOD/NUTRITION

The food/nutrition category garnered a number of recommendations. The astronauts commented on nutritional requirements, taste preferences, logistics, and operations. The astronauts unanimously agreed that mission activity dictates the type and amount of food that will be consumed. They also were unanimous in recommending ample water availability for LEVAs and stated that an in-suit source of carbohydrates would be helpful. They recommended that for long duration missions diet and consumption schedule would need to be carefully optimized. Regarding food flavor, the astronauts preferred spicy and salty foods and suggested research into how different environmental factors affect food flavor. There was unanimous agreement that Operations needs to schedule adequate time for meals and the new vehicle should allocate space to store food packs during meals.

### FOOD/NUTRITION

![Figure 11. Food/Nutrition](image-url)
LAUNCH, LANDING, AND RECOVERY OPERATIONS

Launch/Landing/Recovery Operations was broken down into discussions regarding a sea recovery, operations, and engineering ergonomic concerns. Many of the astronauts discouraged ground landings and stated that cooling capability on landing was required to mitigate sea sickness. They also stated that food and water must be within reach of buckled crewmembers in the event of a delayed recovery. Additionally, they stated that the Apollo seats were adequate for water landings and that medications for motion sickness and fatigue should be available prior to re-entry. Operationally, the Apollo astronauts wanted to see a flight rule to limit sea state landings to <6-8 foot swells if recovery is to be delayed. It was also stated that the crew surgeon best fulfills his duty from the recovery vessel not the helicopter. Training for launch pad aborts were thought to be adequate. Regarding engineering ergonomics the astronauts felt that the CM hatch location and size were adequate and that all switches and panels should be reachable during launch and landing. With regards to the landing suits, the crews were in the constant wear garments, not the pressure suits. At some point the program decided that separation of the SM from the CM was not a true “change of configuration” that posed a significant hazard, hence they did not feel the need to wear the pressurized suits.

FLIGHT SURGEON-CREW INTERACTION

The crews stated that the flight surgeon needs to act as an advocate for the crew and that the collaboration resulting from this interaction between the flight surgeons and the Apollo astronauts should continue and be an example to future generations.

SUMMARY DISPOSITION of RECOMMENDATIONS

Overall, the 107 recommendations received were dispositioned into the following categories: consider, being evaluated, new requirements, requirement being modified, requirement validated, rejected, and in practice. The specific distribution of the recommendations is detailed in Table 15.

Note that a few recommendations were broken down into multiple recommendations. Therefore, 113 recommendations were dispositioned as opposed to 107. It was determined that cumulatively 23% of the recommendations resulted in a validation or modification, or development of a new requirements or was currently in practice. While 77% of the recommendations are being considered or evaluated. Of this 77%, being considered or evaluated, there is potential for additional requirements to be further modified, validated, or created. Hence, we see that many of the experiences of the Apollo astronauts have been considered relevant, and have impacted the exploration architecture.
Figure 14. Overall Status of the Apollo Suggestions
6.0 CONCLUSION

The Apollo Medical Operations Project was designed to identify relevant medical operational issues from the Apollo mission issues which had an impact on crew health and/or performance. The goals of this project were to develop or modify medical requirements for new vehicles and habitats, create a centralized database for future access, and to have the capability to share relevant Apollo information with various entities at NASA and abroad participating in the exploration effort. Secondary objectives included using this information to validate current requirements and refresh knowledge regarding lunar operations.

The theme of the Apollo astronauts’ 107 recommendations is *res ipsa loquitur* or “the thing speaks for itself.” As one of the astronauts said, “Start with what worked on Apollo, and then prove to me why something should be different.” The authors likewise feel that the information gleaned from Apollo astronauts’ operational experiences is relevant even though the exploration missions have objectives that differ. In other words, the exploration missions are not “Apollo 18.” The recommendations contained within this document have broad implications for mission directors, engineers, astronauts, physicians, administrators, and anyone involved in exploration missions. Organizations within the Space Life Sciences Directorate such as the Human Research Program (HRP) have taken action in response to many of the recommendations. Currently, operational solutions to mission relevant problems and issues identified by the Apollo astronauts which affected crewmember health and/or performance are being developed. The HRP has funded specific programs, such as the EVA Physiology and Performance Project (EPSP), Exploration Medical Capabilities (ExMC) and Exercise Countermeasures Program (ECP) to develop hardware or systems based on the results of the Apollo Medical Operations Project. It is important to point out that the EPSP members are currently contributing to the Lunar Architecture Team (LAT) phase 2 study which is addressing issues such as crew habitat concerns, airlocks/suitlocks, suit and habitat radiation protection, EVA navigation and guidance, suit design, and operations.

It is the authors’ vision that the recommendations presented here be evaluated by all relevant departments and that the appropriate recommendations become requirements resulting in improved mission operations. Currently, 23% of the recommendations have resulted in development, modification, or validation of requirements or are currently in practice, 77% are being considered or evaluated, and no recommendations have been rejected. It is incumbent on all who read this document to keep the 77% from falling by the waste side.

Future work in this area may includes ongoing dialogue with the Apollo astronauts and additional questionnaire follow-ups to solicit their opinions regarding specific mission operations and implementation of their recommendations. The authors hope that the operationally relevant outcomes of the Apollo Medical Operations Project and other studies like it will contribute significantly to the success of the nation’s vision and the Constellation goal of exploring the moon, Mars, and beyond.

Appendix A
Apollo Summit Non-Attributable Report

Source: Medical Mission Debriefs
Topic: Lunar EVA
Issue: heart rates
Description: Both CDR and LMP thought their EVA heart rate peaks were about 20 bpm below what monitored rates showed.
CDR: You will run wherever you move to on the Moon. So plan every 1200 feet to stop and rest for about 2 minutes.

General to a
Comments: Dr. Berry noted that during the short LM rest periods, the heart rate did not return to a resting rate before activity was resumed. CDR pointed out that during some of the 'rest' periods, they were actually working hard, even though they weren’t running. There were always tasks that needed doing to meet the timeline.

Resolved:
If Resolved how, when, where?
Additional Questions: Should lunar activity timeline be project oriented?
Summit Topic: Yes

Source: Medical
Topic: Lunar EVA
Issue: workload
Description: LMP: Walking around was a low effort, "near the very lowest end of what you do on the bike."
"You can’t seem to work too hard up there." Work is limited by the pressure suit.
Max effort was either carry out the ASLEP or coming out of the crater.
Those max work levels were "about equal to a little more than half as hard as you go fast on the bike."
CDR: Two times he was tired, one of the times more thirsty than tired, the other was a long run from Sharp crater over to Halo crater." Carrying weight (rocks or equipment) and climbing out of a crater required pacing and a stop of 1 minute and a "shot of that intermediate cooling" was enough to go on. Spent 2 hours in the LM unnecessarily when they could have been continuing the EVA.
CDR: never felt heart rate go above 100--could have gone all day at that work level
Second EVA involved more arm work, working with equipment, always moving.
Heart rates higher on 2nd EVA. While running CDRand LMP had HR > 170.
LMP: Felt like 125 or so while running.

General Comments: Hands tired after 2nd EVA
Resolved:
If Resolved how, when, where?
Additional Questions:
Summit Topic: Yes
Source: Medical Mission Debriefs
Topic: Lunar EVA
Issue: Physical Effect
Description: 

a) Effort during LEVA was described as minimal or low-compared to exercise effort on bicycle pre-flight

b) Only increase in physical effort came with climbing out of the crater and long run between Sharp crater and Halo crater
- only required crew to rest for approximately a minute before resuming activity.
- HR averaged 100 bpm, varied with exercise between 120-170 bpm, during the 2nd LEVA
- effort was similar to POGO training activity
- crew felt they could have easily performed EVA for an additional 3-4 hours

c) Sweat was minimal in the suit and was greatly reduced by adjusting vent/cover to max
- hands did sweat in the gloves secondary to lack of cooling
- glove liners were soaked with sweat; apparently learned from Apollo 11 experience

d) crew fell 1-2 times during LEVA, had no problems getting back up

e) shadow pattern made slopes look much steeper than it actually was

f) able to walk down 13 degrees decline to surveyor probe after problem with slope angle resolved

g) surface is not like a desert but more like an ocean with troughs and waves.
- Not level, more undulating
- navigation was difficult

h) LEVA was limited by fatigue, fluid intake and fluid in part from the suit, not physiological limitation

i) Crews worked during surface rest periods, unbeknownst to the ground. This accounts or the failure of their HR's to decrease while at "rest"

General Comments:
Resolved:
If Resolved how, when, where?
Additional Questions: Do the crews feel the pre-flight EVA tripping problem adequately prepared them for LEVA from an exercise capacity standpoint
Do crews need a device to better ascertain position of craters in shadows? Does this raise a safety concern?

Summit Topic: Yes

<tr>
<td>Description:</td>
<td>CDR felt strongly that the use of the Liquid Cooling Garment (LCG) by the LMP and CDR while in the LM, while preparing for and upon return from lunar EVA played a major role in reducing insensible and sensible water loss and helped them stay adequately hydrated. This led to a higher performance capability than if they had used LM air circulation for cooling. He compared the feeling of fatigue and dehydration on earth after using a backpack and air cooling when simulating EVA and the absence of such compromised condition after using the LCG for about 5 hours pre-and post EVA, while in the LM. There is a lot of metabolic work in donning and doffing the EVA suit that is not measured as there is no biomed monitoring during that time. It is important not to get behind with regards to hydration prior to beginning the actual lunar EVA. Rather than leave the suit ASAP after an EVA, some maintenance and stowage tasks are best done in the suit. It is difficult to don and doff in the confines of the LM. The LCG is very helpful during this time.</td>

Apollo Summit Non-Attributable Report

Source: Medical Mission Debriefs
Topic: Lunar EVA
Issue: EVA suit issues
Description: "perfect glove fit" But after EVA hands were very sore after getting out of suit and
gloves. Looked like "a blood blister" on every fingernail-after the first EVA.
"They ached to the point that we soaked them in an empty food bag, filled it
with water and just let our hands soak in cold water for 15 minutes." By next
morning, "we're fine," no problems during 2nd EVA, but ached at end of EVA.
At end of 3rd EVA, no problem.
Still has yellow marks under some nails during interview "that's just blood" During
Gemini, he had hand soreness which took several weeks to clear.

</table>

**General Comments:**

**Resolved:**

**IfResolved how, when, where?**

**Additional Questions:**

1. Would fewer but longer EVA be more efficient and save time?
2. Did crews bio reflect reasonable work or not? If not does this need to be addressed?
3. Did crews bio reflect hopping being more efficient than walking

**Summit Topic:** Yes
Source: Medical Mission Debriefs
Topic: EVA suit
Issue: water and thirst
Description: CMP: Felt thirsty at times. Juice consumption contributed to thirst. CDR drank most of his in-suit water during 1st EVA LMP drank most of his in-suit water during 1st EVA CDR: "Anything you can do to make it easier is going to help increase the consumption." "Particularly during busy times."

General Comments: Crew had limited H2O carrying capacity in suit.

Resolved:

If Resolved

how, when, where?

Additional Questions:

Summit Topic: Yes

Source: Flight Surgeon logs
Topic: Lunar EVA
Issue: fell
Description: fell over rock dropped camera-tired and edgy

General Comments:

Resolved:

If Resolved

how, when, where?

Additional Questions: What factors contributed to crew fatigue on the lunar surface?

Summit Topic: Yes

<td>The surface suit seemed to work well from an environmental control standpoint</td>
</tr>
<tr>
<td></td>
<td>1. No vision fogging on lunar surface</td>
</tr>
<tr>
<td></td>
<td>2. Vent / cooling were adequate</td>
</tr>
</tbody>
</table>

**General Comments:**

**Resolved:**

**If Resolved how, when, where?**

**Additional Questions:**
- What changes are planned for surface suit?
- Would any of these adversely affect those things that seemed to work well?

**Summit Topic:** Yes
Appendix A
Apollo Summit Non-Attributable Report

Source: Medical Mission Debriefs
Topic: Lunar Surface Ops
Issue: Locomotion
Description: "Hopping" on the surface seemed to be the best way to get around with consideration for:
1. Time / distance traveled
2. Energy expenditure

General Comments:
Resolved:
If Resolved how, when, where?
Additional Questions: Can this/should this be practiced prior to arrival?
Summit Topic: Yes

Source: Medical Mission Debriefs
Topic: Lunar Surface Ops
Issue: Waste Management (non-human)
Description: Used food packages, etc. need to be disposed of

General Comments:
Resolved: unknown
If Resolved how, when, where?
Additional Questions: Was any garbage taken from the CM to the LM left on the surface? e.g., Urine bags....Crew described that item would be thrown out per "the plan"
Summit Topic: Yes

<th>Medical Mission Debriefs</th>
</tr>
</thead>
<tbody>
<tr>
<td>Topic:</td>
<td>Lunar Surface Ops</td>
</tr>
<tr>
<td>Issue:</td>
<td>Surface Views</td>
</tr>
</tbody>
</table>
| Description: | View of the surface from the LM window is different than through the visor on the surface itself  
- Looking into the sun toward the horizon was limiting secondary to loss of contrast/resolution  
a. Glare, brightness, etc.  
- Re-directing gaze down from the sun helpful with surface details  
- View in the shadows was good after re-adjustment from the light. However, the light level in the shadow is really low  
a. Comparable to the views in the pictures taken by the crew  
b. Vision in the crater was acceptable  
- Visors were used. Both anterior vision in sunlight and inner vision  
a. Blinder was used on occasion in the run |

</thead>
<tbody>
<tr>
<td>Topic:</td>
<td>Lunar Dust</td>
</tr>
<tr>
<td>Issue:</td>
<td>Exposure Observations</td>
</tr>
<tr>
<td>Description:</td>
<td></td>
</tr>
</tbody>
</table>
  a) Exposure caused nasal congestion, according to CDR and LMP  
  b) Dust floating everywhere in the LM upon return to 0 gravity. This prompted the CDR/LMP to keep their helmets on  
  c) Dust particles got into their eyes causing irritation  
  d) Dust was ubiquitous, prompting the crew on board to box up item in the LM and send across the hatch to the CMP. They functioned with canister closed until transfer to keep the CM clean. |

**General Comments:**

Resolved:

If Resolved how, when, where?

**Additional Questions:**  
What did the crew use to treat eye, nasal irritation?

**Summit Topic:** Yes

</thead>
<tbody>
<tr>
<td>Topic:</td>
<td>Lunar Surface Ops</td>
</tr>
<tr>
<td>Issue:</td>
<td>fatigue</td>
</tr>
<tr>
<td>Description:</td>
<td></td>
</tr>
</tbody>
</table>
  LMP: During EVA the right hand fatigued because of the suit valve (the glove and "pipe tangled up" also unscrewing the core tubes and getting the caps off them was very fatiguing and that arm gave out. Carrying an instrument (lost in dictation) was tiring because it was cumbersome and flopping all around. It was heavy. The flopping of the weights and the longer distance to carry it than in sims made it difficult. |

**General Comments:**

Resolved:

If Resolved how, when, where?

<tr>
<td>Description:</td>
<td>Brightness of the lunar surface caused difficulty with vision. Felt sunglasses were OK, but &quot;you can't operate with sunglasses. &quot;Where you want the shielding is in the window. You want to pick up a pair of binoculars you don't look through sunglasses and do that very well.&quot;</td>
</tr>
<tr>
<td>General vision</td>
<td>Note: the lunar brightness problems discussed here are when using assisted devices which gather light and focus it, increasing the retinal light intensity--binoculars and cameras. This suggests the 'fix' is filters, appropriate for the device, at the optical entrance, and filters at the viewing port as needed to protect the crew's eyes (there has been a retinal injury on the ISS secondary to multiple photography of the sunset with a 35 mm through the lens camera. The eye can gather and focus light sufficiently to multiply the retinal light intensity by 300,000 times the incident intensity.</td>

<td>Illnesses/Injuries</td>
</tr>
<tr>
<td>Issue:</td>
<td>Space Motion Sickness</td>
</tr>
<tr>
<td>Description:</td>
<td>LMP experienced significant SMS during the mission: tumbling sensation, nausea and vomiting, anorexia, his head/neck get out of the suit helmet as in “tumbling my gyros completely”. Vomiting episode. FD3 was not preceded by any parasympathetic cues, i.e., cold sweats, stomach awareness, vertigo. 2nd episode of vomiting occurred 4-4.5 hours after the first episode in the LM. Traveling through the tunnel contributed to this. -Symptoms improved steadily after second episode -Appetite never returned for duration of Mission; Marazine slowly helped decrease symptoms for the first two days. Limiting head movement and moving slowly were keys to preventing dizziness/nausea. However some positions were unavoidable that triggered SMS (i.e., putting heads into suit).</td>
</tr>
<tr>
<td>General Comments:</td>

Apollo Summit Non-Attributable Report

<table>
<thead>
<tr>
<th>Topic:</th>
<th>Illnesses/Injuries</th>
</tr>
</thead>
<tbody>
<tr>
<td>Issue:</td>
<td>Health Concerns</td>
</tr>
</tbody>
</table>
| Description: | a) Lunar dust got in their eyes  
|              |  - Particle cleared on its own – did not require any eye drops  
|              |  b) Took complained of nasal stuffiness throughout the flight. Took Ornade for symptomatic relief  
|              |  c) Crew had no other complaint of illness before, during or after flight  
|              |  d) Crew denied symptom  
|              |  1. Mild loss of appetite 1st 24-48 hours  
|              |  2. Minimized head and body movements  
|              |  e) Crew noticed facial puffiness  
|              |  f) Low back pain  
|              |  1. Bringing knees into fetal position is a position of comfort; Stretching back is no good  
|              |  2. It was hard to make the feeling in CMP back go away  
|              |  3. Crew did not complain of back pain upon return to 1 g  
|              |  g) Dust material had distinctive “wet ashes” or gun powder smell to it  

General Comments:
Resolved:
If Resolved how, when, where?
Additional back Questions: Did the crew describe what exercises or positions improved or exacerbated the pain?
Summit Topic: Yes

Source: BME logs
Topic: Illnesses/Injuries
Issue: stuffy head
Description: "stuffy head" requiring actifed now and before EVA
General Comments:
Resolved:
If Resolved how, when, where?
Additional Questions: Was this secondary illness or space adaptation?
Summit Topic: Yes

<td>Physical Observations</td>
</tr>
<tr>
<td>Description:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>a) Urination, particularly at night was increased during the first few days of the mission</td>
</tr>
<tr>
<td></td>
<td>b) Crew made a conscious effort to drink lots of water on this mission, although this dropped off on the way home</td>
</tr>
</tbody>
</table>
|               | c) Facial fullness, swelling was not noticeable on FD1, but improved "Just like standing on your head"
|               | d) Crew described "coronal discharge" in great detail: flashes in their eyes during the mission, (or streaks of light)
|               | - Noticed less CD if they faced toward the moon than away from it |
|               | - Typically occurred in one eye only |
|               | - Apollo 11 crew described it but it wasn't in the mission debrief |

### General Comments:

Resolved: N/A

If Resolved how, when, where?

Additional Questions:

1. Does coronal discharge pose a problem?
2. What was the average H2O intake per CM per day?

Summit Topic: Yes

<tbody>
<tr>
<td>Topic:</td>
<td>Illnesses/Injuries</td>
</tr>
<tr>
<td>Issue:</td>
<td>Head stuffiness</td>
</tr>
<tr>
<td>Description:</td>
<td>LMP: 3-4 days prior to launch had head stuffiness, worsened during first half day in flight. Blew his nose a lot and used Afrin, which cleared it for 4-8 hours. Didn't think the Afrin spray bottle actually delivered anything in weightlessness. After landing on the moon, his ears did not bother him anymore. But he continued to use Afrin, though he was never symptomatic on the moon.</td>
</tr>
<tr>
<td></td>
<td>CDR: Stuffy the 1st in flight day, was fine during the first EVA, but back in the LM &quot;I always have sinus trouble anyhow&quot; Felt his nasal stuffiness after the 1st EVA was secondary to &quot;dirt.&quot; When pressurizing his suit for second EVA had difficulty clearing his left ear. Subsequently his left sinuses and ears &quot;had mucous&quot; which he attributed to lunar dust. Felt he was getting a cold &quot;the morning that we got up from coming back from the moon.&quot; The second day he had other symptoms of a 'cold,' headache, myalgia.</td>
</tr>
<tr>
<td></td>
<td>CDR: noted he had a lot of dust exposure after returning to the LM, and docked with the CM and transferred gear, etc. &quot;The cabin was so full of junk floating around in Zero G, I took off my helmet and I really blinded myself. I had cinders in my eyes, and that stuff was all over everywhere.&quot; I told LMP not to take his helmet off.&quot; Positive flow kept all of that stuff out of the command module.&quot;</td>
</tr>
<tr>
<td></td>
<td>CDR: we kept the hatch closed. &quot;I'd just pack one box in the proper bag, I'd open the hatch, and I'd throw it to Dick. He'd give me the LiOH and we'd replace that, and I'd leave the hatch closed.&quot; this helped keep the CM clean. Removed suits in the LM and passed them across for stowage in the &quot;L-shaped bag &quot;because they were so damn dirty.&quot;</td>

</tr>
</thead>
<tbody>
<tr>
<td>Topic:</td>
<td>Illnesses/Injuries</td>
</tr>
<tr>
<td>Issue:</td>
<td>Flashes in visual field</td>
</tr>
</tbody>
</table>
| Description: | Crew saw flashes, as dots or flashes or streaks, CMP also saw them while asleep!?
|                            | Detailed description: "like a distant lightning flash in a cloud. It would sort of fill the whole eye. The bright dots were just that -bright while dots, some with halos and some without. The streaks were either pencil thin, clears freaks or fuzzy that went to think and then fuzzed out again." Moving in all different directions and they seemed to be randomly approaching. "The bright dots, you had the impression that they were coming at you..... the flashbulb type, it looked like what I'd call -the bright dots looks like a flashbulb going off. It's like the retinal photography except not quite that bright."
|                            | It looked like a cloud particle chamber where you see these things shooting through there. I had the feeling that the things were in the eye (LMP and CDR). CMP did not see them -possibly because of different shielding. Very brief, no after-effect, no color. Dots were very bright, very brief. |

**General Comments:** ALF MED - Apollo Light Flash Moving Emulsion Detector --apparently worn by the astronaut. Didn't fit LMP well.

**Resolved:**

**If Resolved how, when, where?**

**Additional Questions:**

**Summit Topic:** No

Source: Flight Surgeon logs
Topic: Bioinstrumentation
Issue: no cabin leak rate
Description: no cabin leak rate data available

General Comments:
Resolved:
if Resolved how, when, where?
Additional Questions: How are we preparing to limit loss of data feeds?
What are our "acceptable limits" of lost data?

Summit Topic: No

Source: BME logs
Topic: Bioinstrumentation
Issue: Biomed probs
Description: EKG lost, EECOM thinks this whole stateside pass is a “Fiasco” and really had been “Screwed up” in several areas

General Comments:
Resolved:
If Resolved how, when, where?
Additional Questions: How was biomed problems worse on the statsid pass?

Summit Topic: No

Source: Flight Surgeon logs
Topic: Bioinstrumentation
Issue: sleep station hardware not functioning
Description: hardware not functioning in sleepstation so FS unable to identify if crew asleep

General Comments:
Resolved:
If Resolved how, when, where?
Additional Questions: Would we be able to have wireless monitoring so this would not be a problem?
We could have back up wire?
Appendix A
Apollo Summit Non-Attributable Report

Summit Topic: No.
Source: Flight Surgeon logs
Topic: Bioinstrumentation
Issue: PCO2 sensor malfunction
Description: PCO2 sensor read 1.0 @ launch therefore FS considers this a bias of 1=0
General Comments: Repeated malfunction of carbon dioxide sensor device
Resolved: No
If Resolved how, when, where?
Additional Questions: Do we need back up PCO2 detector?
Summit Topic: Yes

Source: Flight Surgeon logs
Topic: Bioinstrumentation
Issue: Faulty biomed sensor and leads
Description: LMP Biomed leads with bad connector at 2 and broken lead in 3
General Comments:
Resolved:
If Resolved how, when, where?
Additional Questions: Are these problems that are noticed on ISS and Shuttle?
Summit Topic: No

Source: Flight Surgeon logs
Topic: Bioinstrumentation
Issue: Sensor discomfort
Description: The Sensors are drying out. Itching and discomfort under the sensors
General Comments:
Resolved:
If Resolved how, when, where?
Additional Questions: What options of application material do we have for sensors?
Appendix A
Apollo Summit Non-Attributable Report

Summit Topic: No
Source: Flight Surgeon logs
Topic: Bioinstrumentation
Issue: PRD
Description: CMP stated PRD was all fogged up
General Comments:
Resolved:
If Resolved-how, when, where?
Additional Questions: Will we have back up PRD in case one doesn't work? Explain what caused this?
Summit Topic: Yes

Source: Medical Mission Debriefs
Topic: Bioinstrumentation
Issue: Electrode Observations
Description: a) Crew had problems with electrode paste drying cut around FD7-9. Result was itchy and irritations b) Crew felt the mess and set-up with changing the electrodes/apply new paste was more trouble than it was worth
General Comments: Recommend removing the electrodes for one day then re-applying in a staggered fashion.
Resolved:
If Resolved-how, when, where?
Additional Questions: Is it desirable to change the electrodes out every day or every other day? Will frequent changing of electrodes cause similar skin problems
Summit Topic: No

Source: BME logs
Topic: Bioinstrumentation
Issue: Antenna problem
Description: Antenna problem cause of loss of signal of biomed
General Comments:
Resolved:
If Resolved-how, when, where?
Additional Questions: Will we still have antennas on the CEV?
Summit Topic:
### Source: Flight Surgeon logs
- **Topic:** Bioinstrumentation
- **Issue:** Biomed problems
- **Description:** Problems with Biomed and PCO2 sensor problems
- **General Comments:**
  - **Resolved:** No
  - **If Resolved how, when, where?**
- **Additional Questions:**
  - **Summit Topic:** Yes

### Source: Medical Mission Debriefs
- **Topic:** Bioinstrumentation
- **Issue:** Sensor Observations
- **Description:**
  1. Sensor were irritating, caused backlog. Particularly once the crew took them off approximately FD4
  2. Biomed ECG data was good throughout the mission
  3. Crew does not appreciate daily server changes. Takes too much time
- **General Comments:**
  - **Resolved:**
  - **If Resolved how, when, where?**
- **Additional Questions:**
  - Are 4 sensors necessary? Can ECG and requests info be obtained with 2 or 3 e.g., Split electrodes (Gemini)?
  - **Summit Topic:** No

### Source: BME logs
- **Topic:** Bioinstrumentation
- **Issue:** O2 flow meter
- **Description:** O2 flow meter pegged full scale high
- **General Comments:**
  - no more mention or explanation of this event
- **Resolved:**
- **If Resolved how, when, where?**
- **Additional Questions:**
  - Was this not considered serious or is this within normal limits? Why no more mention of this?
  - **Summit Topic:** No
  - **Source:** BME logs

Source: Medical Mission Debriefs
Appendix A
Apollo Summit Non-Attributable Report

Topic: Bioinstrumentation
Issue: ZPN (respiration) electrode
Description: ZPN signal derived via an impedance measurement. The electrode, applied in a 14.7 psia atmosphere failed with depressurization to 5.0 psia. The electrode was removed and expanded gas removed from the sensor pad with manual pressure and the electrode re-applied and it functioned well after that.

General Comments:
Resolved:
If Resolved how, when, where?
Additional Questions:
Summit Topic: No

Source: Medical Mission Debriefs
Topic: Bioinstrumentation
Issue: don-doff time required
Description: 10-15 minutes. Could save 10 minutes of the time by packaging the sponges to avoid having to cut six open to use five, and making the little sponges somewhat larger than the holes.
Berry replies they will take “some lotion to do this?”
Entire crew suggested a ‘work station’ for storage after doffing, and to assist next donning of the electrode harness
Electrodes caused skin irritation

General Comments:
Resolved:
If Resolved how, when, where?
Additional Questions:
Summit Topic: Yes

### Bioinstrumentation

**Source:** Medical Mission Debriefs  
**Topic:** Bioinstrumentation  
**Issue:** Sensors and leads  
**Description:** Suggested a monitoring check before securing for sleep, so they don't get awakened to fix a pre-existing problem. Electrodes were modified after Apollo 15 to reduce skin irritation, but the process of applying and removing electrodes was so time-consuming some crew preferred to just leave them in place between monitoring sessions. Itching was a problem and the itching interfered with sleeping for the CMP. Tape was a problem for some. The allotted timeline of 2 minutes to don and doff biomedical sensors usually required about 20 minutes.  
**General Comments:** CMP did not think the monitoring was justified, useful, or a good use of lunar mission time. Dr. Berry states: “I guess the first thing I'd like to say is that I am totally amazed, after 10 trips of manned space flight, at the total lack of understanding that you guys seem to have about why we did some of the things that we did.” Followed with a length, detailed explanation of considerations other than 'operational' that influence biomedical activities.

**Resolved:**
**If Resolved**
**how, when, where?**

**Additional Questions:**

**Summit Topic:** No

---

**Source:** BME logs  
**Topic:** Bioinstrumentation  
**Issue:** applying J and J cream  
**Description:** applying sensors states sensors may not stick well due to application of J and J cream  
**General Comments:**

**Resolved:**
**If Resolved**
**how, when, where?**

**Additional Questions:**

**Summit Topic:** No

Appendix A
Apollo Summit Non-Attributable Report

Summit Topic: No
Source: Flight Surgeon logs
Topic: Bioinstrumentation
Issue: skin cream
Description: skin cream cleared up old sensor site

General Comments:
Resolved:
If Resolved how, when, where?
Additional Questions:
Summit Topic: Yes

Source: Medical Mission Debriefs
Topic: Bioinstrumentation
Issue: electrode drying
Description: biological electrodes dried out after about 12 hours. LMP recommended new electrolyte and procedures as the current system is unsatisfactory from both a skin irritation and a maintenance standpoint. Removal of the electrode revealed a brown scab underneath and no electrolyte paste. Skin electrodes in the CM were different from those in the LM.

General Comments:
Resolved:
If Resolved how, when, where?
Additional Questions:
Summit Topic: No
Appendix A
Apollo Summit Non-Attributable Report

Source: Medical Mission Debriefs
Topic: Medication/ Medical Kits
Issue: Use & Amount Dispensed
Description:

a) Actifed for runny nose - threshold secretions (8)
b) Aspirin for general principles? (6-8)
c) Marezine for nausea - primary (BIG); secondary (prevention)
d) Dulcolax taken before flight
e) Dexedrine (1 dose) FD7 or so with minimal effect
f) Lomotil (2-3 doses) to intentionally delay BM after launch and during flight. However, crew only felt it "quieted the stomach down" by approximately 8 hours
g) Darvon (2)
h) Nasal emollient?

General Comments:
BME log 58:00:xx 6 Actifed consumed, leaving 18 tabs for remaining mission

Resolved:

If Resolved how, when, where?

Additional Questions: How did kit arrangement, allotment of medications impact crew during the mission?

Summit Topic: Yes

Source: Medical Mission Debriefs
Topic: Medication/ Medical Kit
Issue: Use and Amount Dispensed
Description:

a) 24 tabs Actifed
b) 24 tabs antibiotic (urinary class) (See General Comments)

General Comments:
Use of antibiotics. Flight Surgeon log – Symptoms treated only when definite evidence of purulence and increased temp, then begin antibiotics

Resolved:

If Resolved how, when, where?

Additional Questions:

Summit Topic: Yes
Source: Medical Mission Debriefs
Topic: Medication/ Medical Kit
Issue: Use & Amount Dispensed
Description:
   a) Lomotil (2) for stomach upset
   b) Seconal 100 mg, 150 mg X 1
   c) ASA (6)
   d) Meclizine (Marezine)
General Comments:
   Seconal left CM with bad headache
Resolved:
If Resolved how, when, where?
Additional Questions: Medication side effects
Summit Topic: Yes

Source: Medical Mission Debriefs
Topic: Medication/ Medical Kit
Issue: Observations
Description:
   a) 2 kits: difficult keeping track of item in first and second kit
   b) Eye drops, nasal emollient, hand cream was used
   c) Need chapstick; however, real chapstick cannot used in a high O2 environment
   d) Wet wipe for bathing had a putrid odor
General Comments:
Resolved: No
If Resolved how, when, where?
Additional Questions:
Summit Topic: Yes

### Source: Medical Mission Debriefs
### Topic: Medication/ Medical Kit
### Issue: Crew Observations
### Description:
- a) Nose drops packed at 15 psi basically exploded in medical kit at 5.0 psi, same for the nose emollient. Big mess
- b) The blister packs that the MEs were stored in also expanded/cracked. The seconal caps welled like a balloon and pulled apart, sending tiny flakes all over the cabin.

**General**
- b) Recommendations: Pack all MEs in vacuum.

### Comments:
### Resolved: No
### If Resolved how, when, where?
### Additional Questions:
### Summit Topic: Yes

---

### Source: BME logs
### Topic: Medications
### Issue: stomach rumbling
### Description: Lomotil taken to calm stomach secondary to H2 ingestion
### General
- Note the significant trickle down effect of gas in water, lomotil taken to quiet stomach, which could change normal bowel habits. This also leads to possible dehydration leads to multiple things including decreased performance, etc.

### Resolved:
### If Resolved how, when, where?
### Additional Questions: Did this cause change in normal bowel habits?
### Summit Topic: Yes

| Description: | a) Lomotil to prevent BM night (11 before landing and night before LM activity (2)  
b) ASA was taken each night (2) for headaches and to help with sleep  
c) Crew felt they did not want to report medication usage or their problems because they did not want anyone to know about it (lack of PMC)  
d) Crew felt that the following medication should be taken by the crew when the crew feels and not required any radio comm with ground |
|          | Afrin  
|          | Lomotil  
|          | ASA  
|          | Dexedrine |
| General Comments: | |
| Resolved: | |
| If Resolved how, when, where? | |
| Additional Questions: | Has the PMC arrangement with crew and FS ameliorated this concern?  
Should the use of lomotil prophalactically so as not to be bothered during landing be a concern? Do we need to develop another plan to assure crew? |
| Summit Topic: | Yes |

| Description: | a) Afrin solution leaked from bottle, similar to previous crew experience  
-Crew tried absorbing solution onto cotton ball and sniff to deliver medication to nasal mucosa, but this did not work too well  
b) Actifed used for nasal congestion  
c) Sleeping pills were taken first couple of days after notifying the ground  
-LMP would sleep approximately 5 hours, get up take one, sleep another 3-4 hours  
d) Crew bothered about the lack of confidentiality to take and repeat medication use |
| General Comments: | |

</tr>
<tr>
<td>Issue:</td>
<td>privacy</td>
</tr>
</tbody>
</table>
| Description:     | LMP: "... one of our big problems; if we take a goddamned aspirin up there, it becomes an international incident. We object strenuously to it."
|                  | CMP: "Especially this flight crew, just flat-ass object to this type of thing. Now if we can convert, and be able to talk to you like we can right now privately, without the Jim Malone's or the Bill Heinz's (two news reporters) or the rest of the world in on this god damned act, we'd do it. But I'll be god damned if I wasn't damn reluctant to come up and say, I don't know why, maybe this is just a personal thing with me, but I'm sure a lot of the other guys feel the same way."
|                  | CMP: "Get in the posture where these things aren't flags as a god damned potential space problem and saying you ought not to be there because you got a headache... then I think we would feel more free to talk about it." Quotes included to convey the depth of feeling of crew on this point.|
|                  | CDR: Strongly argued for private conversations when the crew requests it. Dr. Berry strongly concurred with the importance of crew being able to talk with ground without unconstrained access to the rest of the world to the conversation. |
| General Comments:|                                                       |

Source: Medical Mission Debriefs
Topic: Medications
Issue: Nose drops
Description: LMP: 1 drop in each nostril worked for 10-12 hours, for nasal stuffiness. CDR: nose drops helped with the mucous but not the overall fullness sensation CMP thinks he used too much 3 hours prior to reentry, with eye tearing and sensation in his sinuses. Didn’t notice any tachycardia with its use.
General Comments: No ear problems at all. Cleared well with pressure changes.

Source: Medical Mission Debriefs
Topic: Medications
Issue: cardiac
Description: apparently a Seconal was prescribed and the CMP states “except your intent was purely to have some medication to the heart.” To which Dr. Berry answered “Right.” Then the CMP says “That was the idea behind it. And that was the only thing on board which did apply to the heart.” To which Dr. Berry answered “That’s right.”
General Comments: Unable to decipher what the real message was.
Source: Medical Mission Debriefs
Topic: Medications
Issue: Potassium
Description: Concern that potassium powder were contributing to the frequency of bowel movements and loose stools. "We're overdoing it" with regards to going to the bathroom enough. "The fact is it was unbelievable, abdominal bloating, 'gas pains" and flatus were also a problem. The odor was "terrible."

General crew Comments: Bowel movements were sources of difficult hygienic collection and stowage and preferred to minimize them.
Resolved: No
If Resolved how, when, where?
Additional Questions:
Summit Topic: Yes

Source: Medical Mission Debriefs
Topic: Medications
Issue: Seconal use
Description: CMD took two seconal, which were the only use of that during the flight. CDR took biomeds, including ASA. General purpose topical skin cream was only other med used.

General Comments: Seconal was very sedative which was a very undesirable side effect.
Resolved: 
If Resolved how, when, where?
Additional Questions:

Appendix A
Apollo Summit Non-Attributable Report

Additional Questions: How should we or should we approach waste/garbage storage especially in light of longer exploration missions? How often was this a problem?

Summit Topic: Yes
| Source: | Flight Surgeon logs |
| Topic: | Environmental |
| Issue: | Chlorination of water |
| Description: | Confusion on rather to open inlet or not during chlorination. Therefore got a slug of Very chlorinated water |

**General Comments:**

**Resolved:**

**If Resolved how, when, where?**

**Additional Questions:** Rather we use chlorine or iodine we should have it brutally simple on how and when to use?

**Summit Topic:** Yes

| Source: | Flight Surgeon logs |
| Topic: | Environmental |
| Issue: | trash storage |
| Description: | Concerns of trash storage problems |

**General Comments:**

**Resolved:**

**If Resolved how, when, where?**

**Additional Questions:** How do we currently take care of trash, how is this different than what was used with Apollo?

**Summit Topic:** No

| Source: | Flight Surgeon logs |
| Topic: | Environmental |
| Issue: | coughing from fiberglass snow in CM |
| Description: | coughing from fiberglass snow in CM |

**General Comments:**

**Resolved:**

**If Resolved how, when, where?**

**Additional Questions:** Could this happen again? Dose this pose a current problem?
Summit Topic: Yes
## Source
Flight Surgeon logs

## Topic
Environmental

## Issue
Thruster awakens CMP

## Description
CMP awakens each time thruster fires

### General
Sleep was sporadic and frequently interrupted

### Resolved:

### Additional Questions:
Will our countermeasures for Comm interrupting sleep also help with Thruster interruptions?

### Summit Topic:
Yes

---

Flight Surgeon logs

## Topic
Environmental

## Issue
fiberglass snowstorm

## Description:
"Snow storm of insulation material is in LM "Snow in CSM also" Like Fiberglass"

### General

### Resolved:

### Additional Questions:
Where did this fiberglass come from?

### Summit Topic:
Yes
Appendix A
Apollo Summit Non-Attributable Report

Source: Medical Mission Debriefs
Topic: Environmental
Issue: Space Craft Issues
Description:
a) Water chlorination process is to be done within 12 hours of launch, if the crew launches on time. The chlorine valve is left closed from launch. Chlorine applied to the systems lasts 12 hours; however, the crew had not used the system, which extended > 12 hours.
b) Bubbles found in the water bag likely because O2 gas diffused across the bladder. The problem was fixed by de-aerating the water before launch in the bladder.
c) Rested good according to crew.
d) Crew started out drinking approximately 3 lbs of water per day. Gradually this was increased to normal range of 7-7.5 lbs per day.
e) Hot water had more gas in it than the cold water.
f) Waste management reported that it was a "mess"

General Comments:
a) Make sure you chlorinate with the valve open, otherwise, very light level of chlorine in water. Need to pay particular attention to this in the event of delayed launch.
b) Crew was upset by the presence of gas in the water system because it was passed into the stomach creating fullness and flatulence. Preventing eating.
c) Urine output was twice a day secondary to low oral water intake according to crew. However, volume was considerable filling urine tank with each void.
d) Urine collection was dumped overboard. Crew reported they opened the dump valve before voiding. The suction created was not strong enough.
e) The urine bag, if used, caused back pressure.
f) CDR suggested designing a diaphragm at an angle to prevent back splash.
g) Crew was very concerned about voiding ability during time-critical OPS the amount of time it took to get set-up for a voiding dump.

Resolved: Yes- gas bubbles in water system

if Resolved - how, when, where?

Additional Questions:
a) Is it necessary to chlorinate the system if it hasn’t been used yet?
b) What about fuel cell water? Was this a problem?
c) What is Ammonia, germicide, fungicide, detergent and deodorant used in?

Summit Topic: Yes

</table>
Source: Medical Mission Debriefs
Topic: Personal Hygiene/ Environment
Issue: Urine collection system
Description: p.25: LMP: The urine and feces collection systems are lousy. The odors inside the cockpit are quite bothersome. No good way to wash after a BM. Need some atmosphere control. "I think the gases in the hydrogen and the water just circulate through your system so you end up passing a tremendous amount of volume of gas in there." Fixing these areas would "make it a lot more livable." CDR: We have vacuum outside that could be used with a well-designed urinal.

General Comments: In general, the WCS was broken.
Resolved: No
If Resolved how, when, where?

Additional Questions:
Summit Topic: Yes

Source: Medical Mission Debriefs
Topic: Environmental
Issue: Waste Management
Description: a) BM's were reported by crew -approximately 2 per CM during the mission
b) Crews performed house cleaning in two ways:
   1. Took hose blowing air out and directed dust toward the accumulation system
   2. Cleaned filter screen
c) CDR got thirsty during mission –drank a lot of water. Tried to avoid beverages as they were too sweet
d) No problems with urination ( from physiological standpoint)
e) Urine and feces collection system is lousy. Crew would prefer no bag at all
f) Odors in cabin were awful -SOLUTION: Circulate cabin gasses
g) Shaving was cumbersome. Could not get your face wet enough
h) Improved wet wipes, preferred soap

General Comments:
Resolved:
If Resolved how, when, where?
Additional Questions: Crew describes something floating in cabin during conversation of BM frequency. What were they talking about? Dust vs.?
Summit Topic: Yes

</thead>
<tbody>
<tr>
<td>Topic</td>
<td>Environmental</td>
</tr>
<tr>
<td>Issue</td>
<td>In-suit urine collection</td>
</tr>
<tr>
<td>Description</td>
<td>Urine drain line kinked “apparently” all the time.</td>
</tr>
</tbody>
</table>

**General Comments:**

**Resolved:**

**If Resolved**

**how, when, where?**

**Additional Questions:**

**Summit Topic:** No

---

<table>
<thead>
<tr>
<th>Source</th>
<th>Medical Mission Debriefs</th>
</tr>
</thead>
<tbody>
<tr>
<td>Topic</td>
<td>Environmental</td>
</tr>
<tr>
<td>Issue</td>
<td>Visual flashes</td>
</tr>
<tr>
<td>Description</td>
<td>LMP: very sharp flashes, straight,... instantaneously...</td>
</tr>
<tr>
<td></td>
<td>CDR: “The single streak and the double shot appeared to be very clear to me.”</td>
</tr>
<tr>
<td></td>
<td>CMP: “quite clear...most of my streaks appeared to be on the periphery...”</td>
</tr>
<tr>
<td></td>
<td>CDR: “...side, from left to right. &quot;generally random&quot;”</td>
</tr>
<tr>
<td></td>
<td>LMP: couldn't really correlate a pattern out of it.</td>
</tr>
<tr>
<td></td>
<td>LMP: a couple looked like lightning in a cloud</td>
</tr>
</tbody>
</table>

**General Comments:**

Some flashes were streaks, some were pinpoint, some were larger 'blobs' During a test period, some eyes were open, some closed. LMP described 18, CDR had 14 and CMP had 8 visual flashes

On three occasions two persons reported a flash simultaneously

After very bright (“nova or super nova”) flashes a 'halo' effect was described

Crew described the flashes as 'definitely' in their eyeball, not in the cabin.

CDR: no preferred orientation of flash

**Resolved:**

**If Resolved**

**how, when, where?**

**Additional Questions:**

**Summit Topic:** No

Summit Topic: Yes

<table>
<thead>
<tr>
<th>Source:</th>
<th>Medical Mission Debriefs</th>
</tr>
</thead>
<tbody>
<tr>
<td>Topic:</td>
<td>Environmental</td>
</tr>
<tr>
<td>Issue:</td>
<td>water bags</td>
</tr>
<tr>
<td>Description:</td>
<td>There were air bubbles in the water which also changed the water taste. Crew estimated 20-30% of bag volume was air. Far more gas in hot water than cold water. Juice bags were not filled every time, estimated water gun strokes were used to add water to juice bags. Water gun was not consistent, difficult. Filling the bag up before you can drink was operationally involvement and particularly not useful at night. Had to drink the entire bag once you started - no wetting your mouth or partial drinks per thirst level</td>
</tr>
</tbody>
</table>

**General Comments:**

Resolved: No

If Resolved how, when, where?

Additional Questions:

Summit Topic: Yes
**Source:** Medical Mission Debriefs  
**Topic:** Environmental  
**Issue:** urine collection  
**Description:** New procedures which crew felt were incorrect, could not be discussed because there was no private communication and “you can’t discuss these things in a rational manner. You have to do them. Although that was a dumb procedure.

**General Comments:**

**Resolved:**

**If Resolved how, when, where?**

**Additional Questions:**

**Summit Topic:** No

---

**Source:** Medical Mission Debriefs  
**Topic:** Environmental  
**Issue:** new fecal bags  
**Description:** "We’d like to go back to the old ones and take the finger out.” Not clear what that means.

Fecal bags were returned to earth. They were not gas-tight and were completely filled. Concerned about bags bursting during EVA. Not compatible with an operational mission. Is there any justification for it? Consider the health hazard if a bag bursts. "You'll never get that place cleaned up, never.”

You could jettison them during an EVA. "Unfortunately, there is only one bag," so you can't throw it away.

**General Comments:**

**Resolved:**

**If Resolved how, when, where?**

**Additional Questions:**

**Summit Topic:** Yes

<tr>
<td>Description:</td>
<td></td>
</tr>
</tbody>
</table>
  a) Sleep was fitful for the first three nights and last night before re-entry  
  b) Daily cycle shifting for upcoming events (rendezvous, burn, etc.) made sleeping on schedule difficult  
  c) Bring ear plugs, Blinders during sleep shift. Also consider having all three CM sleep at same time, or 2 CM sleep and one CM minding the store  
  d) CM went through 5 days with 4-5 hours sleep, felt fatigued throughout the mission:  
    e) "Timeline was terrible". Careful review of the flight plan reveals that the crew was working twelve days in a ten day mission  
    f) Crew slept between 5-7 hours per work day at best  

| General Comments: | |
| If Resolved how, when, where? | |
| Additional |  
  1. Sleep cycle shifting?  
  2. Do the astronauts need to get used to sleeping with ear plugs and Blinders before leaving? If so how long |
| Questions: | |
| Summit Topic: | Yes |

</table>
| Description:     | a) Crewmember did not feel the pre-flight sleep period was long enough - was sleepy on launch  
b) Work / rest cycle could be improved  
c) Sleep cycle / deprivation affected the crew performance - Average 2 hours continuous sleep (see General Comments and Additional Questions)  
d) Crew preferred being wedged into something to feel secure for sleep  
Sleep restraint device was outstanding |
| General Comments:| Work / Rest Cycle Suggestions: Simultaneous sleep cycle during landing phase  
1. Window cover ups  
2. Turn out lights  
3. 2 CM in sleep restraint and one asleep with headset on - Ground would not call up except impending gimbal lock or other emergency  
4. Ground automatically switch all 4 OMNI antennas |
| Resolved:        | Another crewmember gives a good description of the sleep cycle |
| If Resolved how, when, where?: |                                  |
| Additional Questions: | How can work/rest cycle be specifically improved?  
How was crew performance affected by sleep deprivation |
| Summit Topic:    | Yes                              |

Appendix A
Apollo Summit Non-Attributable Report

Source: Medical Mission Debriefs
Topic: Work/Rest Schedule
Issue: Sleep, Work & Rest Observations
Description:

a) Crew slept a lot, between 7-10 hours, but described it as a "light sleep. Typically woke early at least 1 hour before schedule
b) LMP would sleep 5 hours, take a sleeper then return to sleep for 3.4 hours
c) Reverse Schedule - crew extended FD1 as long as possible to adjust to reversed day-night flight plan
d) Scheduled 10 hour sleep period were more than adequate
e) Work days were typically 14-15 hours
f) Crew suggests not eating dinner before going to bed. Apparently that is how meals were scheduled in the flight plan
g) Crew felt the work/rest was reasonable, allowed them to accomplish what they needed and rested
h) On the lunar surface, sleep/rest is a minor issue, The busy pace and minimal rest did not effect their limit of efficiency. However, this would become an issue with extended-duration ops.
i) Sleep in the LM on the Lunar Surface was okay.

General Comments:
Resolved:
If Resolved how, when, where?
Additional Questions: Did you think you could function/sleep in the LM for > ? days on the lunar surface? Crew seemed to think so
Summit Topic: Yes

Source: Medical Mission Debriefs
Topic: Work/Rest Schedule
Issue: Sleep
Description: CMP: slept best with the couch flat, in the sleeping bag (it got cold at night) and pull the straps down. LMP: usually slept 5 hours at end of day, wake up, take a sleeping pill. Without the pill, didn't get back to sleep --thinking about the flight
CMP: Difficulty sleeping on first night, back uncomfortable. CDR: Had no back pain during flight, but for about 4 days post-flight, in the Mobile Quarantine Facility (MQF) was hobbling, secondary to back pain.

General Comments: Several CM had back pain during their mission.
Resolved: No
If Resolved how, when, where?
Additional Questions: What in-flight activities relieved back pain severity?
Summit Topic: Yes

### Source: Medical Mission Debriefs
### Topic: Physiological Function
### Issue: Sunglasses
#### Description:
CDR had a headache during first couple of revs in lunar orbit which he attributed to moon gazing. "You need to protect your eyes." Dr. Berry points out the sunglasses are USAF issue N-15 type, neutral density filter, 15% transmission. These have plastic lenses, USAF have glass lenses. While on lunar EVA, this was not a problem. Crew did not agree that the sample N-15 sunglasses presented at the debrief were the same as what they flew with.

### General Comments:

---

### Source: Medical Mission Debriefs
### Topic: Physiological Function
### Issue: Vision on the lunar surface
#### Description:
Can see very well-particularly cross-sun. Not much contrast over large distances, difficult to discern horizon sometimes. Very bright looking into the sun, lots of glare. Initially going into a shadow it takes about 15 seconds for vision to accommodate, after that accommodation improves, but out of the shadow is so bright LMP doubts full reduced lighting accommodation occurred. Could see into craters "pretty well." Intermittently used the outer visor, used mostly when looking into the direction of the sun. No particular problems expressed.

<tr>
<td>Issue:</td>
<td>Post Flight Quarantine</td>
</tr>
</tbody>
</table>
| Description:    | a) Pre-flight exposure to illness is critical to post-flight condition to ensure that any post-flight illness was not due to lunar exposure  
b) It is critical in the preflight period to allow the crew to slow down in the schedule so as not to lower their resistance to infection,  
c) It will be difficult to ascertain if either this was some latent infection, pre-flight exposure, or lunar exposure |

General Comments: |

Resolved: |

If Resolved how, when, where? |

Additional Questions:  Should pre-flight quarantine be longer than current 7 days on a longer mission?  Should this be 21 days instead? If it should be longer, should crew be quarantined with family to help with mental downside to isolation? If so, should family be removed from quarantine 1 week prior to so crew can mentally prepare |

Summit Topic: Yes |

<tr>
<td>Issue:</td>
<td>Crew Health and Performance</td>
</tr>
</tbody>
</table>
| Description:    | a) During DF 0-2, and last 3 days, coming home the crew kept occupied. But in between they felt they had nothing to do.  
- Wish they had brought recreation materials along: Books, music  
b) CMP felt that he was responsible for the state the ship during the transit time; that the activity was his and LMP could relax during the transit, but he was always on task  
c) CMF was concerned by the flight plan change after the Lunar landing had a CM been at the end of his work day – and he was very tired. Probably not a good idea.  
d) Crew recommended doing something to keep the CMP occupied  
- Comm helps tremendously, especially briefs on every events  
- MSFN relay was the best thing CMP had  
- Crew Suggest for long duration mission wake the SC environment as normal as it is down on Earth (similar to F. Hansen's experience) |

General Comments: Crew health and performance issues during TLC and TEC are key issues for all missions to consider. |

Resolved: No |

If Resolved how, when, where? |

Additional Questions: How do you help the crew mentally and physically prepare for 20-24 hour work days? |
Appendix A
Apollo Summit Non-Attributable Report

Summit Topic:  Yes

Source:  Medical Mission Debriefs
Topic:  Human Factors
Issue:  Lunar Surface Operations, Mission Ops
Description:  Crewmember Observations from debriefs

1. Mission objective was to make contact with Surveyor spacecraft launched approximately February 1967 -need to demonstrate ability to land at a chosen destination
2. "Leadership" was what enabled the Apollo team to accomplish its goals.
3. NASA should let people know that space travel is a dangerous business. When you are at the Earth's edge of technology, exploration is a dangerous business i.e., Magellan started with 240 males and 3 ships; they returned 3 years later with 26 males. Magellan was killed in the Philippines
150 people die/day in auto accident. No one stops driving their car
4. Space suit worked well with the exception of the glove, lack of waist mobility.
5. First few moments after stepping on the moon, make sure you hold onto the handrail for balance. The first couple of moments are pretty wobbly. It takes 3 minutes
6. Look ahead at the ground to be able to visualize craters and boulders. Otherwise, it is possible to trip on a rock. You cannot visualize your feet in the helmet.
7. Rocks existed under the surface dust. easy to trip and fall. The surface is not uniform
8. Lunar Resources Apollo 12 Preliminary Surface Report
   Crew observations and experiments
   -Apollo 12 technical report debrief
   -Give Kranz book
   -Neil Armstrong book
*Confidence comes from reading these reports.
9. Do not re-design lunar tools. They worked for the jobs that had to be performed
10. Hand got tired early from picking up rocks. Re-design gloves.
11. Lunar dust is like ground down lead. Similar to the grindings in a pencil sharpener.
   -"tenacious" made zipper sticky
12. Suit cooled off quickly, efficiently
13. Moon is not magnetic - compass would not work. Never had a gyroscope navigation system
14. Support from the space program will come from appealing to middle - America e.g., Al Shephard hitting the golf ball; Scott dropping banana and feathers to demonstrate Galileo's principles
* Do things on the moon that connect and are of interest to folks on the Earth
15. Volume of the LM was never a problem
16. Don’t solve problems that aren't really problems, e.g. lunar boots
17. No health related issues with the Lunar dust
18. Lighting in the SC was adequate
19. Earthlight was noticeable, a pretty blue
20. Rover did not have headlamp and shouldn't
   -Going into a dark crater a shadow is a bad idea
21. Apollo 12 did not have any contingency plan for a SPE on the surface
22. Exercise countermeasures capability for short moon (1/6 g) should be limited
23. Being a good team member is appreciated/admire the other team members (Pete Conrad)

General Comments:
Resolved:
If Resolved how, when, where?
### Additional Questions

1. Are suits designed to withstand inevitable falls? Is there a backup safety device to the suit in case of falls that may harm suit?  
2. Would packs be useful on lunar surface, would they improve hopping or slow it down?

### Summit Topic

Yes

### Source

Medical

### Topic

Human Factors

### Issue

Isolation of CMP during Lunar Ops phase

### Description

CMP: “You know, it's not too far removed from the prison camp environment. You're stuck up there alone and you're by yourself, you sit and contemplate your own damn misery, and you're out there so damn far away from everything else it could have conceivably been a problem.”

CDR: “These CMP fellows on 28-day missions and things like that are really going to need that recreation. I never pushed for it when I was working CMP, but, boy, right now I'd be in there hustling to get some good music and good tape recorders and some books...that 28 days is going to be a long, long time.”

CDR: “..the happiest I saw CMP in a long time was the day we got back up to the command module. We got in that...and closed the door and he was so happy, he was dancing and jumping around,”

CMP: “It was amazing to me, I was really happy.”

### General Comments

Resolved:

If Resolved how, when, where?

Additional Questions: How can the environment be improved within the vehicle limitation for mass and volume?

Summit Topic: Yes

Appendix A
Apollo Summit Non-Attributable Report

Source: Medical Mission Debriefs
Topic: Human Factors
Issue: circadian shift after launch
Description: LMP: Felt staying up as long as possible the first flight day helped do the diurnal reversal. Ten hour sleep periods were more than adequate -used some of the time the chat in the evenings, do housekeeping functions, etc. Working hours were long.

CDR: Lost track of all Earth time." Got on our own cycle." They were motivated to work on the lunar surface after all the work and training that preceded the actual mission. Didn't want to spend lunar time sleeping.

LMP: during lunar stay, sleep was impaired by the discomfort of the suit --should sleep without the suit.

CMP: was very tired the first night in orbit because of the long day, which was close to 24 hours.

LMP: "... I think you ought to get the guys out of the suit, and you ought to give them a man's blanket, if that Beta cloth Mickey Mouse thing they killed us with, if I'd have slept in that it wouldn't have worked, but if you gave a guy a good roll blanket I couldn't've really slept in that LM if I hadn't been so uncomfortable in my suit." "I'm sure that I would have slept a good 7 hours had I not been uncomfortable in the suit..., if it hadn't been screwed to my shoulders like it was."

CMP: had to do a plane-change burn just prior to going to bed, resulted in a very long day for the CMP "I knew I was hanging on the ragged edge for being tired." "I was so much over tired that I couldn't go to sleep right away." "always having the muscle twitches in my legs" Dr Berry: "It was close to 24 hours."

<tr>
<td>------------------</td>
<td>--------------------------</td>
</tr>
<tr>
<td>Topic:</td>
<td>Exercise</td>
</tr>
<tr>
<td>Issue:</td>
<td>debrief of individual exercise regimens</td>
</tr>
<tr>
<td>Description:</td>
<td>CDR: his goal was a 10 minute period daily, exclusive of the 2-day lunar surface activity, for both he and the LMP. The CMP was to do that exercise each day. The Exer-gym was to be used, beginning with 1) legs with feet in the two loops and hands controlling the friction device, from a crouch to a full stretch-out. Then 2) hold the fixed loops and use the legs on the movable loops, then 3) hold the fixed loop with the toes and use the biceps and movable loops. These exercises designed to work the &quot;Big 4.&quot; Did not exercise the first day out. While it is in the flight plan, the day is too busy. CDR expressed opinion that the contribution of the 10 minute exercise periods was &quot;down in the noise level&quot; compared to the basic workload of the 30 hours of work on the lunar surface, including the EVAs. When Dr. Berry said &quot;you don't really need it on that first day anyway,&quot; LMP differed, suggesting it &quot;would probably have alleviated some of the sore back muscles that first day if we had gone ahead and done it, in my case, anyhow.&quot; CDR specified exercise prior to lunch every day as the most efficient schedule time.</td>
</tr>
<tr>
<td>General Comments:</td>
<td>LMP limited exercise intensity to just below generating a sweat, felt heart rate increase and increased respiration, but &quot;it's not a vigorous exercise, more of a tension exercise.&quot; Did a hard, slow pull.</td>
</tr>
<tr>

<td>Exercise</td>
</tr>
<tr>
<td>Issue:</td>
<td>exercise routine</td>
</tr>
<tr>
<td>Description:</td>
<td>CDR: goal was about 10 minutes per day exercise for lunar surface activity days for the CDR and LMP. For CMP, ten minutes each day. Planned to use the Exer-genie device. Missed the first day out -not on schedule, LMP thought first day exercise might have helped avoid his sore back muscles the first day. LMP felt he increased his heart rate and breathing rate --tried to avoid &quot;cracking a sweat.&quot; CMP didn't work up a sweat -exercised 5-10 minutes per day, CDR: benefit of exercise &quot;was down in the noise level for the CDR and LMP.&quot;</td>

<table>
<thead>
<tr>
<th>Source:</th>
<th>Medical Mission Debriefs</th>
</tr>
</thead>
<tbody>
<tr>
<td>Topic:</td>
<td>Exercise</td>
</tr>
<tr>
<td>Issue:</td>
<td>how much</td>
</tr>
<tr>
<td>Description:</td>
<td>CMP: first 3 days worked with the Exer-genie, 3 periods every 2 days, maybe. Each period 15 or 20 minutes. In lunar orbit, 2 periods a day, 10-15 min of each spent running in place, using the center couch. And 5-10 min of each period working with the Exer-genie for a total of 20-30 minutes, 2 periods a day. Used 'straight' exercise with the Exer-genie. Not much increase in heart rate with the Exer-genie, but more with the running. CDR and CMP neither could get heart rate over 80 with the Exer-genie. No exercise after the EVAs or on way home. Too busy cleaning up and stowing. CDR: exercised once a day on the way out, using the Exer-genie until it appeared to wear out. Did deep knee bends with feet against the bulkhead, hands against the struts and pushed against his arms. Pull up to about 100 with that. Exercise period about 5 minutes. LMP: Exer-genie once daily for maybe 10 minutes on way out, on the way back strained against the seat restraint until it failed.</td>
</tr>
<tr>
<td>General Comments:</td>
<td>A bungee to the floor for running in place would help, they thought</td>

Additional the Questions:
what exercises did you feel strengthened you the most which ones increased HR most?
### Appendix A
**Apollo Summit Non-Attributable Report**

| Summit Topic: | Yes |
| Source:       | Flight Surgeon logs |
| Topic:        | Food/Nutrition |
| Issue:        | Delete H2O Chlorination |
| Description:  | Chlorine limit is 5ppm but cannot be confirm by taste, as Chlorine does not mix uniformly throughout tank. Will discard the first 5 clicks of H2O before taste |
| General Comments: | Secondary to overwhelming chlorine amount in solution. |

**Resolved:**

If Resolved how, when, where?

**Additional Questions:**

Will Chlorine used in the Apollo era be used for exploration vehicles or newer iodine for potable water sterilization?

| Summit Topic: | Yes |

---

| Source:       | BME logs |
| Topic:        | Food/Nutrition |
| Issue:        | H2O |
| Description:  | H2O smells like a bucket of Clorox |
| General Comments: | Related to inability to adequately stir chlorine in the water tanks after application. |

**Resolved:**

If Resolved how, when, where?

**Additional Questions:**

If we use iodine instead of chlorine will we run into the same problems with a different smell?

| Summit Topic: | No |
Appendix A
Apollo Summit Non-Attributable Report

Source: BME logs
Topic: Food/Nutrition
Issue: Potable H2O tank
Description: Potable H2O tank quantity decrease possible rupture?
General Comments:
Resolved:
If Resolved how, when, where?
Additional Questions: Did the potable water tank rupture? Or has it ever? Do we have a back up if it does? Can we repair it if it does?
Summit Topic: No

Source: Medical Mission Debriefs
Topic: Food/Nutrition
Issue: Crew Preferences & Observations
Description:
- a) Variety is more important than getting what you like. They were on a 4 day rotation
- b) Avoid high calorie foods –unclear why this is the case. Apparently these food types were packed because of the mass-power-volume issues
- c) Food items (beef, chicken sandwich) was “crumbly” -quite a bit of crumbs in the cockpit
- d) Orange juice, clam chowder package broke or split. Crew prefers the soup
- e) Ham & applesauce “grew thick”

General Comments: Specific Food Notations:
1. Pudding, cookies sweet cinnamon toast, chocolate drinks, heavily sweetened fruit drinks
2. Meat dishes were desirable, especially bacon squares
3. CM believe they would have gotten more total calories if lighter foods were available
4. Cut down total calories from 2,500/day to 2000 -2200 day
5. Choose more dehydrated foods and less bite-sized foods. Crew got sick of them towards the end of the mission
6. The H2O gun was very hard to operate -got stuck often. Also heavy Chlorine taste secondary to inadequate stirring after ever 12 hours of application.

Resolved:
If Resolved how, when, where?
Additional Questions:
Summit Topic: Yes

<th>Medical Mission Debriefs</th>
</tr>
</thead>
<tbody>
<tr>
<td>Topic:</td>
<td>Food/Nutrition</td>
</tr>
<tr>
<td>Issue:</td>
<td>Food Preferences and Observations</td>
</tr>
<tr>
<td>Description:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>a) The crew mixed H2O with grape juice to kill the awful chlorine taste in the water</td>
</tr>
<tr>
<td></td>
<td>b) Stomach fullness from the gas in the water and busy mission schedule precluded 3 meals per day. Crew averaged an a.m. and p.m. meal, however, rarely felt hungry. Exception was rendezvous day where they had gone approximately ?? hours between meals</td>
</tr>
<tr>
<td></td>
<td>c) “Meat Stick” – Turkey and gravy, dried fruits were well-liked by the Crew</td>
</tr>
<tr>
<td></td>
<td>d) Plain bread was preferred over rye without condiments. Rye seeds took on peculiar odor</td>
</tr>
<tr>
<td></td>
<td>e) Fruit preparation was also well-liked</td>
</tr>
<tr>
<td></td>
<td>f) Food preparations was cumbersome. Crew preferred the food packs with great-beef stew, chicken &amp; rice. Also, food delivery was an issue. Eating spaghetti and meatballs out of a tube was not desirable</td>
</tr>
<tr>
<td></td>
<td>g) Once food was prepared, the lack of availability of useful areas to store water, food packs, etc., made eating difficult, i.e., each packet had to be finished otherwise, it would float away...one crewmember stated &quot;you have no place to put it&quot;</td>
</tr>
<tr>
<td></td>
<td>h) Boiling point of water at 5.0 psi is 154 degrees Fahrenheit plus or minus 4 degrees- Steam in water contributed to gas problem</td>
</tr>
<tr>
<td></td>
<td>i) Crew recommended for Apollo to have many wet pack meal readily available and vacuum seal items like bread, snack, etc. Benefit = ready made, no prep time and easily available.</td>
</tr>
<tr>
<td>General Comments:</td>
<td>Crew was unsure secondary to lack of sensation of hunger secondary to gas in stomach from the water. Also they felt that physically they weren't working that hard.</td>
</tr>
<tr>

Questions:
Summit Topic: No

Source: Flight Surgeon logs
Topic: Food/Nutrition
Issue: water bags
Description: Too much restriction to flow on water bags

General
Comments:
Resolved:
If Resolved how, when, where?

Additional
Questions: So we have fixed the gas in the water but created a new problem? Is this an improvement or just a change of big problems?
Summit Topic: Yes

Source: Medical Mission Debriefs
Topic: Food/Nutrition
Issue: Crew Observations
Description: Food was outstanding

General
Comments:
Resolved:
If Resolved how, when, where?

Additional
Questions:
Summit Topic: No
### Source: BME logs  
**Topic:** Food/Nutrition  
**Issue:** scale  
**Description:** scale nut came off but got it back on  
**General Comments:**  
**Resolved:**  
**If Resolved how, when, where?**  
**Additional Questions:** What if the nut was lost could we replace it? How would this effect the mission?  
**Summit Topic:** Yes

### Source: Flight Surgeon logs  
**Topic:** Food/Nutrition  
**Issue:** can they keep food  
**Description:** Concern of a crewmember having FD1 nights tuna fish and may be sick  
**General Comments:** turned out he didn't eat the tuna  
**Resolved:**  
**If Resolved how, when, where?**  
**Additional Questions:**  
**Summit Topic:** No

### Source: Flight Surgeon logs  
**Topic:** Food/Nutrition  
**Issue:** scale broke  
**Description:** Scale used to weigh the feed water quantities broke “the nut on the top came off”  
**General Comments:**  
**Resolved:**  
**If Resolved how, when, where?**  
**Additional Questions:**  
**Summit Topic:** No
Appendix A
Apollo Summit Non-Attributable Report

Source: Flight Surgeon logs
Topic: Food/Nutrition
Issue: water
Description: water is the same with and without filter

General Comments:
Resolved:
If Resolved how, when, where?
Additional Questions: Explain same? Did it taste the same or same temp? Did it taste the same or same temp?
Summit Topic: Yes

Source: Flight Surgeon logs
Topic: Food/Nutrition
Issue: water filter
Description: Concern of water gun filter by crew-filter taken off

General Comments: Fear of filter be contaminated? It was alluded to but not directly said?
Resolved:
If Resolved how, when, where?
Additional Questions: What caused you to question the filter on the flight and not before?
Summit Topic: Yes

<td>Food/Nutrition</td>
</tr>
<tr>
<td>Issue</td>
<td>Food packaging</td>
</tr>
<tr>
<td>Description</td>
<td>CMP: Available time was more a determinant of eating than was the societal factor of other crew eating at the same time. During the transit to the moon, there is more time for eating than in lunar orbit, when there is very little time, particularly when one needs to troubleshoot equipment, etc. One can get to canned packs quickly and so that's what you eat when you are in a hurry, rather than re-hydrated packs. CMP lost ten pounds while remainder of crew lost about 1 pound each. CMP attributed his weight loss during mission to a poor diet the last few weeks prior to launch, when he drank 2-3 beers in the evenings. CDR: compared the food intake with the activity level -- when activity level is high, &quot;wet packs and cans&quot; is all you have time for. Food preparation could be time consuming, limiting consumption during high activity times. CMP: all bite-sized packages were consumed -&quot;that was the best thing we had.&quot; Tasty and quick. &quot;You just flip that off and a can of juice, and you could go at it.&quot;</td>

<tr>
<td>Issue:</td>
<td>food packaging</td>
</tr>
</tbody>
</table>
| Description:     | "Those cans are a hazard. You tear the lids off those things and that's like a knife just floating around the spacecraft."
|                  | Speaker observed opening cans which are sitting on a tray. A tray was not part of Apollo. |
|                  | After use, a germicide pill was placed in the can. CMP discarded the whole thing in a fecal bag. Once a can or package was opened, the entire contents had to be eaten because there was no way to dispose of partial contents, which could float throughout the cabin if not properly stowed. Liquids which were conductive posed electrical threats for shorting out circuits. Can tops posed a laceration threat, Crumbs posed an ocular foreign body threat. Multiple items could not be manually controlled in zero-g during the eating process. After eating, the small, compressed volume of packaging is now a much larger volume, no longer compressed and fitted into a container. A trash compactor is needed. Used food packaging was wrapped and taped into a ball which was stored in a jettison bag. The planned trash stowage volume was rapidly exceeded. |

### Source: Medical Mission Debriefs

### Topic: Food/Nutrition

**Issue:** food quantity consumption

**Description:** "I'm convinced when you get in flight and your heart powers down and you do less work, you just eat less. And you go in a power-down state; three meals a day in a 16 hour day approaches absurdity,"

Consumed wet packs like gangbusters. Some wet packs need to be hot, they would have been much more palatable.

**General Comments:**

**Resolved:**

If Resolved how, when, where?

**Additional Questions:**

**Summit Topic:** No

---

### Source: Medical Mission Debriefs

### Topic: Food/Nutrition

**Issue:** corn chowder

**Description:** "It triggered a Captain's Mast and restricted crewmember to quarters for the rest of the mission, except the lunar surface, and eliminated corn chowder from everybody's diet right there."

"everything triggered"

**General Comments:**

**Resolved:**

If Resolved how, when, where?

**Additional Questions:**

**Summit Topic:** No

### Source:
Medical Mission Debriefs

### Topic:
Launch/Landing Suit

### Issue:
Suit Observations

### Description:
- a) Crew did not experience tumbling sensation getting into or out of the suit as other crews had
- b) Commander reported his hands "got wet and red as blood" during lunar EVA
- c) Crew was able to bend down to knees and get up without problem

### General Comments:

### Resolved:

### Additional Questions:
- Were the Commander's hands getting wet and red as blood a suit fit issue? Did this cause a problem? Or LMP?

### Summit Topic:
Yes

---

### Source:
Medical Mission Debriefs

### Topic:
Lunar Dust

### Issue:
Lunar Dust Observations

### Description:
Crew reports that they were quite dirty with dust upon return to LM
- 1. Suits were covered with dust to the knees and gloves
- 2. Dust seemed to settle on floor in LM even upon return to microgravity
- 3. Crew did not need to don their helmets in microgravity
- 4. Very fine grained material
- 5. Dust covered the gloves and was rubbed off onto their hands. They were not wearing glove liners
- 6. Crew would wipe off with tissue, then wet a towel and wipe off following removing the LPG
- 7. Dust was not noticeable in CM following the LM docked

### General Comments:

### Resolved:

### Additional Questions:
- Should crews wear glove liners to prevent getting dust on their hands? Is there containing dust? i.e., carpeting?
- Should crew some how wash off before returning in LM?

### Summit Topic:
Yes

---

### Source:  Flight Surgeon logs  
### Topic:  Flight Surgeon/Crew Interaction  
### Issue:  Sleeping bags no good  
### Description:  Sleeping bags no good prefer couch, secondary to inability to bring both knees to chest to relieve back pain.

### General Comments:  
### Resolved:  No  
### If Resolved how, when, where?  
### Additional Questions:  What was wrong with the sleeping bags and how was the couch better?  
### Summit Topic:  Yes
## Appendix A
### Apollo Summit Non-Attributable Report

**Source:** Flight Surgeon logs  
**Topic:** Flight Surgeon/Crew Interaction  
**Issue:** Cold symptoms treatment  
**Description:** Crew asked about using Rx if symptoms of sinus drainage and ear pain. FS concerned about lack of fever to diagnose a sinus infection  

**General Comments:**  

**Resolved:** Advised crew to continue nasal decongestants. No antibiotics without fever  

**Additional Questions:** Will our medical approach differ for exploration missions from what we see now?

---

**Source:** Medical Mission Debriefs  
**Topic:** Flight Surgeon/Crew Interaction  
**Issue:** Crew Observations  
**Description:** a) Crewmember felt surgeon was not concerned about in-flight Illness (cold)  
    b) Limit discussion of problems to individuals who are intimately familiar with the problem and the solution (problem with lack of PMC)  
    c) "Communications were bad because too many people got into the act (Hot Biomed harness)  
    d) Crewmember encouraged FS to act as more of an advocate of the crew than "as an experiment"-with regards to the flight plan demands on the crew. (see General comments)  
    e) Crew concerned FS was withholding antibiotics for sinus infection.  

**General Comments:** Apparently, the crew was asked to do an unscheduled TV show-Crewmember saw that two other crewmembers refused to do it. Surgeon needs to be sensitive to that.  

**Resolved:**  

**Additional Questions:** What was the PMC schedule for this mission? *Notes scribbled on the side of FS Log possibly at 97:23 as PMC with crew health status reported.

**Summit Topic:** Yes

Appendix A
Apollo Summit Non-Attributable Report

Source: Medical Mission Debriefs
Topic: Training
Issue: Simulation
Description: a) The pogo and centrifuge were good training activities to simulate LEVA. as far as ambulation goes 
b) Training simulated the LEVA activities pretty closely.

General Comments:
Resolved:
If Resolved how, when, where?
Additional Questions: Will pogo simulators be used to train for mission?
Summit Topic: Yes

Source: Flight Surgeon logs
Topic: Training
Issue: docking problems
Description: 4th attempt to capture with probe unsuccessful

General Comments:
Resolved:
If Resolved how, when, where?
Additional Questions: Was the probe a hindrance in all Apollo missions during docking?
Summit Topic: Yes

Source: Flight Surgeon logs
Topic: Training
Issue: Docking
Description: 4 unsuccessful docking try with probe try to dock with probe retracted "hard dock finally accomplished"

General Comments:
Resolved:
If Resolved how, when, where?
Additional Questions: Was docking with probe better than without?
Summit Topic: Yes
Source: Medical Mission Debriefs
Appendix A
Apollo Summit Non-Attributable Report

Topic: Training
issue: EVA work vs sim training for EVA
Description: p. 25: LMP: An order of magnitude easier than our 1G training. Never really felt tired. Stayed well-hydrated. Managed the plan!
CDR: easier to get around on the lunar surface, travel faster and easier. Did not feel uncomfortable at all during EVA-1. During EVA-2 was aware of workload effect on respiration rate. Did not feel 'overheated.' Noted a little sweating, probably limited by the Liquid Cooling Garment (LCG)--used medium flow in LCG when he felt sweaty or flush. Took short rests only on the steepest slopes of the crater, then proceeded "Never really felt like I was behind the power curve as far as the total workload was concerned."
CDR noted their 2-day workload was, in his opinion, "about as heavy a workload as anybody ought to do.

General
Heart Comments: Dr. Berry noted heart rates over 150 at times for the CDR and LMP during EVAs. Rates slowed with rest during the EVA.
LMP affirmed that if consumables were increased they could increase and extend their EVAs.

Resolved:
If Resolved how, when, where?
Additional Questions:
Summit Topic: Yes

Source: Medical Mission Debriefs
Topic: Education of crew on Med requirements and rationale
Issue: CDR: Medical training has been left to the last seven weeks prior to launch. Crew has not understood the rationale or specifics of requirements such as why the need for repeated 24-hour urine collection and multiple blood draws. Suggested early in the training syllabus medical time should be allotted to define the medical requirements, their rationale and their goal, including the theoretical underpinning, the mechanics and the protocol. At this time in the program, “medical requirement” still have not been formalized in any document.

General Comments:
Resolved:
If Resolved how, when, where?
Additional Questions:
Summit Topic: Yes

Topic: Training
Issue: Fatigue
Description: a) The crew was very fatigued (mentally) prior to launch secondary to very busy training schedule. Work day days typically began at 07600 and would end with debrief at 2200-0000 each night. Approximately three weeks before launch.

General comments:

a) Solution: Train/work late for a fixed launch date or flexible launch date once the work is done. Other options is to skip non-essential meetings

Crew Recommendation: Crew recommended that the crew should use the 1st couple of months before launch for simulation training only; including sleep/rest, exercise and eating. That's it. Get all the technical briefings, systems briefings, and physicals done at L-60 or L-90. Also having simulations as your only planned event 60 day's before a mission would leave room for unplanned events i.e., some days will require 10-12 hours for sims, other days only 3-4 hours

EVA Suit

Crew Medical and Safety Issues
EVA Suit Crew Medical & Safety Issues

Ambulation and Center of Gravity (CG)

1. What do you recall about the CG of suit during walking vs. during stationary working? Would it have been better if the CG was low and forward vs. high and aft?

   It probably would be better if CG was a little lower, but the human body will adapt regardless. Reducing the size and weight of the backpack would help solve the problem. Backpack and suit on Apollo weighed 194 pounds.

   Reduce the mass of the suit by a factor of two, general mobility by a factor of four.

   Glove needs to be like a human hand.

   Don't make moving the CG your primary priority. Move the CG only if it becomes convenient to do so while taking care of other issues like reducing the mass of the suit, etc. Human beings are very adaptable and we were certainly comfortable by the third excursion.

   You automatically leaned forward when you were standing and you learned how to run at a fairly significant velocity with dynamic stability.

Post-Summit Questionnaire Responses

Soldiers for thousands of years put the weight on their backs.

2. Debriefs imply loping was the most biomechanically efficient form of movement. Was this in part from suit restrictions, or was it the most natural movement in 1/6 g? Was the workload perceived as higher with walking slowly vs. quicker loping or hopping?

   It was a natural response to take the easier way to move which was by loping or skipping. Always try to set up a dynamic motion.

   The metabolic cost was less with skipping than with walking. It took more time and was more difficult to walk. It was very comfortable in the 1/6 g environment. Crewmembers adapted quickly and were comfortable within 5-10 minutes and got better with each excursion. It didn't interfere with the efficiency of operations, even in the early part of an excursion. There were many factors that cut efficiency, but that was not a major one.

   Ambulation tended to be somewhat variable with each individual and whether they ultimately selected the most efficient way to do it will be determined in the tests that are being conducted.
A cross-country ski technique was used by one crewmember that had quite a bit of cross-country skiing experience, but the films showed that others tended to develop the same method.

Some liked hopping or skipping instead.

There is an ongoing quantitative analysis looking at speed and efficiency using biomedical and photographic data from Apollo and this is a good effort. There are a number of sequences that can be used from the television data so crews can be advised on what might be the most energy-efficient way to move. With the equipment available now one can decide what will work best. You can give them good advice on that.

Post-Summit Questionnaire Responses

No responses

a. Obviously you preferred to hop and we’re seeing in the testing that you’re metabolically more efficient going at faster speeds. If you’re trying to do detailed observations and so forth where you don’t want to go fast, did you feel compromised in the suit? In other words, the suit is set up to go fast and it’s optimized metabolically for that. Did you feel compromised when you were trying to work at a station or area to bend over and pick things up, etc?

Due to the design of the suit, you didn’t normally bend over. That’s why there was a need for tools with long handles. If you really wanted to get down close to something, you’d just go down as a push-up or lean against a rock.

Bending the knee was in the suit.

Some crewmembers mentioned that it was fatiguing to go uphill, which is probably because they were trying to bend their knees. We need a better knee joint.

Post-Summit Questionnaire Responses

CMP: his EVA was from the orbiting CSM. Neither weight nor mobility was a problem.

b. Did you feel that the hip mobility was adequate?

As you can see from the video footage, we were running, and the motion was primarily at the hip. It was easy and ankle mobility was good as well. The problem was primarily with the knee.
3. Did any muscles feel more fatigued than you would have expected, during ambulation, for the degree of exertion? If so, which muscle groups?

Hills seemed steeper and tougher to climb on the lunar surface and loping couldn't be used. It was fatiguing to walk uphill.

General fatigue was experienced, with thigh muscles specifically affected.

4. Was there any particular muscular strain noted when trying to slow down, or stop, from a quick lope?

No, however the stop needed to be anticipated.

5. Did you feel the suit was too heavy, too light, or about right?

It was substantially too heavy.

A lightweight suit would be easier to operate and much more comfortable.

Assembling the suit was a complicated process, partly due to the small area allocated in the module. If a larger area was available, it may have been easier.

a. What about the mass issue when it comes to your movement and your ability to negotiate turns and things of that nature?
You adapt to the fact that you have a lot of inertia relative to normal walking or hiking on Earth, because the mass certainly hasn't changed and you have to be conscious of that.

Your total weight is only about sixty pounds, even though you're carrying around 370 pounds of mass. You adapt to that, but on the other hand it is one of the reasons why you work harder than you would like to on the moon. It takes energy to climb a slope or something like that. You'd like to use that energy for more productive tasks.

Post-Summit Questionnaire Responses

No responses

b. What would you recommend as a target mass reduction?

My target for mass reduction has always been a factor of 1/2, but anybody can come up with a number.

There are some advantages to having some mass, particularly if you don't fix the flexibility of the knees. You can use that mass to help you bend the knees, but I assume that there will be a much more mobile leg than we had during Apollo.

Thinking in terms of Mars, I hope we will build a new heritage for suits. There are other suit issues, since the 3/8 gravity is a significant increase over 1/6.

Post-Summit Questionnaire Responses

No responses

c. Do you think you could have a suit that was too light? Picture yourself working on the moon with an ultra light suit. It strikes me that somewhere between microgravity and 1/6 g you're going to want some restraint to do work.

Hypothetically you could have too little mass, but again you would adapt to that. If you need to push against something, you just lean more. You depend on the adaptability of the human beings to take advantage of whatever situation they are in and 1/6 g is an environment you can take advantage of.

It's something you can test, if it doesn't cost too much. Assume there would be an energy savings by reducing the mass. This would be a distinct advantage over anything else that might be a problem.

Reducing the mass of the suit is probably not an important goal, as much as improving the glove.

Post-Summit Questionnaire Responses
No responses

6. **What were the characteristics of the suit walking up or down slopes? Any muscular strain noted?**

Ambulating down slopes was difficult because it was hard to arch the back in the 4.26 psi pressure suit.

Hopping or parallel skiing was actually used to ambulate down slopes. It was necessary to be more cautious going downhill. If you lost control, you could possibly roll down the hill.

No muscle strain occurred while hopping or parallel skiing.

*Post-Summit Questionnaire Responses*

3.75 psi pressure suit (not 4.26)

7. **What were the characteristics of the suit climbing up and down the ladder? Any muscular strain noted?**

The ladder did not cause a problem, although glove improvements would have decreaded the concern of falling. It might be helpful to have a line attached to you so you wouldn’t fall off. On the ladder, the suit issue was getting through the hatch.

*Post Summit Questionnaire Responses*

No responses

8. **Based on experience with the LM ladder, would a taller ladder be a significant concern for falls and loss of balance? If so, how to mitigate.**

Better glove performance is probably the most important, although we really didn't have any problems going up and down the ladder. We actually didn't use the steps, but would just grab the rails and slide down and you tend to pull yourself up with your hands more than with your feet. That was partly because of the low mobility in the knee.

If it is a weight trade-off of any significance, don't worry about the rails. The sides of the ladder provide all the gripping surface that you need.

We learned a lot about how to get equipment and ourselves in and out of the lunar module. At first, we used a clothesline or pulley system to get equipment out. We quickly abandoned that and just started dropping it to the person that was already on the ground.
You start doing things in a much more efficient manner once you learn that height is not an issue in 1/6 g. You just shove the equipment out the hatch and the other crewmember takes care of it.

Some equipment was hung with a strap on the side of the module.

The rung width and height on LEM were good.

*Post-Summit Questionnaire Responses*

No responses

**9. Did the body postures required to navigate the LM hatch for ingress/egress cause undue muscular strain?**

There was no strain on the back or other muscles and no residual soreness in any muscles. The back had to be arched and the heart rate went up.

The design of the hatch was the problem. Crewmembers had difficulty maneuvering through and one of the primary reasons was that the DSKY of the primary navigation and guidance was directly above the hatch. That is one thing you would hit and you didn't want to hit it very hard.

The suit was the max limit with the backpack. You had to arch your back to fit in and crewmembers had to help each other get through. The highest heart rate occurred while getting in and out of the hatch.

You need a hatch that is sized appropriately for an inflated 1/6 g pressure suit. If changes are made in terms of mass mobility, it will be a non-issue in the future.

If an airlock is used in the next lunar lander design, it may make ingress and egress easier and will also be a good idea from a dust control standpoint.

*Post-Summit Questionnaire Responses*

This hatch thing was obviously easier in 0g.

**10. Debriefs implied resting in the suit while standing was comfortable. For future EVA ops, would some form of resting seated bench, or tripod support offer any advantage during rest periods (aside from sitting in a rover seat)?**

The suit was self-supporting. You can rest your arms on the suit.
There was no feeling of the need or opportunity to rest. Psychologically we didn't want to use the time because we were already behind.

A suggestion was made for suits to be custom-made for each individual crewmember. Need to have custom sized utility suits available as well.

*Post-Summit Questionnaire Responses*

No responses

11. Did you experience any 'vertigo' during entry into a 1/6 g field, and with activities on the lunar surface?

Minimal or no symptoms occurred.

However, the crews' remarked in the debriefs that they were "wobbly" upon initial contact with the lunar surface. This was short-lived and did not result in any compromise in their gait or ability to perform activities.

*Post-Summit Questionnaire Responses*

No responses

12. What aspects of the suit were specifically troubling in performing routine tasks with regard to workload and injury?

See information above regarding glove issues, suit mass, lack of flexibility in the knee joints.

*Post-Summit Questionnaire Responses*

The primary issues were glove tactility, suit mobility, contingency capabilities and crew controls.
- The great amount of energy needed to move around
- First attributed to the fact that mis-fitting suit joints were not co-located with the subject’s joints
- Every motion required compressing the suit volume, a potentially fatiguing activity, this didn't turn out to be as bad as we'd thought but it took a long time to figure out what were our real issues.
- Our test program did not identify any knee joint problems -two reasons. 1) testing was done standing up, climbing stairs and walking. 2) given the weight of the EMU, having a semi-rigid knee joint actually made life easier for us.

*Vision*

1. Was the field of view out of the helmet adequate to see displays (in terms of near/far vision factors)? Was the view adequate to avoid trip hazards and maintain footing?
Was the horizon reference in your peripheral vision adequate, with the side shades down, to ensure good vision and balance?

Everything was visible, however would have liked more peripheral vision. It was less efficient to have to turn your body rather than just turn your head. Peripheral vision should be improved. It did not interfere with functionality, just needed to turn your body.

It was difficult to know what the other crewmember was doing and you would have to turn from your task to view crewmember.

Visibility was also limited because you couldn't bend over easily and you had the camera in front of you. Hopefully we will have a far less bulky camera system that you can point and shoot. There was a tendency to work around those kinds of difficulties and we were able to do that, but they were still there.

*Post-Summit Questionnaire Responses*

More head movement would have been good

You don't have to be in lunar environment to know this

a. You had mentioned that you couldn't see your feet and you adapted to that, but all things being equal would it be better if you could see your feet?

It is always better to be able to see your feet, but when you're walking normally you usually are anticipating several steps ahead and you can do that on the moon, too.

*Post-Summit Questionnaire Responses*

Do you do this on Earth?

b. In deep sea diving, there are helmets that have a neck ring and it has a liner that fits to your head so you can turn you head, rather than your whole body. Do you think that feature would be worth looking into on a lunar suit?

Yes, look into that. It's always going to be more efficient to be able to turn your head.

*Post-Summit Questionnaire Responses*

Obvious
2. Given possible new in-helmet Heads Up Display (HUD) technology, would such displays be valuable, or potentially distracting and contribute to slips/falls?

The complexities and desired information of the HUD should be considered and should not be a distraction. The checklist would be a nice feature to have.

The HUD and other fancy things are nice, but I question whether the complexity and reliability over long-term flight is really going to help or hinder. You have to have back-up systems that are somewhat manual. We had back-up systems right down the line. The more complicated you get with how you get information to the suited crewmember, the more risk you run of losing that system, so be careful.

Dr. Jones responded: We talked about simplicity and that's a really good point, but at the same time we're trying to diminish the overhead that the crew had and if you have to strain to look down at a cuff checklist, it's taking your time. If we could do it in a way that's pretty easy for you, we'd like to do that as long as it's reliable and tested.

Determine the benefit, cost, and reliability of the system. If it turns out that it's not reliable or when you start to work with it you find it can be done just as well with a cuff checklist as with a HUD, then change your approach.

A reliable HUD displaying consumable information or feedback when depleting key resources or medical information could be useful.

*Post-Summit Questionnaire Responses*

Reliability is a big factor.
As the fighter pilot

a. You mentioned that it would be nice to have the ability to call up displays, not that you wanted them constantly running with a lot of confusing information, but using an auditory cue call up information you wanted to see. Would this be helpful?

Yes, the HUD primarily should be presenting the operational information that you need at the instant. If you want to see oxygen, you say "oxygen" and it appears.

*Post-Summit Questionnaire Responses*

Cost
**Suit/Boots**

1. **What tasks were the most fatiguing to perform in the suit? What tasks required the most dexterity?**

   Tasks related to the hands were the most fatiguing.
   
   Tasks requiring finger dexterity, such as holding anything tight (i.e., hammers, drills, changing camera settings), were especially difficult and fatiguing.
   
   More flexibility in the glove is necessary.

   *Post-Summit Questionnaire Responses*

   Better gloves needed. Head mobility would reduce body motion.

2. **Within the limits of the suit, did the posture used for kneeling activities cause back/leg strain? What level of knee padding would be advised for protection?**

   Kneeling used extra energy. If the suit was more flexible, kneeling would be used more often.
   
   Kneeling allows you to be closer to whatever is being worked on; however, it could exacerbate the dust problem.

   *Post-Summit Questionnaire Responses*

   No responses

3. **Were there any pinch points, pressure points, or areas of abrasion in the suit?**

   A lot of abrasion and scraping occurred in the hands and gloves and at times caused blood under the nails and pulled them off at the quick.
   
   This occurred only on the lunar surface, not training.
   
   The skin on the back of the knuckles was abraded in some crewmembers, never in training, only on the moon.
   
   This could have been incapacitating for future EVAs if had been doing repeated ones.
   
   Fix the Gloves! -possibly due to lack of use of comfort glove and hands being soaked with sweat in the glove.
Post-Summit Questionnaire Responses

No. On a 40 minute EVA from the CSM

4. Did the boots provide adequate traction and tactile feedback to your feet for maintaining good ambulation control?

There were no problems with the boots. There was no concern about ankle sprains or injuries with falls. You may find places on the moon where you're going to be walking over bare rock, although that isn't very likely. In that case, you'll find the little spheres of glass in the regolith will cause it to be slippery and the boots don't deal with that very well. If you get off the ladder and put your foot directly on the side of a boulder, it was slick, but this will very rarely be a problem.

Post-Summit Questionnaire Responses

No responses

a. With respect to the boot, did you feel like you were getting enough information to have a stable gait? The boots were hard on the bottom, with galoshes over them.

They were very comfortable. It never seemed that the boot was causing any difficulty.

The lunar regolith is a very efficient transmitter of acoustical energy and you can actually feel somebody hammering on a core probe through your boots, if you are close enough. The energy is focused and it goes through the soil very efficiently.

Post-Summit Questionnaire Responses

No responses

b. In regards to the coefficient of friction on the surface, did you feel slippery on the regolith?

It was never slippery on the regolith. It has a very high bearing strength. It has been tamped by micrometeorites over a very long period of time.

The upper layer is a little looser with less bearing strength, so that gives you a grip.

Also, every particle is like a tiny piece of Velcro. It hooks with every other particle, so the coefficient of friction is pretty high within the regolith material itself.
5. Was ankle support adequate to avoid ankle injuries with unequal footing?

There were no issues. Always observant as to where you were placing your foot so as not to have any injuries.

Lighter weight suit may have more vulnerability. The suit gave a sense of support and protection.

6. Were there any pressure points with boot inserts or with the lunar boot instep strap? Was arch support adequate? Would proper arch support designs be advised for frequent EVA activities?

No discomfort with the boot.

7. Did the lunar boots provide adequate thermal comfort?

Yes.

8. What lunar surface EVA activities (e.g., egress down the ladder, ingress, use of tools, rover ops, etc) do you feel pose the greatest risk for injury?

The Lunar Rover pilot was at greatest risk. He would be the first one to get hit when driving on the side of a hill.
The commander on the high end was concerned about falling over.

Post-Summit Questionnaire Responses

No responses

9. **What features in future suits would be most beneficial to reduce workload, and reduce the potential for injury and falls?**

As discussed above,

- Gloves
- Knee flexibility
- Mass.

Put pads in the knees for kneeling on the regolith.
Also use a self-sealing pressure garment, to take care of a small puncture.

Post-Summit Questionnaire Responses

Test Operations

- During testing - subjects were never matched to the suits – difficult to sort out if problems were due to design or mis-fitting suits
- Before unloading the suit with artificial load relief, take a look at the impact they have on test operations. The use of load relief was so obnoxious that when it came time to do our final thermal-vacuum tests, I elected to work unencumbered by load relief. I thought the potential for getting tangled up in pulleys, cables, etc. that I could not see or reach, was a greater hazard than the risk of losing suit pressure and having the whole thing fall on me.

a. **Discuss soft suits versus hard suits and the trade off.**

From the Apollo crew point-of-view, there is a tendency to favor the soft suits, but we didn’t have much experience with the hard suits.

Everybody should be objective enough to look at it. The next set of explorers will need to determine what they like best and weigh the advantages against the disadvantages.

Post-Summit Questionnaire Responses

No responses

Hands/Gloves

1. **Did certain activities on the moon cause finger/hand pain vs. fatigue?**
The most fatiguing part of the tasks was repetitive gripping which caused fatigue in the musculature of the forearm.

The crewmembers were unable to specify cause of problem.

There were issues with not only fingernails being pulled back (onycholysis), but also a situation of skin being abraded from the top of the knuckles.

*Post-Summit Questionnaire Responses*

No responses

**2. Were hand/finger issues on the moon different than any issues encountered during ground training runs?**

We saw no trauma in training, though muscle fatigue occurred. Training sessions weren't as long as the lunar sessions, though.

The very long terrestrial sessions developed the same kind of problem, so it's either a duration problem or in some cases it may be related to the dimensions of your hand, which needs to be looked at.

Energy, time, and money should be spent to take a serious look at how to improve the glove. Although there have been improvements for Shuttle and Station, the gloves probably aren't as far along as they need to be for exploration activities on the moon or Mars.

Another part of the problem is pressure of the glove. The lower the pressure, the less strength it takes to manipulate.

If you decide to move back towards a single gas low pressure oxygen system, you need to realize there are complications in doing that system because of things that have happened since Apollo.

We tried to list all the operational advantages to having a low pressure single gas system and that is well worth a very hard second look.

*Post-Summit Questionnaire Responses*

No responses
3. Any specific glove touch-temperature issues when handling materials? (ladders, tools, rock specimens, controls)?

No, although thermal input from the sun was felt at one point.

*Post-Summit Questionnaire Responses*

With improved insulation, don't forget that once the insulation heats up, it's really hard to remove the thermal content. One of our final tests was to demonstrate I could pick up a two hundred something degree rock and hold it for 15 seconds or so. Using a metal bar heated to the desired temp, I was able to grasp and hold for 10 seconds or so until the inside of the glove became very hot. Fortunately, since the suit didn't fit, I was able to pull my hand entirely out of the glove.

4. Did any dust get into the inside of the suit between EVAs in the LM? Was there any cumulative skin irritation on the hands or elsewhere from dust exposure between EVAs? Did this affect a subsequent EVA? Did the EVA aggravate any irritation?

No problems, except dust accumulated in the neck rings.

*Post-Summit Questionnaire Responses*

and wrist rings on A-16.

5. What, if any, feature of the space suit gloves would be most beneficial to improve with regard to hand injuries?

The hands were not used in any significant way. Efficiency was probably no more than about ten percent of the use of the hand.

Step back with a clean sheet design of the glove with the goal of getting as close to normal dexterity and use of the hands as possible.

Crewmembers had difficulty with repetitive grasping because it caused fatigue in the forearm muscles. The longer you're out there, the more problems you have.

And, almost everybody on the moon had problems with fingernails.

Spend some money and time working the glove issues, adding dexterity, lowering the pressure in the suit, if possible, as well as trying to diminish fatigue from gripping tasks and to diminish trauma to the hands.

Make easy to don and doff; give room in the airlock if you have room to get the suit on easily, if you are going to do frequent EVAs.

*Recommendations for the glove:*

338
• Consider the inherent design of the gloves.
• Possibly a robotic hand could be used or a mechanically-augmented, power-assist glove for repetitive tasks.
• Modify fit and size. Properly fit the gloves to the crewmembers after they are designed and assigned to them. One crewmember had his gloves cinched up so tight that he lost all of his fingernails when he got back. It wasn't due to the glove, but because he had them fitted so tight.

Post-Summit Questionnaire Responses

Look at a wrist seal and depressurized glove. Perhaps even for temporary use on challenging tasks.

• Gloves were the most obvious challenge - required a significant level of thermal protection.
• Multilayer insulation worked on the back, but the palm and interior required a thermal barrier that could withstand abrasion and compression.
• The real issue was simply the need to compress the palm side insulation.
• Perhaps contemporary materials will allow developing a thin, flexible mesh with high conductivity that could be used to interface with an active heat rejection system for future explorers.

a. Unanticipated changes occurred in 1/6 g environment that contributed to the problems with the gloves on the moon’s surface. Could you elaborate on that?

It may be related to the length of time in the glove, since the fingernail problems did not occur during training.

Once fitted for the gloves, the crewmembers were left on their own to figure out how best to use them and that was appropriate, but with experience the crews could be advised of what may work and may not and test various things.

Even wearing silk liners and cutting nails as short as possible, the fingernail problems were not prevented.

The fingernails still scraped against the bladder. With a bare hand in the glove (without silk liners), severe chafing was experienced by at least one crewmember.

There are many nuances that are probably worth exploring, even with a new designed glove.

Post-Summit Questionnaire Responses

No responses

Physiology/Performance/Hydration/UCD/DCS/Thermal

1. Would you like to know your own heart rate, metabolic rate, or other physiological information during an EVA?

We could feel what was happening with our bodies and responded accordingly.
Intermittent feedback was received from CAPCOM regarding suit information/consumables and it was acceptable.

A heads-up display would be acceptable, esp. with verbal request for heart rate, esp. on Mars when don't have mission control watching over you.

It may have helped one of the lunar EVA crewmembers to have heart-rate information as he was going too fast and injured himself during a coring activity.

**Post-Summit Questionnaire Responses**

Would have helped on Gemini IX and XI.
Potassium depletion was a problem. Some way of monitoring condition would be good.
GT-XI - Heart rate is not a reliable indication of work load. Perhaps the most important physiological parameter is hydration.

2. Describe your food and water intake prior to the EVA terms of amount and timing?

We always had breakfast before going out.

We ate fairly well on the moon, but it would have been nice to have more water available, if only in the event of a contingency. Some crewmembers may have been conservative with the available water, but that was wrong. In desert survival, you learn that you should drink the water you need when you have it, rather than partialing it out.

There was a consensus among the crewmembers that having a larger water supply would have been helpful and useful.

You lose a lot of moisture, even with the LCG.

It would be important to have some food available, something that could provide a good lunch.

The fruit bar mounted inside the suit was sometimes problematic because you couldn't always get to it.

A liquid drink with energy nutrients might be an option, as long as it doesn't contain caffeine.

Once suited up, we sometimes went 10 hours without a break. Adrenalin was a factor and we had a lot to do. If it is convenient to get to, having a solid or liquid carbohydrate would be helpful.

Don't overcomplicate things. Keep it as simple as you possibly can because human beings can adapt to these kinds of situations very easily.
Post-Summit Questionnaire Responses

It would be a good thing if there were a simple, non-invasive, way to evaluate hydration in real time. It’s been my experience that you have to force yourself to drink often, especially in the suit, because it’s generally a nuisance task.

3. How thirsty did you become during an EVA? By the end of an EVA?

See #2 above.

Post-Summit Questionnaire Responses

No responses

4. Did you feel the amount of water in the bag was sufficient

It would have been nice to have more

Post-Summit Questionnaire Responses

No responses

5. Given adequate compatibility with the suit, do you feel other liquids such as Gatorade or juices should be a crew option for the drink bag? (In light of the Apollo 16 orange juice leak in preparing for EVA #2)

High energy drink with nutrition would be good, but it’s nice also to have some plain water.

Post-Summit Questionnaire Responses

AW: Need to keep chemical balance in body.

6. Debriefs show a number of crewmembers found the food stick valuable? Any comments on satisfying hunger, providing energy, ease of access?

The fruit bar mounted inside the suit was sometimes problematic because you couldn’t always get to it, but it’s nice to have something solid to eat.
7. **Please comment on the efficiency of the Urine Collection Device (UCD) during EVA? Was there irritation from the device which was exacerbated by movement in the suit?**

What we had was adequate, but you should continue to consider better ways to do it.

The condom catheter was undersized.

If there is a better system that is not gender specific, then we should consider it very seriously and test it to see if it will work in 1/6g.

The wicking diaper system does not work well in 1 g, but may possibly work well in weightlessness. If we can improve it significantly, then we should.

---

8. **Do you have suggestions for urine collection with frequent EVAs and mixed gender crews?**

See #7 above.

---

9. **Apollo 10: Crew was very concerned about voiding difficulties during time-critical ops. Crew suggested creating a device made of aluminum to plug into the suit to facilitate voiding with the suit on. In particular, a UCD that can be used with the suit on without having to zipper-down. What was this device, and was it ever developed?**

Were not aware that is was ever flight tested.
Apollo 10 was not normal!!

10. Was the Liquid Cooling Garment (LCG) wet at the end of an EVA? If so, where was it wet and did it cause any skin irritation through the comfort garment?

The air cooling systems were not adequate for more than an hour, however, there was very good cooling from liquid cooling, even to the point of overcooling if you let it run full up.

The liquid cooling garment was wet from sweat after each EVA and we let them air dry on our bodies.

*Post-Summit Questionnaire Responses*

No responses

11. Were you ever over-cooled by the LCG?

Yes, see #10 above.

*Post-Summit Questionnaire Responses*

No responses

12. Was the suit and helmet adequate in providing thermal protection? Were there any thermal cold or hot spots?

There were no hot spots, except on one occasion which was actually quite comfortable. When driving to the station, one crewmember stated his arm was in the sun for a significant period of time (30-40 minutes), heating tired arm muscles which felt quite therapeutic.

*Post-Summit Questionnaire Responses*

Suit was OK, helmet cooling from O2 flow was OK.

13. How strong was the concern regarding Decompression Sickness (DCS), or did you feel that it had been eliminated through design?

One crewmember questioned if there was only one case, if it wasn't another issue and whether it was misdiagnosed. However, in questioning the affected
crewmember, he absolutely felt it was DCS. He feels he is a "3-sigma" individual in his sensitivity to DCS. He bases his belief on an experience in an altitude chamber where he had pain in his left knee which spontaneously resolved upon repress. During his Gemini X mission he experienced pain in the same knee that was similar but more severe than what he experienced during the altitude chamber exposure. It started with capsule depress and went away over a period of several hours. Again in Apollo 11 on capsule depress he had a similar pain (location and character). It resolved spontaneously over several hours and was not severe enough to interfere with activities. He denies other episodes of knee pain during altitude exposure. He denies significant injury to this knee though he admits to numerous minimal sports injuries during his lifetime.

Crewmembers started prebreathe right away, as soon as the helmets were on.

Crewmembers suggested not only having low pressure in the suit, but also low pressure in the habitat. There would be many engineering and operational issues to consider.

You're going to have to bite the bullet and continue to use the PVS system and try to work at the lowest pressure possible to get the prebreath, to something that is inconsequential and somehow monitor the potential developing maximum levels. Take a hard look at whether you can gradually migrate back to PVS.

Post-Summit Questionnaire Responses

No responses

14. What were the contingency plans for any DCS symptoms?

We talked about this with the docs, and in general we did not worry about it because of the

100% oxygen environment of the LEM.

Post-Summit Questionnaire Responses

No responses

15. Any retrospective symptoms of DCS that may not be previously accounted for by suit fit pain or musculoskeletal strain?

In my aircraft, I quit prebreathing for well over an hour and I had some decompression as well. If you're going to launch with some nitrogen in your cabin, maybe you just have to extend the prebreathe.
**Post-Summit Questionnaire Responses**

No

16. Do you feel the pre-flight EVA exercise training program adequately prepared you for EVA, from an exercise capacity standpoint? How much more hand/arm exercise training would you have incorporated into your routine?

Yes in general it was adequate, however one area to improve both pre-flight and maybe on the way out is conditioning the forearms, esp. gripping.

**Post-Summit Questionnaire Responses**

Not on Gemini, but was in good shape for Apollo. Restraint systems in orbit a must.

17. Would you prefer one long EVA session, or two shorter sessions on a given day should the "work-efficiency" index be favorable? Ratio of: time of EVA/time of pre/post EVA activity) A break between EVAs would allow rest, hydration, food, replanning, etc. in the LSAM.

One long session would be the preferable way of operating, even if you're there longer than we were. Crewmembers preferred to keep going as long as the system would allow.

It's time-consuming to break the EVA up with a repress in the habitat, and then depress to go out again, including performing many checks.

**Post-Summit Questionnaire Responses**

Obvious

18. How many daily EVAs in a row, for a given set of crewmembers, would you feel be possible without undue physical stress or fatigue? (taking into consideration level of ambulation, task difficulty, etc)

Could do three days in a row but better to do every other day or two days in a row then off for one.

**Post-Summit Questionnaire Responses**
a. You mentioned that you had alternate EVA days. If there were 4
crewmembers available to go out, would it make more sense to have all
4 out on a given day and then a day off? Or 2 out one day and 2 out the
next day, so that you are doing continuous EVAs?

Although you should be flexible to be able to do one or the other depending on
the objectives, the preference would be to alternate 2 and 2. That would enable
mission control from the cabin during Mars expeditions. If you get used to doing
this on the moon, it will be easier on

Mars. Crewmembers could alternate every other day, then allow one day off
each week for whatever they want to do.

Keep in mind that a 6-month mission is very different than a 3-day mission. An
actual plan for a 45-day Mars surface stay has been developed and copies are
available. It should be left up to the real-time operational planning team, but if
everything is going nominally throughout the mission, then alternating EVAs and
teams will be an efficient way to operate.

Post-Summit Questionnaire Responses

No responses

b. So, there should not be an attempt to plan EVAs day after day, but leave
it up to real-time planning and some autonomy of decision-making
should be left to the crew?

Plan the operations on the surface so that you protect the crew from themselves.
The crews will work too hard to try to get everything done and they'll risk becoming
dehydrated and having serious physiological problems. Work out a schedule with
the crews ahead of time, but excessive workloads on consecutive days is going to
hurt somebody so leave some autonomy to the crews.

With extended ops on the moon, you should try to establish all the experiments in
the first week or so, and then allow the crew to just have a day to do R&R on the
surface, just for the sake of being on the moon and recharging their batteries, so
to speak. The schedule could be one day on and one day off, or two days on and
one day off, but guard against crewmembers overworking themselves. If you go
too long on a field exploration, you could be taking more risk than necessary.

You have to be careful with pre-launch activities, as well, to make sure
problems don’t exist when crewmembers launch.
Post-Summit Questionnaire Responses

No responses

19. What other suit changes would you advise to reduce workload, or mitigate injuries/strains, for the next generation suit not already discussed above?

Lighter, better gloves, more mobile.

Post-Summit Questionnaire Responses

Gloves, knees & in general better mobility

Our goal was to make the suit operation as autonomous as possible and providing confidence in its contingency capabilities. If we’re going to send folks out, we need to provide a modicum of protection against life threatening events, no matter how improbable.

- Rather than carry large quantities of O2 it would be worth exploring the ability to create a self sealing layer on the inside of the suit to stem the loss of pressure. It doesn’t have to be a perfect barrier, just enough to minimize the leakage due to minor punctures, leaks, cracks, etc.

- The most debilitating event can be one that allows the helmet to fog. It may be worth while to develop a way to periodically spray pure O2 on the front of the helmet, which can also reduce the local CO2 concentration during periods of exertion.

- The cooling system should also be self sealing with regard to leaks.

- Retain ability to make/break gas connection in a vacuum and provide contingency O2 on rovers, etc.

- Always use the buddy system when conducting an EVA.

a. One of the things we are struggling with for exploration is whether we should have one suit that can be reconfigured for different phases of the mission or do we go with two suits? Do you have any thoughts with your experience?

It depends on how the suit design turns out and if you can get in and out of it quickly. One crewmember commented that there should be only one suit. All operations should be performed in one suit that is easy to operate and flexible.

Post-Summit Questionnaire Responses

One suit if possible.
Lunar Surface Ops
Lunar Surface Ops

Dust

1. Describe any issues that arose due to lunar dust entry into the vehicle?

We dusted but there was still dust everywhere. It smelled like gunpowder, however you would get desensitized to it. Suits would have to be doffed before entering the vehicle.

*Post-Summit Questionnaire Responses*

Yes

2. Approximately how much lunar dust lingered inside the vehicle?

Dust is cleared rapidly in the cabin by lithium hydroxide. Dust is very abrasive and there are jagged fragments. The dust on the surface was a problem because it covered all your gear, visors, etc.

*Post-Summit Questionnaire Responses*

The ECLSS intake system that intakes and redistributes the air.

   a. A lot of the debriefs said that after they got back in microgravity that dust caused a lot of problems, so we are particularly looking at how the dust was cleared, symptoms, causes, etc. On some missions, the dust was like a cloud, but on others it was cleared fairly adequately by the lithium hydroxide ventilation system. We are curious why dust was a problem on some vehicles, but not on others. What were the differences in the ECLSS systems between the different vehicles, or is it a difference in volume, etc.?

The amount of dust that came back after landing should have been pretty consistent. Maybe some crewmembers cleaned more than others, or the ventilation system differed vehicle to vehicle.

*Post-Summit Questionnaire Responses*

Not so at all with the rover fender failure.

   A-16 lost a rover fender.
   So did Apollo 15.
   Apollo 17 lost one on the first EVA and it was repaired.
How about different landing locations with different characteristics. Vehicles were alike!

3. **Crews reported that they were quite dirty with lunar dust upon return to the LM. Dust was difficult to remove from any surface, particularly the hands and fingers. This contributed to getting dust in the eyes. Glove liners were not used on Apollo 11-13 mission, but were worn on subsequent missions. What type of material in the glove liner would best prevent the type of contamination you described? What other measures could be taken to protect the crew from dust contamination prior to doffing the suit?**

Lunar dust was embedded between skin and nail beds on all fingers. It was from handling rocks inside the lunar module. No glove liners on early missions, hard to get dust from under fingernails in those cases.

It took six weeks to grow out the lunar dust from the nails.

Beta cloth, fractured silica, and silk were mentioned as possible better materials for glove liners.

There are many reasons why you don’t want lunar dust in your equipment or anywhere else. Consider it from an engineering context, rather than the impact on humans. Take the angle of prevention.

*Post-Summit Questionnaire Responses*

No responses

4. **Did the inhaled lunar dust particles result in any specific symptoms (allergic reactions, sneezing, tearing, nasal irritation, coughing, sore throat, congestion, or other symptoms)?**

The dust smelled of gunpowder.

Helmets were not removed until the particles settled and went away.

There was dust in the mucous membranes of one crewmember that caused stuffiness and a changed voice, but it didn’t seem like dust produced an inherent problem.

The dust clears once it is in the environmental control systems.

No medications were used for symptoms, but today Claritin could be taken.

We had bigger problems with fiberglass irritation.

Studies are being conducted on silicosis and this is important work.
Post-Summit Questionnaire Responses

What is this fiberglass problem? Law suit pending.

5. If you experienced inhalation irritation from exposure to lunar dust particles, how long did these effects last? If you put on a mask to reduce the irritation, how long did it take for symptoms to disappear? Did the irritation cause any decrement in your ability to perform tasks?

Sinus problems went away after the third EVA, so it wasn't a major issue.

This was contradicted in the following statement: During sampling for the microbiology program, exposure to lunar dust from the suits caused a reaction that worsened with each of the 3 sampling periods. The first exposure caused a stuffy nose and watery eyes. Lab results showed about 5% eosinophilias and a couple basophilia. On the second exposure, there were more symptoms of watery eyes and stuffy nose. Eosinophilias went up to 9% and there were some basophiles. On the third exposure, it was impossible to stay inside the spacecraft long enough to get the sample due to extremely watery eyes. In order to get the sample, it was necessary to get out, take a deep breath, then return to get the sample. Again, there was a 9% eosinophilia and 5% basophilia. Others performed the same function after the return of other missions and had no reaction.

Dr. Jones stated that it was interesting that it didn't passivate during the transport. There will obviously be individual variation in the response and we may have to do susceptibility testing before flight.

Post-Summit Questionnaire Responses

What the hell!!

6. What skin effects were caused by lunar dust? Specifically, was there any redness of skin, itching or any other specific symptoms that you can recall?

None.

Post-Summit Questionnaire Responses

Yes
7. **What eye irritation did you experience? Specifically, was there any redness of eyes, itching or any other specific symptoms that you can recall?**

Not any significant, did get some in eyes, but more of a nuisance. Put suits back on in one flight to prevent breathing the dust. One CDR wouldn't let dusty suits into CM until bagged, due to dust.

*Post-Summit Questionnaire Responses*

Yes. Why do CDR get the credit - when CMP did it! A-12

8. **Were dermal and ocular effects lasting? If so, for how long; and did this cause any decrement in ability to perform tasks?**

No. As far as prolonged exposure to lunar dust, experimentation on Earth will not resemble the in situ properties of lunar dust, so we have to be careful about the conclusions we draw. We need to work from an engineering point of view to develop a layer of defense. Engineering actually worked pretty well on Apollo, whether advertently or inadvertently. The bearings on the lunar rover showed no symptoms on any of the missions.

Although it doesn't seem to have had an effect on the crewmembers, we had very limited exposure. Chronic exposure is very different than short-term exposure.

The lithium hydroxide filters seemed to pick up the dust fairly quickly. If you think it's important, the lithium hydroxide canisters in the CSMs could be analyzed to see how much actually got in the cabin. The sub-micron sized particles may be most worrisome physiologically for humans, but it is really unknown.

There needs to be a layer of defense to protect not only the crew, but also the equipment. The EVA suits may be used hundreds of times and dust will be a major factor in that. We saw dust scratches on our neck and wrist rings. It is extraordinarily penetrating dust.

There were differences in the landing sites relative to the nature of the dust, but it is unknown whether there are significant differences from a physiological standpoint.

*Post-Summit Questionnaire Responses*

No responses

**Surface Tasks**
1. Apollo 12: The CDR/LMP stated the shadow pattern over the terrain/crater edges gave the illusion that the slope was much steeper than it actually was.

Reflective light in the shadows isn't as evident as on earth. Craters did appear steeper visually. We knew we had to go down into that crater, so it gave us concern.

There is a general visual phenomenon, there isn't good reference for your eyes and the estimation of distance is off. All sorts of ambiguities on the moon (i.e., slopes, terrains, sun shadows, bland environment). No environmental references like on the Earth (i.e., trees, houses, poles).

A comment was made regarding the length of a crewmembers shadow because it always looked shorter and it was needed as a reference. The shadow was calculated prior to the EVAs and could be used as a baseline. After a period of time adjustment does occur.

*Post-Summit Questionnaire Responses*

No responses

a. What is the steepest incline you tried to navigate?

The steepest incline encountered was a 20-26 degree slope. If it was steeper, we would not have made an attempt.

The degree you could operate at safely depends on the task. It is easier to decide to go up a hill, because it is more difficult cooling down.

There was concern for falling down slopes. Also if went down a steep slope, you couldn't be sure that you could get back up.

*Post-Summit Questionnaire Responses*

No responses

b. If there was a lighter suit, would you feel safer or be able to go up a higher slope?

It was coming down that was a situation to be more cautious.

*Post-Summit Questionnaire Responses*

No responses
2. How did the crew negotiate descending down the craters with this illusion, did it really cause a problem or was it an interesting observation?

See #1 above.

Post-Summit Questionnaire Responses

No Responses

3. If it was a potential problem navigating the lunar surface, what would be the recommendation for eliminating this problem for future crews?

Can always follow your tracks back to the habitat. INS possibly.

Post-Summit Questionnaire Responses

No Responses

4. During the lunar EVA, the crews often worked harder during “rest” periods (as evidenced by heart rate data) than during work periods. However, the crew did not feel this level of physical activity pushed them to their exercise capacity limits.

Many crews worked as hard or harder during rest periods because that was our time to catch up. The EVAs always had more scheduled than you could do in the time allotted.

Didn't have time to rest. Recommend doing EVA for 2 days then rest the third, so don't make fatigue mistakes.

EVA is not as safe if you are mentally fatigued.

Post-Summit Questionnaire Responses

Yes. Unless looking for an intervelometer.

Heart rate is not a reliable indication of work load.

5. Although the crews did not report feeling physically challenged during the lunar EVAs, can you offer any insights on how you might have felt carrying out this surface activity timeline over the course of 7-14-30 days?

The most important issue is to get enough rest. If you fall behind in your sleep, there is potential trouble.

It is difficult to sleep, you doze and the adrenalin is pumping too much to sleep heavily.
Several crewmembers worked a 30-hour day. As long as the crew is given time of their own, that is the main issue, and they can use it as deemed necessary whether it is sleep or not. Sleep is an individual thing.

Privacy is needed for sleep. Crewmembers get comfortable when adapted.

Circadian rhythm was not important on the moon.

Mental and physical rest plans should be introduced. Should have planned breaks and rotations, maybe alternating flight crews and plans.

*Post-Summit Questionnaire Responses*

RG: Yes

6. **How do you feel the pre-flight EVA training program prepared you for lunar EVA?**

The POGO and centrifuge training were beneficial. There is no special training needed for 1/6 g EVAs.

Adaptation occurs quickly regardless, You learned your limitations.

You did as much as you could to get in shape. ALSEP training in 1-g was excellent. 0-g training was more important than 1/6 g. Only need a 1/6-g fam session.

*Post-Summit Questionnaire Responses*

No Responses

7. **What would you do differently in your training for these longer surface sorties?**

There may be more tasks you need to train for. Task-specific training for specialized operations is optimal.

Mission focus should be project-oriented and not timelined. The crew needs to have more freedom. Leave time for unexpected activities.

*Post-Summit Questionnaire Responses*

No Responses
8. What does the crew consider were risky tasks during LEVA?

Puncturing the suit was considered the biggest risk. Even though it was puncture safe, it was still a concern in a new environment. If a suit actually got penetrated, look into something that causes a self-seal. Self-seals are used in the military.

The only other concern was if your zipper was not working, broken, leaking, etc.

Another concern was hand fatigue. Some experiments could have been deployed robotically.

Post-Summit Questionnaire Responses

Yes

a. What activities had the highest risk of falls/injuries?

Going down slopes, esp. if carrying heavy objects, possibly driving rover on sloped terrain.

Post-Summit Questionnaire Responses

No Responses

b. Discuss any particular muscoskeletal strains...back, abdomen, legs...related to falls or slips.

Note: Apollo 12: Visual spatial distortions/disorientation due to certain sun angles on sloping terrain

Apollo 15: Drilling for core samples and establishing a port for heat flow experiment at the end of EVA #3

Apollo 15: CDR deciding not to wear seat belt on rover to save transit time back to LM at the end of EVA #2

In the video, it was obviously taking energy and this all starts from the pre-mission decision that at this particular station, one crewmember was to do some individual sampling while the other crewmember performed some necessary housekeeping at the Rover.

Because my hands were tired and because I didn't have a good sense of how much pressure was putting on the bag, I dropped the bag. So, I was in the process of trying to first of all recover the samples that fell out of the bag and a number of things. This was just a whole set of bad decisions in pre-flight planning, as well as in operations, and I hope that with that kind of experience we will never do that again.
Post-Summit Questionnaire Responses

No Responses

c. Along the same token, you said that none of these falls really caused any significant strain, impact, injury?

No, the main consequence was that you got dirtier than you should have.

Over time, you could see the dust migrate up the suit.

In terms of hazard, you're falling as if you're only 1/6 your height, so you don't hit very hard and you're in an extremely strong suit.

Post-Summit Questionnaire Responses

No Responses

d. So, when you fell, did it hurt at all

No, due to the rugged suit we were in, if had a lighter or more flexible suit then maybe.

Post-Summit Questionnaire Responses

No Responses

e. One of the things that we need to be careful of as we do this testing on the ground with the POGO system, our center of mass is moving at 160, but we're in the suit under 1 g, so our impression of a fall under those conditions is probably different in reality?

Yes, and you have to take into account the workloads. You're still moving in a 1 g field, so you're doing 1 g work with your arms and legs.

Tests are being conducted in the KC135 with a 1/6 parabola to obtain quantitative net rate versus speed.

Post-Summit Questionnaire Responses
Yes. But be careful - you always start from a stable position.

9. Does single-man parallel ops over 2-man teamed ops for deploying experiments and equipment reduce the risk for falls or other potential injuries?

Never felt physically at risk. The configuration for deploying the experiments is not a factor.

Post-Summff Questionnaire Responses

No Responses

a. Is it safer to operate tools independently or with another person?

Do not send one person out alone unless it's an emergency or mandatory.

Post-Summit Questionnaire Responses

No Responses

10. From a crew performance standpoint, with consecutive daily lunar surface EVAs being considered, is there a better time during the crew day to schedule these events?

The EVAs should be based on the sun availability. It gets hotter at high noon due to the sun. OK to do EVA in Earthshine periods, light is adequate.

Post-Summit Questionnaire Responses

How do they know?

11. In terms of reducing crew physical workload would a robotic "companion" on EVAs have proved useful or more cumbersome? What about a low tech walking golf cart solution? Could robotics reduce your workload or reduce fatigue?

A robot should perform routine, systematic, repetitive, menial tasks. This will free the crewmember for other tasks.

Post-Summit Questionnaire Responses

No Responses
12. What was the impact of lunar dust? How much was "tracked in" on the suits during lunar EVA and what impact did it have on vehicle systems and crew health?

See dust issues above.

*Post-Summit Questionnaire Responses*

No Responses

13. What part of the lunar surface EVA caused you to expend the most energy? Metabolic studies seem to point to the last 30 minutes of the EVA, where the crew was ingressing the vehicle. Do you believe this contributed to fatigue and was there a risk of injury?

The hatch should be made where you can go straight in. Make so you don't have to arch your back and tilt the backpack in order to get back in. It's a volume configuration issue.

The risk is death if you can't get back in.

*Post-Summit Questionnaire Responses*

No Responses

14. What was your optimal speed on the surface above a brisk walk?

Half again as fast was average speed. Routinely measured at 6 kilometers an hour.

Can lope quicker on the moon than briskly walk on Earth. Up to 10 km for an hour.

*Post-Summit Questionnaire Responses*

No Responses

a. You also mentioned that you would like to see suit recharge capability on the Rover?

In future Rovers, you should have the ability to recharge your suit or at least live off of Rover consumables when you're driving or working around it. This will require a change in engineering, as well as a change in mission rule. It will be a design challenge, particularly in that dust environment.
And it wouldn’t be just the Rover, there may be other activities, particularly when you get to a lunar base phase, where you’re going to be doing things outside, but in a fairly fixed position near the base/habitat. You will have to live off of a different set of consumables.

It’s one way to reduce the mass of the suit. It’s also a way to extend the duration of your activities.

Another advantage is that if you decide that you’re going to protect yourself against a solar particle event while you’re some distance away from any pre-positioned shelter and you’re going to use some method of excavating a trench to reduce the exposure envelope as well as possibly even live underneath the Rover for a few hours as additional protection, then you would like to have an extension of your consumable supply.

Post-Summit Questionnaire Responses

Yes. Not a bad idea.

b. We also discussed that you thought it would be acceptable to have a deployable shield for radiation protection on the Rover?

You should certainly do some conceptual designs and determine the consequences. There may be unintended consequences terms of CG, rollover, etc.

Post-Summit Questionnaire Responses

Roll the dice.

c. Comment on driving the lunar Rover in your suits. How comfortable was that? It often looked precarious when going up and down on the lunar surface.

It was very comfortable driving in the suits.

The wrist motion was very good. You’d just rest your hand on the controller and you could move it and guide the Rover very well. It was a very effective transportation system and was easy to use.

There is a problem with visibility on the moon because when you’re driving down sun you have no shadow definitions and you have to adjust either your speed or move in a zigzag pattern to avoid a hazard.

The one thing we would have liked to have is some kind of an automatic position determination so that you could save time looking for where you were actually trying to go. We spent quite a bit of time trying to find the right crater patterns.
With a GPS system available, we would have saved some time.

*Post-Summit Questionnaire Responses*

No Responses

d. **How long could you maintain your pace? What would you modify on the flight plan?**

Work two days, then rest on the third day. When fatigued, you make mistakes and are not as safe as you think you are.

Take a day off after EVA and get your suits prepared for the next EVA.

Come up with a formula to give people mental as well as physical relief. You can maintain this effort for short periods of time, but not for extended timelines. There are good operational reasons for having people alternate EVAs. there are several things to be done on a day off, flight planning, etc, not necessarily a true day off.

*Post-Summit Questionnaire Responses*

- Perhaps the most important recommendation would be to stop trying to maximize every minute of surface time with pre-planned timelines, etc.
- The ISS folks seem to have learned this
- If you want to explore, let the probers pick their own pace and focus.
- The next set of missions should not be short sorties, but part of an ongoing program.

e. **If the ladder from the habitat were higher, would you have concerns?**

Would make the ladder wider, possibly with a rail.

*Post-Summit Questionnaire Responses*

No Responses
In-flight Illnesses
In-flight Illnesses

Space Motion Sickness and Entry 'Sickness' and Disorientation

1. How strong were your symptoms and were they still present during transfer to the lunar surface?

Symptoms were felt the first day, however it is individualistic. (One crewmember commented that in his experience approximately 1/3 to 1/2 of the crewmembers experienced symptoms.)

Space motion and space adaptation are two different things.

Crewmembers worked through the symptoms and felt that it did not impair their work performance.

Most of the symptoms are gone within a couple of days and crewmembers felt adapted to the new environment.

Preflight measures were not taken to prevent Space Adaptation Syndrome. (There was a recommendation to consider pressure points.)

Crewmembers took preflight measures by flying T-38s, but it is unclear whether this helped or not.

There were no reports of problems during Mercury or Gemini, but it may be that they just didn't mention it to the flight surgeons.

Many countermeasure were considered. Flying was one method.

There was probably still some stomach awareness, however.

During Gemini, felt "punk" for 24 hours, that is "didn't feel like going dancing".

Early Apollo only felt punk 2-3 hours, but late Apollo it was gone after an hour.

Post-Summit Questionnaire Responses

Fluid shifts to head almost immediately upon arrival on orbit. Found that sinuses tended to stop frequently and sometimes for prolonged duration. Annoying only. During Shuttle, we noticed that five minutes on the treadmill would immediately clear the sinus.

a. Can we do anything to use other countermeasures effectively?
Since symptoms decrease with subsequent missions, it may be advisable to fly crewmembers with previous microgravity experience. However, there is some contradiction in the following crewmember comments:

- "On early flights I had a great time, but later on I got very sick."
- "Same for me...symptoms came later with training cycles. Not sure why."
- "It luckily didn’t happen to me. It's individual. There must be a way, through history, to get a getter definition of this problem."
- "I've never experienced motion sickness in my life."

*Post-Summit Questionnaire Responses*

Yes. Find a way to predict.

2. Did you notice 'vertigo' or disequilibrium during LEM ops and post landing on the moon? Comment specifically on accomplishing tasks in the LM during entry and landing, and accomplishing tasks in the immediate post landing period on the moon. Comment specifically on accomplishing tasks in the LM during entry and landing on moon symptoms.

See response to questions 11, above, Ambulation and CG issue above

One crewmember stated that it is a function of the inner ear or it could be the emotional state.

"It may be a psychological thing."

*Post-Summit Questionnaire Responses*

Yes

3. How would you compare your 'stability' while walking in 1/6 g vs return to Earth and 1 g?

Easier to ambulate at 1/6 g, it is wonderful. We need a little time to get our sea legs when got back, otherwise no real issue.

*Post-Summit Questionnaire Responses*

No Responses

4. Some crew found transferring from CM to LM disorientating, and reported that it may have contributed to SMS. Are there any orientation cues or suggestions in the design of the two vehicles that may help minimize or ameliorate this disorientation? Given the current architecture for the CEV LSAM, how could your suggestions be implemented?
Post-Summit Questionnaire Responses

Don't worry about it.

Practice in the KC-135 or C-9 in zero g in the CM to LM simulators

Yes, slightly disorienting -but not the source of SMS. Just interesting. Perhaps have a training setup where transfer can be done, even unsuited. In Apollo we had no such device -on CM or LM, but not combined. Therefore it was mostly unfamiliarity with what's where.

We did not have a problem with this issue. I think the answer is "Believe Your Eyes" and don't move fast, especially your head. Training issue!

Find crews that orient by sight not by mental gymnastics.

Back Pain

1. Crew described significant back pain during the first couple of days of the mission. To the best of your memory, can you describe the back pain in terms of location, character, intensity, exacerbating and alleviating position or exercise most effectively relieved the pain?

One crewmember commented that his back never felt better than it did in 0 g and he never used the fetal position as a therapeutic technique.

The Exer-Genie was used for deconditioning. "It was also nice for the spirit and a good way to relax."

Back pain may be related to elongation of the spine, but this is not yet clear.

Back problems were not necessarily discussed with Flight Medicine because Apollo crewmembers thought it was due to sleeping problems.

However Dr. Ross stated that several Apollo crewmembers did complain of low-grade, chronic back pain. The problems were non-disk related. Some crewmembers improved, however some did not. Massage and exercise helped alleviate the pain somewhat, as well as getting into a fetal position.

Military history was also a consideration. Some crewmembers had problems from low back to cervical spine, including injuries. 90% are lumbar spine problems that seem to be related to piloting high-performance jet aircraft. It is important to discuss this with consultants that can provide the correct types of therapy.

It could be that back pain is not "space normal" and we need to determine what we can do about it.

Post-Summit Questionnaire Responses
I don't believe lower back pain is due to military/jet experience. I think it is related to offloading of upper body weight. Lower back definitely went into spasms. Fetal position felt good but may not be good therapy.

Yes.

2. **Considering the configuration and constraints of the CEV (e.g., 5.0 cu³ volume) compared to the Apollo CM, how would you advise the crew/engineers to design the couches/exercise equipment, sleep compartments or restraints to help minimize back pain symptoms?**

Strengthen the abdominal muscles to prevent back pain. Doing lots of sit-ups seems to help. Develop preflight exercise protocols. "Low back pain cannot be designed out, take Motrin and go on."

The ASCR program can lessen the risk of injury. The ASCRs are very aware of these problems and are paying attention to this with preventive measures. Core strengthening pre-and in-flight helps. This will be used for long-duration flight. Creativity will be necessary for implementing the program in a constrained environment. The Exer-Genie was the only piece of hardware in Apollo. It had problems due to heat build-up in the rope during use.

The crewmembers considered it a threat if heat built up after too much use.

Examine the spacecraft to determine what can be worked with or against to get the proper exercise. Dr. Ross reported that a multi-disciplinary approach is being taken to work on training and preflight injuries/anomalies for prevention rather than cure. This includes engineers, astronauts, suit techs, ASCRs, etc.

*Post-Summit Questionnaire Responses*

The Exer-Genie did not work. Call me for a detailed explanation.

No. The Exer-Genie was misused. It is isometric not dynamic - no heat should be present.

3. **Did the CDR/LMP experience any low back pain on the lunar surface? Were there any positions or exercises that the crew performed that improved their symptoms? If so, what were they?**

*Post-Summit Questionnaire Responses*

Not me.
Eye Irritation

1. Apollo 10: Conjunctival irritation occurred in the CM secondary to fiberglass in the cabin. Required the crew to use saline eye drops. Source of the fiberglass or circumstances not explained in the debrief. What was the source of the fiberglass in the cabin? Was the eye irrigation system adequate to clear the irritation?

Fiberglass irritation was mentioned above, however crewmembers did not elaborate.

Post-Summit Questionnaire Responses

Not on our flight

Was there fiberglass present?

Joint Pain

1. The Apollo 11 CMP described onset of left line pain after launch, similar to that experienced on Gemini X and in altitude chamber testing. The cabin atmosphere and oxygen concentration being considered for CEV/LSAM/Lunar habitat will involve a gradual decompression, although the exact AP is still under debate. Although the CMP’s symptoms were not attributed to dysbarism by the flight surgeons, it is certainly suggestive of this condition. Can the CMP describe in detail the symptoms and events surrounding his joint pain. What recommendations can the crew offer for the atmospheric parameters being considered to CEV/LSAM?

See EVA q. 13.

Post-Summit Questionnaire Responses

I have listened carefully & still believe my symptoms indicate nitrogen in left knee. No problem for me.

Sleep

1. Did the coronal discharges interfere with sleep i.e., sleep onset, efficiency, etc? Was there a particular mission phase that the discharges were more noticeable?

Noticed flashes more when closed eyes, before went to sleep.

Post-Summit Questionnaire Responses

We did an experiment for flashes. Did not interfere with sleep.
Find a way to make taking sleeping pills not a sign of weakness in an astronaut's mind. A sleeping pill should be thought of as a chemical tool.
Yes. No effect at the time?

Musculoskeletal Injuries

1. What injuries or aches and pains were most common following EVA? How could you reduce the likelihood of injury?

Soreness in the forearms was the most common, but usually was better by the next day.

Post-Summit Questionnaire Responses
No responses

2. How did you 'rehab' or recover from injuries? What preflight preparation reduced these symptoms? Did any injuries interfere with task performance? What injuries and aches and pains were unexpected?

Post-Summit Questionnaire Responses
Had wrist ring cut on right wrist to bone – used no fix until return.
No injuries.
None

3. On the lunar surface, did you ever experience a fall that produced a 'hard' landing? Did equipment ever fall on you?

No. Falls on the lunar surface were "gentle."

There was little concern for injury except falling onto a piece of equipment or breaking your visor.

Post-Summit Questionnaire Responses
No responses

4. We hope to design out, as much as possible, risk of trauma and injury, so that we can reduce the potential need for acute medical care. For example, better suit design could reduce the likelihood of shoulder and hand injuries. Do you have any suggestions for how we might do this, and what hardware and tasks might be redesigned to reduce these risks?
Post-Summit Questionnaire Responses

Fit the suit to the person - new gloves that incorporate mechanical closure for gripping without fatigue.
Better glove design - squeeze more tennis balls?
Suits much more critical for extended stay on surface.
Better suit design but also design exercises that strengthen muscle & joints effected

5. Did the design of spacesuits for lunar work allow you easy movement, or was it difficult to maneuver?. Did these difficulties contribute, in your opinion, to susceptibility to falls while working on the lunar surface?

A lighter suit would reduce the inertia for movement and make it easier to stand-up.

Post-Summit Questionnaire Responses

The UCD was only used for EVA; operations on the lunar surface, etc. The CM was equipped with a relief tube. XXXX did wear his UCD on 13 and it resulted in a urinary infection. For EVA operations I don’t see how you can improve the device.
Medical Kit
Medical Kit

1. **Considering the configuration and constraints of the CEV, do you think you could reconstitute a drug in that environment? In other words, if the drug was in a powder format, could you reconstitute it into a solution using normal saline or another diluent that would be provided in the kit?**

   This should not be a problem in microgravity and certainly not on the lunar surface.

   *Post-Summit Questionnaire Responses*

   Would be okay if the way was to add water.

   Yes.

2. **You mentioned in debriefs that blister packs were an issue because they expand during depressurization. We currently use pill bottles and Ziploc bags to pack medications into the current generation of kits. Using your experience and knowledge from Apollo, is there anything we would take into consideration with the design of the next generation of kits given the space in the CEV?**

   Provide items that are needed in daily life, such as lotions, bandaids for minor abrasions, Tylenol, mild sleeping pills, etc.

   Having a physician crewmember would increase the comfort level.

   "Always have a doctor." cross train physicians to perform other activities on the mission.

   "Cross train fighter pilot to be a geologist on the moon."

   *Post-Summit Questionnaire Responses*

   Yes.

   **a. The kits for Apollo were very small and basic. What is your impression of the new kits today?**

   An example was shown and a crewmember commented on the large size and inquired about the contents. Dr. Jones stated that it contains blood pressure equipment, diagnostic capability, etc. More capability planned for the lunar kit to deal with contingencies.
Thought should be adequate.

*Post-Summit Questionnaire Responses*

Did not see it.

There is no question that a medicine to combat fatigue should be on board spacecraft. We took Dexedrine just before reentering the atmosphere to make sure its effect would stay with us throughout the landing. Take the medicine too early and their effectiveness would end and increase the fatigue. We were asked to take Dexedrine to combat fatigue. I did not because I was worried about a crash that might come when it wore off. It frankly was not necessary as the excitement of the upcoming entry and stress of the CM power up generated a lot of adrenalin. So I was very alert for that final entry phase of the Mission without any drug boost.
Bioinstrumentation
Bioinstrumentation

1. Do you have any suggestions as to how we could improve the means by which we monitor (Heart Rate, metabolic rate) astronauts on the lunar surface, given our current system is almost identical to what you used in Apollo?

Wrist pulse monitors would be helpful. It would be good to have facilities for the crew to be healthy and well, especially if a physician crewmember is not a member of the crew. This would allow monitoring from the ground.

The Heads Up Display (HUD) can overload people. It is not necessary crewmembers' blood pressure, etc. The displays should be simplified. consumables information and rate of use is okay. For other non-critical data, let a Caution and Warning bell ring, then check it out.

*Post-Summit Questionnaire Responses*

Yes. In addition to monitoring how about treatment.

2. Upon reviewing the lunar surface films from the archives, it can be seen that the abilities to ambulate and perform tasks were a human factors challenge. In many instances you had to slow down due to physical exertion required for the tasks. Surgeon and Biomedical Consoles monitored this activity to help forecast consumables and overall stress on the crew. Given the advances in technology over the last 40 years, do you believe that if you were given accurate metabolic rate information and suit consumable data, that future astronauts would be able to "self regulate" their EVA activities in an autonomous fashion?

Yes this could help for missions on Mars.

*Post-Summit Questionnaire Responses*

Yes

3. There were several times the suit Caution and Warning system notified astronauts that they were exceeding the thermal transfer capacity of the suit cooling system. During many of those times we did not see an excessive heart rate. The crew medical debriefs did not discuss this detail in depth since it was mostly a suit ECLSS issue. Do you recall anytime when you were really tired and the suit C+W was nominal or any circumstances when the C+W had a temperature warning and you were not tired?
Post-Summit Questionnaire Responses

No, was never "very tired."
No., never happened to me.
Not on my suit Apollo 12
Environmental Impacts
Environmental Impacts

Environment and Habitability

1. Temperature
   a. How comfortable was cabin temperature in the CM and the LM? Cold, warm, OK, or depends on mission phase?

      The temperature was comfortable and never seemed to be an issue during Apollo missions. Crewmembers slept in the LCGs and didn't use a cover. It was more difficult during Gemini "because it was way too hot".

   Post-Summit Questionnaire Responses

     Yes. It was okay.
     Yes. Way too hot? Not a concern.

     The temperature was well balanced in the CM utilizing heat from the electronic systems and dissipating excess heat by a radiator. On 13, however, with most of the electrical systems shut down, we were losing heat faster than the sun could provide. The temperature gradually dropped to about 34°F by the time we reentered the atmosphere. We could have put on our pressure suits but they were too bulky for three men in the LM. It appears shuttle crews operate in-flight in shorts and tee shirt. If that will be the uniform on lunar flights, I suggest some thermal protection in case of electrical failure.

   b. What was the temperature control like in the CM while in the suits at vacuum on the suit loop?

      It was fine. The biggest temperature concern was staying cool and not getting sick before getting picked up at landing.

      On the lunar surface, the suits were very uncomfortable and should have been removed to get some rest. This could have jeopardized the mission.

      Be careful trying to design for the exceptional circumstance, need to train well enough to be able to react to the situation.

   Post-Summit Questionnaire Responses

     Yes. Okay
     Yes. What is this getting sick?
c. Would thermal protective clothing have been adequate?

Yes, you should consider what is already onboard, maybe simply a thermal blanket. If the suit was easier to get on, it wouldn't have been an issue.

Some crewmembers stated that they wish they had taken the time to unstow the suits.

Post-Summit Questionnaire Responses

Yes

One can certainly design for improved sound suppression and add thermal blankets that would support an emergency power down such as we had on Apollo 13. The issue is added weight. That would have to be a part of a design trade study. Trying to provide comfort like at home and handling extreme emergencies might compromise accomplishing the basic mission because of weight growth.

2. Waste Management

a. Did you have any experience in the development of the "fecal canister" in the CM and do you know why it was never flown?

It worked fine, however it could have been a little bigger.

Diarrhea needs to be prevented in 0 g to eliminate mess and time-consuming cleanup. Systems should be designed differently for 0 g versus positive gravity.

First determine what should be used on the moon, then work on the vehicle.

Post-Summit Questionnaire Responses

No.

No. There was no fecal canister--just bags.

b. The urine collection device caused problems on virtually every mission. What specific problems did you encounter?, What are your recommendations for improving the device for CEV/LSAM waste management systems?

There were no problems with the UCD, however you want to sit on the moon not strap a bag to you. Have to know not going to move bowels on EVAs. Dr. Kerwin suggested using the Skylab system, since it worked great in 0g and in 1/6 g it doesn't need airflow. Problem solved! All participants concurred. System must be customized for both men and women. Diaper is good for urine during EVAs, however cannot defecate in EVA suit.
Apollo 8 did a urine dump and it turned into snow. It was a navigation issue.

"The Agency is trying to make everything perfect." It is not possible to think of everything that may go wrong. "Crewmembers are willing to suffer under certain circumstances."

Post-Summit Questionnaire Responses
Yes. Did not have a problem Yes. Don't poop!!

c. Was it acceptable to have a bag for outbound and return, as long as there was no "off-nominal output"?

Off nominal output was dominated by surface tension. It adhered and moved. Fix it!

Post-Summit Questionnaire Responses
No Responses

d. Waste management issues dominated much of the debriefs. The crews reported that they felt it “uncivilized”. Although it depends on the crew, some crewmembers stated that they considered themselves explorers and felt they could put up with anything. That might be why some debriefs did not have complaints. You can put up with anything for two weeks, but it would be different on very long-duration missions. What can we do better, other than make the bag bigger?. We know mixed crews will also complicate things.

Calcium balance studies were being done that required crewmembers to collect waste.

Don't make it a requirement to save it, just dispose of it all, including the blue bag.

Everything would be fine if crewmembers had the time to do it, could clean it up, and didn’t have to save it.

Post-Summit Questionnaire Responses
Yes. Not a big problem. Dispose of collection bag before entry. Yes. Uncivilized? What the hell is this!! Take them camping in the woods for a few weeks!! Wimps need not apply
e. Do you feel a need to separate your area for food preparation (galley) from waste management? It was designed to take up limited space. What should be done about this?

The crewmembers felt there was no choice in this situation.

Post-Summit Questionnaire Responses

No. Nothing

Space limits dictate. We can live with that.

Yes. Separate for the weak of heart.

Noise/Acoustics

1. Noise level in the CM was unacceptably loud, interfering with sleep periods. What mechanical systems were responsible for the noise (e.g. cabin fans, glycol pumps)?

Inverters were noisy, but a pleasant sound because it meant everything was working. Earplugs worked. High screeching noises were unacceptable.

Crewmembers didn't seem to be too concerned with the noise and stated that it did not keep them awake. The absence of sound would have been more uncomfortable.

Minimize noise, but don't eliminate it. There are noise-canceling devices today.

Post-Summit Questionnaire Responses

No. I liked the background noise for sleeping.

Yes. White noise is good.

I personally was not bothered by the noise level in the CM on 8 and the CM was shut down on 13. It seems to me, the orbiters being much larger than the CM the noise levels should be lower. On Apollo, we had ear plugs for communications and were helpful in reducing noise to the ear.

a. Was there a threat to hearing?

No, there was not enough sound to threaten hearing. The iPods are a concern now, but didn't exist on Apollo.
Post-Summit Questionnaire Responses

Yes.

2. Was hearing protection or noise attenuating devices available for the crew? Did they work adequately?

Post-Summit Questionnaire Responses

Had none. Needed none. (Maybe that's why I'm deaf now.)
No.(no hearing protection was used)
We had the Snoopy earphone caps -I never was bothered by noise.
Don't think so, but would not use anyway.
Not available. Not needed

Sleep

1. Some crew preferred being wedged into something to feel secure for sleep. The sleep restraint system was outstanding. How can these important considerations be incorporated into the CEV/LSAM design, based on your experience in the CM/LM?

There is good technology today. No reason to re-invent the wheel."

After approximately 3-4 nights of adaptation and excitement, gave in and went to sleep.

Pillows and comfort items are important.

Sleeping in the hammock was comfortable, although frequently awoke to check things. 1/6g solves problems.

Post-Summit Questionnaire Responses

No. Used hammock for about 3 days, then did not bother with it. Slept mostly in couch after that.
Yes
The sleep restraint system worked fine in Apollo and I suspect they worked just as well in the orbiters. For lunar surface, hammocks could be rigged in the LM. You will have to ask others on how good they were.
a. Are there any other comments about sleep, besides the ones discussed above?

One crewmember reported a loss of proprioceptive that kept him from going to sleep in the first rest period after launch. He realized he could not feel where his arms and legs were and how much muscle tension it took to get them back. This only occurred during the first sleep period and he never noticed it again after that.

That first half hour rest period was a "fascinating experience".

Another crewmember stated that using the restroom at night always woke up other crewmembers.

Post-Summit Questionnaire Responses

Fetal position felt good for sleep but the sleeping bag allowed only one knee to be raised at a time. (1) Make sleeping bag large enough to get both knees up, (2) Provide strap to hold knees up. As I drifted off to sleep, I would release my knee & it would wake up.

Yes

Air/Atmosphere

1. The lunar crews stated the moon dust had a distinct "wet ashes or gunpowder" odor upon return to the LM. Were these odors/fumes noxious, i.e., did the crew experience any reactions to this odor?. Was it cleared by the LM ventilation? Were there other sources of dust and particulates in the CM or LM? Was lunar dust noticeable in the CM?

See dust issues above.

Post-Summit Questionnaire Responses

Yes

a. Were there any problems with air or water quality? Was there a need for point-of-use filtering or biocide? For air contaminants, what would you recommend that we monitor for?

CO2 levels should be monitored in the air.

Chlorine in the water was an issue during one early Apollo mission, however it was resolved in later missions.

Crewmembers didn't notice a problem with the water if it was mixed with food. Chlorination and ionization technologies should be reviewed for future missions.
Gas-permeable bags had bubbles, but this has been resolved.

Chlorination is not an issue now. Information can be obtained from the debriefs.

The crewmembers reported headaches and wondered if they were caused by CO2.

Post-Summit Questionnaire Responses

CO2 most important.
Yes.

b. Were CO2 measurements reliable?

CO2 monitoring was unreliable and the readings were no good.

Post-Summit Questionnaire Responses

No. Didn't know this!!
Microbial
A discussion was held regarding the build up of microbials in closed vehicles and how this would be managed. Topical wound care treatments, such as Neosporin, should not be used routinely, but only for high-risk wounds that are at risk for infection. There may be changes in wound healing during space flight, so it is not yet known how this will be handled for future exploration. Topicals were more resistant to loss of potency. This is a big issue for long-duration space flight. Topicals will be available, but not necessarily used for routine wounds.

It is not known if antibiotics will remain active and useful in space. One audience member commented that it may be like "Civil War" medicine without antibiotics. If one crewmember had an organism, all the others would get it.

Dr. Fischer stated that we don’t know how absorption occurs during space flight. This is a major issue that needs to be addressed. Dr. Jones stated, however, that there have been some cases of in-flight infections that have been successfully treated with the medications flown. There is more capability now and prevention is the best approach. A different design is needed for urine collection.

Stowage/Layout

1. In emergency suit donning cases such as cabin depress, was there adequate time to allow retrieval of suits, to install the docking hatch, to reposition the seats, etc.; if new designs would have helped, any suggestions on how to reduce the amount of loose equipment that must be found and installed, etc.

Design a plan to don suit rapidly.

It must be done sequentially (Note: unless cabin volume accommodates two crew donning simultaneously)

It might have been possible to do two at a time donning the suit, but it still would have been difficult.

A self-sealant is necessary.

(There was an additional, emergency garment during Gemini 7.)

Post-Summit Questionnaire Responses

Yes

Yes. Depends on leak rate, but why is he pressurized?
2. Docking hatch opening and stowage options

Make sure the hatch is created to comfortably accommodate a crewmember in a pressurized suit.

*Post-Summit Questionnaire Responses*

Yes

Yes

3. Stroking pallet (struts up vs. down); clearance options for moving about underneath and for potential maintenance / IFM scenarios

Do what is ideal for the mission. Obviously, space is needed. The Command Module is good.

*Post-Summit Questionnaire Responses*

Yes

Yes

4. Were there any issues/lessons learned with respect to reach or field of view to switches, controls, windows & displays during high-g and zero-g; did you participate in any ground-based centrifuge or zero-g flights and how did that prove useful in the design of these areas?

0 g was an asset when trying to reach for things. Take advantage of 0 gravity in designing.

The CM was confined, but still had reaching ability.

Get more astronaut participation at the design phase. Need to have operational consideration during the design and development stages.

*Post-Summit Questionnaire Responses*

Zero-G flights most useful. Better than pool for many operations.

Yes
5. In the case of a side on landing on a wave or ground landing of the same, would the Apollo seat and restraint system have been adequate; any suggestions on how to design it now?

Post-Summit Questionnaire Responses

Do not do ground landings unless you want to kill the crew(s). Seat design should allow for impacts on waves.

Keep the seat belts tight! Don't overly complicate it. Look at Russian designs.

Yes. I believe the system would have been okay. We did not stroke seats on landing with 2 chutes.

Apollo design was good for both!!

6. Recommendations on stowage of items in irregular spaces/in creative ways; how would you design it now?

Post-Summit Questionnaire Responses

Think about putting REID tags on each (or each important stowage item. This would allow quick electronic indication of each item’s location; even if misplaced after initial stowage.

Stow items as needed in volumes

Yes

Apollo was good!! Map

7. During EVA prep or post, were there any issues with umbilical plug-in locations, tangling with other umbilicals & people, umbilicals too short, long, correct number of each, etc.

No significant issues on LEM, but give plenty of space to don/doff.

Post-Summit Questionnaire Responses

Okay

8. Describe challenges of nominal and/or emergency suit donning in zero-G & suit stowage, given the small size of the spacecraft.
Post-Summit Questionnaire Responses

Practice, practice, practice, Apollo 16 crew did don and doff at least 6 times in LM simulator. It was tight but doable. 0g feels like bigger space than 1g. Tight quarters no big problems. See 7 above.

9. Describe any limitations or good points in the use of the windows to see the horizon during nominal and off-nominal ascent/entry as well as their use in viewing the LEM docking target during a rendezvous.

Post-Summit Questionnaire Responses

Windows should be designed to see what you need to see to land and/or rendezvous and no more.

Yes. Good visibility for docking. Used horizon as Entry attitude, Good!

Apollo was adequate.

Be very careful about PI who want to have windows without IR protection. It's an insidious trap with potentially serious consequences a filter.

10. Can you describe egress, human factors issues that have crew health and safety impacts?

Post-Summit Questionnaire Responses

The egress ingress of the LM was the most difficult because you had to arch your back over the ascent stage engine bell in the cockpit.

None, not anticipated.

Question is, what!!

11 Are there any suggestions to create privacy for mixed crews during the waste and fecal collection processes; how was privacy created during Apollo, did you go under the seat pallet, use fabric barriers, etc.

Post-Summit Questionnaire Responses

No privacy allowed. No room for it. Providing privacy in the CEV is dangerous to crew survival. The CEV should be 4.5 meters max diameter.

Just went to LEB -but tbr space, not privacy.

No. We were ready for this and did not seek privacy as I recall.
No privacy - but how do families live? Some privacy required - private space vs. practicality - don’t be bashful!!

12. With regard to having hot & cold water and a food warmer, how important is it to have these items vs. the precious space they occupy in the tight cabin confines; would this be considered a necessary comfort item in cases where there a lots of crew in a small space for several days, i.e., 6 crew to ISS?

*Post-Summit Questionnaire Responses*

Not a big deal. We had it in Apollo

We had hot & cold water. New meals w/warmer would be nice but not critical.

Hot & cold water is a must - food warmer is desirable.

**Radiation**

1. With regards to lunar surface operations, in the event of a solar event, can you describe any difficulties you may have had returning to a safe haven? What ideas can you offer on creating a safe haven in a remote area?

Put shielding that you can pull out on your rover, or maybe something you can hide under—perhaps dig a trench and sit in it.

*Post-Summit Questionnaire Responses*

Yes

2. Medical operations and regulatory requirements mandate that each crew wear a crew personal dosimeter (small device that measures radiation exposure level at the surface of the body) at all times throughout the mission. The crewmember’s evaluated exposure could be artificially high or low if the CPD is not worn. Can you suggest pre-flight or in-flight actions that would improve crew compliance with always wearing CPD?

*Post-Summit Questionnaire Responses*

Attach it to suit garments so the crew persons don’t have to locate it, find it and put it on. Make it invisible?

No. Training!
We always wore ours. Make it a mission requirement.

3. The crew can play a crucial role in managing their in-flight radiation exposures. This could be as simple as sleeping in well-shielded locations. Do you agree that the crew should actively manage their radiation exposure during a mission by monitoring their exposure and modifying their shielding? If radiation protective nutritional supplements or pharmaceutical agents were approved for spaceflight, would you consider using them?

Yes having the information about incoming radiation could help.

If protectants can work or reduce the health impact, then yes, we should have them available.

*Post-Summit Questionnaire Responses*

Yes

Yes

4. Current radiation detection technologies provide the ability for crew readout of real-time radiation levels, customizable alarms, and "hot and cold spot" mapping of the vehicle's habitable volume. Do you have preferences or advice on how these readouts or alarms should be designed? Would you have found this information useful during enhanced space weather events (SPEs)? Or during times when there is a loss of communications?

Should have active radiation detectors with alarms that sound when the dose gets too high for safety, so you can get back or find a safe place.

*Post-Summit Questionnaire Responses*

Yes

Yes

5. Active radiation monitoring either integrated into the suit or a rover would provide necessary dose information (i.e., rising radiation levels during a SPE) while EVA to provide for operational decisions that would work to ensure that the crewmember's dose is maintained within limits. Would you have a preference for where the monitoring device would be located?
They should be attached to each suit.

Post-Summit Questionnaire Responses
Yes. Each suit
Yes.

a. There is a plan for warning dosimeters as a means of early radiation detection and alert. How do you feel about this?

There is no problem with having these on the suits, however it may be too late once the alarm sounds.

How do you get a true forecast and warning system? It would be interesting to have more details.

Post-Summit Questionnaire Responses
Early warning is key.
Yes. Solar flare detection is a must.

b. Advance warning is currently very limited and there are issues with donning suits rapidly and plugging in umbilicals. How could this be made better?

The crewmembers did not remember problems with the connect/disconnect systems.

They had no problems in training or with the attachments and the disconnect systems may be even better now.

They were hot miked during prep and de-prep and those transcripts are available. Comments would have been made if there were problems.

It would have been difficult to get the suits on any faster than they did. If they tried too quickly, such as in the case of an emergency, they would have skipped some checks.

There were issues with waste management. Going back to the moon would be like "camping out", but Mars would be a problem.

Post-Summit Questionnaire Responses
No problem with normal donning -Don't have experience with panic mode.
Yes.
Exercise
Exercise

Exercise and Fitness

1. Did you feel physically fit prior to the mission, and did you have good strength and endurance while on the lunar surface?

   *Post-Summit Questionnaire Responses*

   Yes, we had exercise protocols in the ground and glove boxes to strengthen your hands.

   Yes and N/A

   Yes

   Yes, but I slept poorly -If I could do it all again, I would take a sleeping pill (I do not use them on Earth).

   Yes.

2. Did you feel more 'winded and fatigued' that you expected? Did you feel more unbalanced' or uncoordinated than expected while working on the surface?

   We got tired, but we were pumped up with adrenaline. Probably would wear off for long missions.

   *Post-Summit Questionnaire Responses*

   No Responses

3. What do you see as the role of pre-flight conditioning? What is your opinion of its importance to mission success for these short duration trips?

   - Make requirements known and plan time in the schedule to meet them.
   - Loosen the timeline.
   - Apollo crewmembers always scheduled time for running. Strength exercising was done at night on our own.

   *Post-Summit Questionnaire Responses*

   Good comments

   Yes.
4. Are there any aspects of your preflight or in-flight exercise training that you would change to better prepare you for your mission tasks?

Post-Summit Questionnaire Responses

No.

People are bright - give them imagination & they'll take care of themselves.

Size the flight suit slightly longer than the training suit. There must be accurate data by now.

No. Training adequate.

5. In terms of physical capabilities - what were the hardest and easiest tasks that you had to perform during lunar EVAs?

Repetitive hand gripping and forearm activities. Getting things out of the cases when they had been baked in was also tricky.

Post-Summit Questionnaire Responses

No Responses

6. Were there any physical tasks that you couldn’t do or had to modify substantially from the original mission description due to fatigue or injury or other factors?

There was some mental fatigue.

"There were short periods of time when mental attitude went into idle because there weren't any exceptional observations."

Post-Summit Questionnaire Responses

Not for me. (no mental fatigue)

Yes.

7. Was your task load and recovery time coupled well for your mission as a whole? Was it coupled well on a day-by-day basis (versus too easy or too hard)? If not, did inadequate rest between demanding tasks contribute to fatigue and/or injury?

Have two teams working EVAs on alternate days.

Give crewmembers time off with no responsibilities.

EVA day should not be all planned out.

Give objectives and allow crew to dictate their day to accomplish their tasks.
Post-Summit Questionnaire Responses

Yes.

a. During EVA day would it have been better to have a break during an EVA? Go out and come back in and go back out?

Do not break a day in half at all. Once out there, get it all done, no interruptions. If you have a suit that can allow you to be out longer, there might be a concern.

Once you get into a project you lose track of time. Contact with the ground is necessary and you have to have discipline.

8. Given your physical condition immediately post Landing, would you have been able to (1) egress unassisted from the Apollo capsule and (2) assist an injured crewmember with egress in an off-nominal, emergency scenario?

Yes, we could have gotten out, as well as assisted an injured crewmember.

Felt physically fit enough to do this unless there were high seas-could not do in those cases.

Post-Summit Questionnaire Responses

Yes

Yes.

9. How long did it take to return to normal daily activities following the mission?

- One crewmember felt normal almost immediately. Generally returned to normal activities within 48 hours.

- Another crewmember stated three days later he felt normal.

Post-Summit Questionnaire Responses

About 3 days to feel normal. About 2 weeks to fully recover conditioning.

Yes.
In-flight Exercise and Hardware

1. The Exer-Genie is mentioned in several of the debriefs. Did you use it? If so, in what configurations, for how long per session, and during what mission phase (e.g., surface, outbound, return phases)? Can you expand on its negative and positive impact? Do you think it was helpful in maintaining fitness or strength?

   - The consensus is you don’t need exercise on short trips (14 days or less).
   - Exercise is important preflight.
   - EVAs provide enough exercise.
   - Having it there is fine for those who want it, should not be a mandatory protocol to use it.
   - It is useful to have the knowledge that there are certain exercises to reduce fatigue.
   - Exercise feels good.

Post-Summit Questionnaire Responses

Yes. Didn’t work after a couple days. Retained heat.
Yes. Learn how to use the device

2. Exercise was reported to improve low back pain during the mission. Crews mentioned specific exercises but were unclear how they performed them. Can you describe the types of exercises you performed? Considering the design for the CEV/LSAM, can you explain how you might perform them in this environment? Did it help with back pain or stiffness related to confines of the vehicle?

   In addition to the Exer-bike during early Apollo, we did some running in place and isometrics. It can relieve less in your muscles.

   Exercise should be available without getting in the way of the other crewmembers.

Post-Summit Questionnaire Responses

Yes. Used outer couch rails to do pushups. Moving back as in sit-ups helps.
Yes

3. The crews mentioned that they did not want to perspire during exercise in the cabin, and backed off on the intensity to prevent perspiration from forming. What was your concern with perspiration?

   Hygiene was a concern because there were no showers and not a lot of towels. We didn't have these wet wipes to clean up with on the earlier missions.
On later missions the "wet" wipes had a bad odor.

*Post-Summit Questionnaire Responses*

Don't recall a problem. Filter good at removing odors.

Yes. No concern.

4. **Were there any stress relief/psychological benefits from using the Exer-Genie? Did its use impact other crewmember activities (due to small space in which exercise could be performed)?**

Yes the exercise can be a stress reliever or just put you in a better mood. Exercise can have a beneficial effect during the whole mission, just don't have specific schedules for it, let us do it as RnR.

*Post-Summit Questionnaire Responses*

No

Yes

5. **Do you think formal exercise is required on a two-week lunar mission to perform EVA tasks and to maintain fitness for egress on return?**

- Should not be a man mandatory protocol
- Should be physically and mentally ready
- "Would like to through by people who understand muscle."

*Post-Summit Questionnaire Responses*

Helps relieve minor aches, but not necessary on short flights.

No not required.

a. **The crewmembers have indicated that they do not want scheduled exercise periods on the timeline. They want to exercise on their own time. Is there anything else to add?**

No exercises were done for bone density during Apollo. This would be a problem on long-duration missions.

When the Exer-Genie was no longer used, crewmembers performed push-ups and ran in place.
6. Volume and upmass will be limited in exploration vehicles/habitat as it was on the Apollo vehicles. Given the limitations this will impose on possible exercise devices, are there any specific types of exercise (stretching vs. aerobic vs. resistance-type) that should be a priority for lunar sortie and lunar habitat missions?

Post-Summit Questionnaire Responses

Aerobic probably the best for long duration surface missions.
Watch out for devices that depend on friction - ours got so hot that it eventually destroyed the cord. It's dangerous.

No. Stretching best
Don't know
Any exercises that can be provided WRT space - h EVAs provide enough

7. Apollo 7: The crew suggested the Exer-genie could use some improvements. What type of improvements would you recommend and how can these improvements be incorporated into the devices planned for CEV/LSAM?

It needs to be reliable and simple to use.

Post-Summit Questionnaire Responses

No. Good device on Earth. Need something else in space. And know how to use it.

a. A more robust (and lightweight) piece of equipment is needed. Are there any comments to help in development?

Put as many capabilities in the vehicle as possible, because it will get used. Exercise throughout flight will be critical. A variety of exercises must be provided.

Post-Summit Questionnaire Responses

Yes.
8. Several crews stated that the exercise device got hot during sub-maximal use. The heat generated prevented stowage secondary to the crew’s concern of a fire hazard. What part or parts of the device generated this heat? How would you suggest designing the device differently to obtain maximal workloads and be safe, considering the mass/volume constraints of the CEV/LSAM?

Heat was generated in the rope.

A crewmember asked what will be done one week prior to returning, in order to counteract SAS during short flights. It was explained that high-intensity training will be used. The body should be worked hard so it counteracts orthostatic intolerance.

The blood volume needs to return to what it was originally.

The ASCRs work with the crewmembers individually and provide prescriptions for exercise. Although they do not monitor them daily, they do provide a program for them to use.

A discussion was held regarding how to get cardio for the entire pulmonary system with the differences between 1/6 g and 1 g?

G suits were discussed. The Russians use lower body pressure cuffs.

Exercise must be performed on the surface, as well. Decrement have not been completely eliminated in space flight so far.

Post-Summit Questionnaire Responses

See above -Friction of rope on control spindle -inherent to design. Don’t depend on friction on a small surface.

The rope on our Exer-Genie stretched. Friction clutch got hot

Yes
Food/Nutrition
Food/Nutrition

1. Initial allocation of space for food supplies on Apollo missions was 5003 cubic inches. Baseline food and packaging requirements were 4830 cubic inches. Over time, the food system volume values increased. By Apollo 14, the average volume/man/day was 188 cubic inches. This equates to a total of 7896 cubic inches required. Where was the extra food stored?

- The regular meals were stowed in one compartment in the left hand equipment bay.
- The problem was not stowage, but it was the garbage requiring twice the volume of the initial stowage.
- The radiated food was in foil and there were no hard containers.
- There was a lack of flavor or spice in the food. The bacon squares were the best food. It was something to stimulate the taste buds and for the flavor itself.

*Post-Summit Questionnaire Responses*

Yes

2. How did the additional 2893 cubic good get stored? Was all the food stowed together? Were only hard-sided containers used for food storage?

See #1 above.

*Post-Summit Questionnaire Responses*

don't remember

3. If you had to rank the overall importance of the contribution of each of the following to eating during flight how would you rank (very important, somewhat important or not important): 1. Lack of taste; 2. Lack of time; 3. Don't think it's critical if I lose a little weight; 4. Don't particularly like the food; 5. Food is somewhat difficult to prepare; 6. Sometimes nausea or gastrointestinal distress makes eating unappealing; 7. Lack of "social" interaction detracts from food intake.

*Post-Summit Questionnaire Responses*

The normal newer MREs are adequate. Rating the above is weird.

6 5 1 2 4 3 7

(1) Very important, (2) Very important, (3) Somewhat important, (4) Very important, (5) Very important, (6) Very important, (7) Not important.
(1) Somewhat important, (2) Not important. (3) Not important - drink water, (4) Not - you select your own, (5) Very, (6) Not, (7) Not.

4. There is some discussion not to have hot or cold water and/or a food warmer on the CEV.

Hot water is an absolute necessary on both vehicles.
Hot food is more comforting than cold food.
Find out how the original wet packs were put together.

*Post-Summit Questionnaire Responses*
Hot food is very important. Warmers may not be critical. Yes.

5. How important would you say heating your food was/will be during a short duration mission (less than 7 days) or a longer mission (more than 7 days)?

See #4 above.

*Post-Summit Questionnaire Responses*
Very important
Yes.

6. How important would you say cooling your food items was/will be during a short duration mission (less than 7 days) or a longer mission (more than 7 days)?

*Post-Summit Questionnaire Responses*
Unknown - Preservation for fresh items for long missions will need a refrigerator.
Not critical
Cool what? - ice cream - water - ice tea! Get real.

7. Were there any vehicle environmental changes during a mission that you recollect there being a change in food temperature that was either positive or negative?
**Post-Summit Questionnaire Responses**

No. No.
RG: No.

8. Was there any concern on the relative locations of the hygiene and waste areas and food stowage/galley area?

No we had to eat in the same place we pooped, but that is not the best situation, we just had to do it.

**Post-Summit Questionnaire Responses**

No.
Yes.

9. Was there any issue with EVA performance due to quantity or quality?

Lunch and plenty of water was needed on EVA

**Post-Summit Questionnaire Responses**

No.
Yes

10. It has been reported that bread packages often burst when the vehicle was depressurized, There was also report of an incident with chocolate pudding.

**Post-Summit Questionnaire Responses**

Fix the packages. No real problem.

a. Did you observe other products (especially wetpacks) that also lost packaging integrity during this time or at any other time during a mission?

No regular packages had any problems.
Post-Summit Questionnaire Responses

No.

The LM water gun leaked because a thread from one of our beta cloth garments or stowage bags got lodged in the valve opening. It was a very slow dribble. After getting fixed, it did not impede our delivery of H2O. I feel we got dehydrated because we lost our hot water source when we shut down the CSM. As a result we did not subsequently consume any of the powdered, freeze dry food and hence a loss of a lot of water one gets that way. We lived off the "wet packs" and cookie & bread cubes from the snack area. Secondly, with the low work load floating around in Zero g and the cold environment we just didn't get as thirsty as we normally would. I know that Jim is quoted as saying that we deliberately rationed our water. I can state that I did not ration, but obviously did not consume as much water as I should have.

b. Were you instructed to discard these items?

Post-Summit Questionnaire Responses

No

No

11. Apollo 10: How would suggest developing meal plan/food choices for time-critical activities to allow you to get necessary calories and fluid in a convenient manner?

Post-Summit Questionnaire Responses

What we do now in the Shuttle is adequate.

A-12, 13, 14, 15, 16, 17. What’s with 10?

12. Did it mean anything to be able to see the food through the packaging?

It helped to pick some things out, usually we could only tell by the labels.

Post-Summit Questionnaire Responses

No. Labels were okay.

No. You selected the menu.
13. Did you crave certain foods or types of foods?

Spicy and salty foods.

Post-Summit Questionnaire Responses

Coffee
Bean needed pasta.

a. Was the food bland? Would you have preferred spicier foods?

Not if it would cause a diarrhea problem.
Just more flavor in the foods.
A crewmember commented that they were told they would get individual menus, but that did not happen.

Post-Summit Questionnaire Responses

Yes, more taste

No.

14. How important was it for you to time out at least once a day and eat together?

We were on the same schedule for eating, sleeping, etc.

Post-Summit Questionnaire Responses

No. Very

Yes.

15. Did the lack of appetite or space sickness affect your performance during the mission?

Post-Summit Questionnaire Responses

No

No

You betcha! But/and it went away.

Yes on Skylab for 4 to 5 days.
16. What do you consider to be the major impediments to eating and maintaining weight during flight?

*Post-Summit Questionnaire Responses*

An overly ambitious timeline  
Time to do it  
For me SMS  
None. if you eat your plan.

Food taste and the time it takes to prepare and clean-up  
Eating ok, dehydration

It's my impression that the food in Apollo was uniformly OK preflight and absolutely unattractive in flight. I did not have that experience in Shuttle. Makes me think it is either O2 toxicity, reduced pressures, or, less likely, unaccelerated flight.

a. The crewmembers lost weight routinely...some lost 8-10 pounds. What can we do to make the food more palatable?

We were debriefed extensively. All of this information is available.

*Post-Summit Questionnaire Responses*

Weight loss was mostly due to sweating, & air cooling after landing in suits in the ocean. If liquid cooling was available, the loss would have been 2 lbs at the most.

TV dinners would be good.

Yes. Weight loss!

b. How important do you feel that it is to get sufficient calories in a day? Please provide an example (if any) of the importance of nutrition and food intake.

You need enough food to maintain your strength and alertness. One crewmember didn't lose any weight.

*Post-Summit Questionnaire Responses*

Yes. Need the energy

Yes. Adequate calories provided.
c. Do you feel that it is important to have a preflight eating plan that optimizes nutrition for the best possible nutritional status before flight?

*Post-Summit Questionnaire Responses*

Sure
No.
Just have the food taste like what it says it is.
Yes
Maybe
Yes

d. What is your attitude about supplements in general? If you were shown data that a supplement such as omega 3 fatty acids would be protective against certain health issues would that convince you to take the supplement?

Supplements could be good if stowage is a problem, no issue with using them.

*Post-Summit Questionnaire Responses*

No
Yes
Yes

e. Would data on the timing of exercise to food intake affect your behavior if shown that one type of eating pattern helped to maintain muscle mass more than another eating pattern?

*Post-Summit Questionnaire Responses*

Probably not
No
Maybe
Yes
Yes,
maybe
Yes
f. How important do you think optimal diet and food intake is to your overall performance?

*Post-Summit Questionnaire Responses*

Not very on short duration missions.
For long missions, it is important.
Adequate is good - nothing more here.
Very
Very important
Very

g. How important do you believe that rehab post flight might be if optimal diet and exercise were combined?

*Post-Summit Questionnaire Responses*

Not needed for lunar surface ops if crews do EVAs as much as practical.
Very
Very

h. Considering current packaging configurations, do you believe there to be any advantage/disadvantage relate to preparation and consumption as compared to Apollo-type packaging?

*Wet-packs.*

*Post-Summit Questionnaire Responses*

Packaging much better now.
Skylab cans were better - bags are tough - not appetizing.
Don't really know
Yes

i. Though rehydratables and wetpacks (currently known as thermostabilized and irradiated) required more resources than bite-size (cubes) items, do you believe there were specific bite-size items that were of high enough quality to compete for selection/provisioning?
Wet packs were best. They were good and they were easy to use. Rehydratable foods were fine. We liked most of the foods. Basically, it was trail food. It is probably much better today than it was then.

Post-Summit Questionnaire Responses

No, maybe snacks
Yes

Pharmaceuticals

In response to a question from a crewmember about how to qualify a pharmaceutical for space flight, Dr. Jones explained that most medications are tested on crewmembers prior to flight, however this does not account for possible altered characteristics in a new environment.
Dr. Fischer stated that there is no evidence that drugs have had different effects in space than on Earth. It may be necessary to alter the dose and/or the route of delivery, but it has the same effect.
Dr. Pool stated that we do not have a well-established understanding about this issue and we need to obtain the information somehow. We must target the specific information that we want, obtain the norms, and get an idea of what to do.
A number of experiments will take place, including bisphosphonates. This drug is really not intended for this population, but rather for osteoporotic women, so it is unknown how it will effect this population. We will be looking at calcium excretion and other bone markers, etc.
We will need to be able to archive urine and blood. We will also be looking at hydroxyfolie.
Crew Work/Rest Schedules
Crew Work/Rest Schedules

Sleep and Fatigue

1. The Apollo 15-17 lunar crews felt they were able to sleep and function adequately in the LM during the lunar surface ops for their 31+ hours on the moon, although they didn't sleep more than 3-4 hours at a time. What changes would the crew make in the LM to preserve sleep/daily activities for missions of 7-14-30 days? Should there be a hard fixed sleep period of 8-10 hours? What would be a nominal workday length?

- Give crewmembers a scheduled sleep period (eight hours of rest where nothing is scheduled).
- Staggered sleep distracts others from sleeping when one crewmember is moving around.
- Cannot dictate sound sleep, but must give crewmembers private time.
- A crewmember commented that "Circadian rhythm has nothing to do with space."
- Changing back and forth (sleep shifting) is not desirable

Consider mental fatigue and physical fatigue separately. Although there was not a great deal of physical fatigue, the mind was being used quite a bit. You can sometimes wear your brain out before your body is fatigued.

It took about 3 days to get adjusted to weightlessness and be able to sleep. The head is not stabilized on the pillow in 1/6 g. So you feel like you're falling off, but you get adjusted to the feeling.

There are terrestrial examples of circadian rhythm shifts in new environments (i.e., long-duration cave habitation). There are shifts when you leave the Earth's surface.

In space, the Schumann Resonance Frequency (SRF) must be considered. Discussions should be held with experts who have studied this.

The impact of the workload of mission control support personnel is also a factor. They need defined sleep periods and time off to keep the mission functioning.

It might be worth looking at the work cycles of Mission Control operations during Mir.

The crewmembers commented that the Apollo 13 crew was still able to function, even though they were the most sleep deprived of all missions.

The flight surgeons should be advocates for the crews.

The 8-hour sleep period should not be compromised even if the crew doesn't use all of it because they are just dozing part of the time.
2. The crews slept in their suits during surface ops for Apollo 11 through 14 and reported that suit discomfort led to a poor quality of sleep. Apollo 15 and subs slept outside of the suits, yet still reported less-than-optimum sleep. Can this be attributed to scheduling, environmental noise, lighting, tasks, ground communication, sleep shifting or difficulty in relaxing in a strange environment, or did other factors contribute?

Post-Summit Questionnaire Responses

I slept great. If folks are worried about the machinery failing, they won't sleep well. Even with pills, Charlie didn't sleep too good.

Fear of not being alert if an emergency came up -This can't work for long duration stays.

3. Sleep deprivation and fatigue caused by a host of factors was mentioned in medical debriefs. These factors included excessive cabin noise, comm. interruptions, sleep shifts, cold temperatures, and staggered schedules. How was crew performance and morale adversely affected by sleep deprivation and fatigue? Were critical operational activities impaired (e.g., TLI and TEI burns, lunar orbit, re-entry preparation)? What suggestions do you have to avoid such problems on future lunar missions?

• Apollo 13, were most affected by sleep deprivation, but were able to perform.

• We stuck to the plan. Didn't feel anyone wasn't performing to their level. It was not an issue.

• More attention was paid to the schedules than to crewmembers' sleep time.

• At one point, the decision was made to stop work completely and go to sleep on Apollo 13. There was a physiological and mental need to stop and sleep so we told the ground stop we have to go to sleep. It turned out to be the best decision in order to continue. Mental fatigue is a bigger factor than physical.

Post-Summit Questionnaire Responses

Apollo 15 crew slept at same time -and on Houston time. Made normal work day and sleep much easier. No diurnal shift.
4. Nearly all Apollo crews reported being tired on launch date, and medical debriefs indicate an intense pre-launch training schedule that caused fatigue. Can you suggest a reasonable training schedule 6-8 weeks before the launch date that will allow crews to launch adequately rested?

- The last week of training was mentally fatiguing because continually training for things that would not occur. The training schedule should allow for crews to concentrate on things that will be used for the nominal mission.

- Contradictory comment: "Don't remember saying they were tired at launch."

The crew planning timeline is critically important. Private communications have revealed a sense of frustration in crews trying to fit everything in. There must be a suitable plan in order to avoid serious operational problems caused by fatigue.

Dr. Pool stated that we should not take what was done during Apollo and use it as a model for Mars.

The crewmembers pointed out, however, that the lessons learned during earlier Apollo missions were helpful in later missions. The problems were still present during Skylab, however the timeline again improved in later missions.

The crew schedule should have slack early in the mission to allow time for learning/training.

The crewmembers reported that they were fatigued on launch day, due to the timeline for pre-launch training. They felt that much of the mental fatigue was due to the amount of non-essential training that was not operationally relevant.

One crewmember stated, however, that it was often the crewmembers who were asking for briefings if they needed additional information.

The timeline was sometimes less structured by the trainers than by the crewmembers themselves. The launch environment must be improved.

The pre-launch quarantine was helpful since there was time that wasn't scheduled. It allowed time for physical and mental recovery.

Post-Summit Questionnaire Responses

Just taper off the final week.

Yes. Schedule off time as part of prelaunch activities.

Yes. No wimps allowed.
Psychological Support
Psychological Support

1. An Apollo 12 debrief mentions a wish for recreational materials, such as books or music, during travel to and from the moon as there were stretches of time with little to do. Looking back, what effects would having access to such items meant for you? Is access to such items needed for the future missions?

"Don't remember having any time on my hands."

It is very desirable to know what is going on in the world itself, news, sports, etc. Give me some way of getting this information in order to relax. "Send me the newspaper. Allow me to live there the way I live here. In the morning, I have a cup of coffee and read the newspaper."

Maybe having electronic books would be good.

Little things will frustrate you and hinder performance.

Post-Summit Questionnaire Responses

A plus
We carried a tape machine and played music. Made living more normal.
Yes

a. Regarding time alone after dropping others off on the lunar surface, what would make this more comfortable? Crewmembers reported that they liked the extra time, but wanted recreational activities when traveling to and from the Earth. In designing the CEV, what could be brought along to provide activities for the crew?

The CEV should be made as autonomous as possible.

It is important to engage the mind on these trips. One crewmember reported that they did their own navigation and this gave them something to do. There are opportunities to look out the window. One crew used the x-ray spectrometer to take a picture of something that turned out to be a black hole.

One crewmember stated that he wouldn't change a thing, since he had no problems passing the time. He enjoyed the time off and there are always housekeeping activities in the command module that need to be done.

Post-Summit Questionnaire Responses

Talk it over with crew. Some might like to play chess with opponents on Earth. I was very comfortable. Had a heavy workload and enjoyed the time.

Yes
2. During the debriefs the lunar missions CMPs offered candid insight into the isolation and boredom they faced after the CDRJ LMP left for the moon until their return. What steps would you offer to ameliorate these concerns for future lunar crews?

Post-Summit Questionnaire Responses

I never felt isolated or bored. Obviously an individual matter.

XX. in the A-XX CM was 100% busy the whole time. If you know the moon, there should be plenty of experiments to do while going around up there.

Teddy bears

I was okay. Good to get rid of those 2 guys for awhile.

Would not worry about this - Have them take music and books and books on tape or CDs.

I never felt isolated nor bored. Getting rid of XXXX & XX for 42 hours was great - but still glad to see them come back! ! You had to be there.

I thought that the solo time was really precious. In fact. routine operational chores and flight plan maintenance was a nuisance. To get around this, we had Hank Hartsfield (CSM Capcom) run the flight plan when we had AOS so I could look out the window and contemplate what there was to observe. I'd resume flight plan responsibility on the back side. Thanks to some superb geology training, you could see an awful lot and test various hypotheses. And I didn’t have to listen to country and western music!
Crew Scheduling and Task Loading
Crew Scheduling and Task Loading

1. In designing future mission scenarios, what are your recommendations for optimizing operational success and crew health for each of the mission durations (including task loading, task timelines with recovery, conditioning to prepare for tasks and off-nominal events, etc.)?

*Post-Summit Questionnaire Responses*

Practice, practice on the surface in suits where the tasks are defined and duplicated just like on the moon.

Allow time for all activities such as eating, resting, exercise, experiments, etc. We were preoccupied with the science.

Subject is far reaching and requires a great deal of discussion - Different positions have different responsibilities, i.e., CDR, CMP, LMP, Payload Spec, Mission Spec, EVA, etc. all different stressors.

2. Were there any additional stressors, unique to Apollo and lunar surface vs. LEO? Are there any other Apollo/Moon unique factors to consider with regard to psychological preparation, support and scheduling?

A person should be left to figure it out themselves. You prepare yourself. You were probably mentally ready when you were selected. Once you volunteer, those decisions are gone and you are ready to go.

After Apollo 1 or 13 we all could have left but no one did. As far as any programs, if you need a program you have the wrong people.

Getting everything done in the time you had to get it done was the highest stressor. Time is the greatest asset and enemy. You never have enough of it.

You get to the point where you have to perform and the biggest fear was screwing up and making the wrong decisions. "Thou shalt not screw up, first commandment."

*Post-Summit Questionnaire Responses*

Yes

a. What are the merits and demerits of the two weeks in quarantine postflight?
There is disagreement about postflight quarantine. Some believe there is no possibility of anything surviving in a lunar surface environment that could be brought back and be dangerous to human beings. Others believe the postflight quarantine was justified because there may be unknowns. There was a question about why 21 days was the chosen period. Microbiologists advised that 21 days was about the maximum incubation period for any epidemics the world had seen. At the time, they didn't know about AIDS and other long-duration microorganisms that don't show up for a long time.

There was agreement that the quarantine allowed for postflight briefings and other activities to take place in a more tranquil environment without outside distractions.

Preflight quarantine is very valuable. From an operational point of view, it removed a large number of distractions from the last three weeks of preparations and the crews were much more rested.

Post-Summit Questionnaire Responses

Reduce the party load, although not critical.

Yes. Leprosy -21 days arbitrary (edited response)

| Schedule crews for two Lunar EVA days on and one day for maintenance, alternating crews throughout the week. | LAT and LAT defining architecture; to be placed in Ops Con document. |
| The hatch and ingress corridor should be sized appropriately for an inflated $1/6 g$ pressure suit. | Requirement for minimal hatch size in HSIR. |
| An airlock may make ingress/egress easier and will also be a good idea from a dust control standpoint. | Requirement for Airlock in EARD and CARD. |
| Surface activities can begin once operationally feasible. | Ops Con includes surface tasks for crew during landing day. |
| There is no special training needed for $1/6 g$ EVA's other than a familiarization session. | Lunar Crew Training Plan. |
| Limit navigation into craters to $< 20 - 26^\circ$ slope. | Ops Con; will need a Flight Rule. |
| Rover activities: CDR, LMP at risk for injury if not restrained. | Consider for Rover requirements document; Medical contingency Ops Con. |
| Risk for injury; Falling from a height; ladder, rim of a crater. | Need Flight Rule; Medical contingency. |
| Ladder rung height and width on the Lunar Module (LM) were good but the glove did not allow adequate grip for safety. | Revised handhold requirements in HSIR. |
| Ensure adequate water and food are available before and during lunar EVA. | Requirement in HSIR. |
| Lunar EVA should be performed as one continuous event. | Ops Con. |
| Plan the operations on the surface so that you protect the crews from themselves. | Will need Ground and Flight Rules to limit. |
| With extended ops on the moon, establish all the experiments in the first week. | Will need Ground Rules and put Expedition planning guidelines. |
| The Rover should have the ability to recharge the suit. | Consider for Rover requirements document. |
| Crews requested that an automatic position determination device be available to aid navigation on the lunar surface. | Consider for EVA system requirements document. |
| A robot should perform routine, systematic, repetitive, menial tasks (may help prevent repetitive use injuries). | Consider for EVA system requirements document. |
| Allow adequate time to practice mission activities in a variety of environments including analogs that allow preparation for off-nominal events. | Planetary exploration Analog WS to be held in March. |
| Allow adequate time in the schedule for all activities. | Need GRnC entry for this. |

Apollo Medical Operations Project recommendations

LAUNCH, LANDING, AND RECOVERY OPS

Provide adequate cooling capabilities for the crew on landing to mitigate the hot cabin contribution to crewmember seasickness.

96 Ground landings discouraged

97 Apollo seat configuration for water landings were adequate: the restraint system needs to include loose equipment items. Medication for motion sickness and fatigue will be available prior to re-entry.

99 Hatch should open outward and seal with pressure

100 Sea state should be limited to < 6-8 foot swells if recovery is to be delayed. Have food and plain water within reach of buckled crewmembers for delayed recovery.

101 Apollo Command Module hatch location and size was adequate for egress.

102 All control panels and switches should be within reach of crewmembers during launch and landing.

104 Training for pad abort was adequate and should be continued. Crew surgeon should be on the recovery vessel and not the helicopter.

FLIGHT SURGEON-CREW INTERACTION

Crew encouraged FS to "act as more of an advocate of the crew" than treat them as an experiment.

106 The collaboration established between the current flight surgeons and Apollo crewmembers should continue and be an example to future generations.

APPENDIX E
CORRESPONDENCE
May 9, 2006

Dear

The Space Medicine Division at NASA/Johnson Space Center is currently developing the medical requirements for the Crew Exploration Vehicle (CEV), Lunar Surface Ascent Module (LSAM), Lunar Habitat, and Advanced EVA suits.

In order for Medical Operations to write requirements for the new systems and hardware, a thorough review of the Apollo mission documents was conducted. This review identified areas that need further clarification before beginning development of future crew health and safety systems.

We request your attendance at a face-to-face meeting on June 7-9, 2006 in Houston. Our main goal is to elucidate any insight you may have into opportunities for improvement and to provide your ideas for future missions emphasizing the steps necessary to ensure crew health and safety based on your experience. The results of your efforts will be evident in the creation or modification of requirements for the exploration vehicles, suits, and mission activities, as well as flight surgeon support of exploration crews.

The first two days of this meeting will be private and limited to current flight surgeons, Apollo crewmembers, and administrative support personnel. The third day will be open to other parties interested in participating in the discussions. Please feel free to suggest additional invitees (e.g. members of the research community, current astronauts, Apollo flight surgeons, flight directors or engineering staff) that you feel would contribute to the third day.

Please confirm your desire to attend this meeting by May 26, 2006. Point of contact for the event and travel funding information is Dr. Rick Scheuring, (281) 743-1510, richard.a.scheuring@nasa.gov.

Sincerely,

James M. Duncan, MD
Chief, Space Medicine
NASA/Johnson Space Center
Dear Mr.

I certainly hope you accept our invitation to this June meeting as it will be very exciting to hear from you as to how we can create the best program for crew health and safety.

To best facilitate the meeting and maximize your time with us, we will have pertinent issues from the Apollo documentation researched and ready for discussion. For example, a couple of issues from the Apollo16 documents include:

1) **Crew comment** – Urine volume measurements were difficult at best and quite time consuming for the crew to perform. The procedures for the urine dump system were not well thought out.
   **Our questions** – A portion of body fluid is lost through insensible means (respiration, perspiration, etc.) not easily measured. Obtaining daily fluid input/output is an important indicator of hydration status, but not perfect.
   What system of maintaining accurate records of input/output would the crew recommend, given all the trouble they had with the water and waste management systems?

2) **Crew comments** – During the three lunar EVA’s, the crew often worked harder during “rest” periods (as evidenced by heart rate data) than during work periods. However, the crew did not feel this level of physical activity pushed them to their exercise capacity limits.
   **Our questions** – The three lunar EVA’s totaled 20 hours and 17 minutes. Although you did not feel physically challenged during your lunar EVA’s, can you offer any insights how you might have felt carrying out this surface activity timeline over the course of 7-14 days? How do you feel the pre-flight EVA training program prepared you for lunar EVA? What would you do differently in your training for these longer surface sorties?

These are a few examples of the many questions that only the Apollo crew members can answer which is why this meeting is very important to future missions. We’ve discussed this project with LG Stafford, Dr. Schmitt, and Capt. Cernan, who are in agreement with our primary objectives: to make sure those issues encountered during the Apollo missions are brought forth and discussed to optimize crew health and performance and prevent “reinventing the wheel.”

During your visit, we are including a tour of several mock-ups of the exploration vehicles including the CEV and lunar habitat. Also, if you prefer, we can coordinate your visit with the
Longitudinal Study group and the Flight Medicine Clinic to complete your annual physical exam during the same trip.

Please call me at 281-461-2774, e-mail at Richard.a.scheuring@nasa.gov with your intentions or if you have any questions. Thank you for considering this invitation and we look forward to working with you.

Sincerely,

Richard A. Scheuring, D.O., M.S.
Apollo Summit-Project Manager
Advanced Projects/Flight Surgeon

Richard,

Nothing is based on my input since I don't recall ever making one on the CEV. I was supporting Northrop Grumman on their proposal effort and felt it might be a conflict of interest. You also sent me one for inputs on the Landing craft crew accommodations, relative lunar surface stay. I did not respond on that one either as I did not land and have the experience to relate.

Now that the competition is over and the CEV overweight, I will look at your email and provide my thoughts.

 Regards,
 Fred Haise
From: tkmattingly
Subject: Comments on your Apollo Medical Briefing charts

Rick,

Thanks for sharing your results. A couple of thoughts from reading the presentation follow.

1. Lots of good ideas but we have to remember that spaceflight will always be constrained by mass, volume and power. Suggest that while you have everyone’s attention you might try to prioritize these desires. Recommend use of the pair-wise comparison technique to help eliminate unrecognized internal pressure. If you’re not familiar with the technique, it involves making a list of all options and then having each evaluator compare the importance of each possible pair. This requires establishing a single objective, such as, “if I was returning to the moon and could have only one improvement, which of each pair would I prefer having?” Then, start with number one on the list and test it against each other suggestion, one at a time. Then you rank order the ideas according to the number of these pair-wise votes. That is #1 vs. #2, #1 vs #3, etc. then #2 vs. #3 ...... You and your evaluators may be surprised at the results. Armed with this info, you can make better choices when the cost and schedule crunch time arrives.

2. I think I mention that the taste of food in Apollo was lousy but some of the same foods tasted good in shuttle. I attributed this to the lack of a diluent gas but may be due to some other aspect of the cabin environment such as total pressure.

3. The only discomfort (nuisance) I encountered in space flight was the periodic episodes of nasal congestion. During Apollo, it would come and go. During shuttle, I noticed that 30 seconds on the treadmill would clear the sinuses for hours. I tried it on others and they had the same reaction. I believe this is due to the redistribution of fluid within the body during micro-g. Seems consistent with the observed swelling of our faces. Also wonder if this might be applicable to headaches. Can’t tell from experience because I was one of those fortunate enough to have avoided such episodes.

4. Lots of comment on impotence of Exer-genie. I didn’t find it particularly satisfying or useful but found the Shuttle treadmill to be a magic device. I think the body as a whole responds far more to the large mass muscles in the legs than to the arms.

5. You observed that while many of the lunar crews experienced trauma to parts of the hands during lunar surface EVA, this had not been an issue in training. It occurs to me that we all had our custom flight suits made as small as possible to maximize mobility. What we didn’t account for was the fact that our bodies stretch when gravity is removed. Some folks had a hard time zipping up on orbit. We made some measurements during early STS flights that showed how much our height extended on rbit. Don’t think we ever thought about measuring changes in arm length but it would seem logical. If we had tight suits and our bodies extended, even in 1/6th g, this could account for your observation.
6. I think I mentioned that the biggest contributor to glove forces was the thermal insulation layers. If you’re thinking of augmenting the gloves with mechanical aids, you might consider using a pressure sensitive sensor on the interior of the glove and sending this signal back to a mechanical aid on the back of the hand. It should be sized to offset only the glove (finger) bending loads, not create a bionic hand. It should work in both directions and have the ability to be disabled without adding additional loads.

Good show. The time is right to start think about these things again.

TK
From: Harrison Schmitt  
To: Scheuring, Richard A. (JSC-SD)  
Subject: Sleep in apollo

See CAPS embedded below. Just remember that operations will start out conservative and then get more realistic as experience is gained.

Harrison

-----Original Message-----

Harrison H. Schmitt

Dr. Schmitt-

The Apollo recommendations are getting a lot of attention on the Constellation side of things these days. That being said, a question has come up regarding sleep (below), the procedure for a cabin depress on return from the moon, and the land vs. water landing issue. The sleep issue is primarily concerned with sleep on the lunar surface. I remember the lunar crews stating that lack of sleep was multifactorial, but environmental issues, such as inability to adequately block sunlight from the windows, loud background noise, and a cold floor were some of the more pressing issues. The hammock seemed to work okay from what I remember for the short stays, but how well would they work for longer duration missions?

FROM MY PERSPECTIVE, APOLLO 17 BENEFITED FROM ALL THE EXPERIENCE AND MISTAKES OF PREVIOUS MISSIONS, AT LEAST I WENT TO A LOT OF EFFORT TO MAKE THIS THE CASE. SUNLIGHT (WE PUT SHADES ON THE WINDOWS), NOISE (IT WAS COMFORTING TO HEAR THINGS DOING WHAT THEY SHOULD DO AND IF THEY HAD NOT, IT WOULD HAVE BEEN "A WAKE-UP CALL"), HAMMOCKS (VERY COMFORTABLE IN ONE-SIXTH G) WERE NOT PROBLEMS AND CERTAINLY WOULD BE OKAY FOR A WEEK. I AM NOT SURE CERNAN SLEPT AS WELL AS I DID (I WOKE BRIEFLY EVERY TWO HOURS OR SO, I THINK), BUT YOU SHOULD ASK HIM IF NOT COVERED IN HIS BOOK. I THINK WE ALL SLEPT WELL IN THE CM - RON CERTAINLY DID! THEY COULD NOT WAKE HIM ONE MORNING WHEN HE WAS ON WATCH.

I CAN ONLY SPEAK FOR MYSELF, BUT I DID NOT FEEL SLEEP DEPRIVED BEFORE ANY LUNAR EVA. I LITERALLY FELT AS READY AFTER EACH SLEEP PERIOD AS I DID BEFORE THE FIRST EVA.

Currently, we are working out a 144 hour depress scenario where the cabin has vented to space over time and the leak cannot be found. Consequently the crews are in their suits for the ride home. Did you have any such procedures during Apollo? Lots of issues
associated with this scenario and I would like some guidance on how you might have handled it.

I DON'T REMEMBER HOW APOLLO RULES STARTED OUT BUT APOLLO 17 AND MOST OTHER MISSIONS IF NOT ALL WERE OUT OF THE SUITS FOR THE RETURN, BUT DID HAVE PROCEDURES FOR EMERGENCIES. WE DID NOT WEAR THEM EVEN FOR ENTRY. I WOULD NOT LET THE ENGINEERS ASSUME THAT THE CREW WILL STAY IN THE SUITS FOR 144 HOURS! THE ORION MUST BE BETTER THAN THAT.

The recommendation from the summit was that the Apollo crews preferred a water landing over land. This is a hot topic because Constellation is opting for land at this point in time.

THIS IS A DESIGN ISSUE AND A DESIGN CONFIDENCE ISSUE. I WOULD PLAN A MISSION FOR WATER LANDING TO BUILD CONFIDENCE, MAYBE THAT "APOLLO 8" STYLE MISSION YOU ARE CONSIDERING.

The Apollo concern was off-nominal re-entry putting the spacecraft in downtown LA or some other populated area. Water landings allowed a much greater margin of error. However, the vehicle cannot be re-used and this seems to be one of the drivers for a land landing. Were there other concerns that made water preferable? Also, the outward opening hatch in the CM has raised a number of questions, but I think this recommendation came from the Apollo 204 experience.

YES. WHAT ARE THE QUESTIONS?

The draft of the completed paper is almost ready to send out. I am briefing the Constellation control board (CxCB) on Wednesday and fully expect to field questions related to these and other issues. Your time is greatly appreciated. Please call me (281.743.1510) if you would rather discuss this on the phone than email.

Thanks again,
Rick

Sleep in apollo  

Dear Dr. Scheuring,

I found your e-mail awaiting my return from a little time in Washington.

With regard to sleep issues, my Apollo procedures documents are in storage so I must depend on memory, which is not very good.

We did not have any sleeping facilities in the LM, which was marginally acceptable for the 3 day period. For anything longer than that, reasonable sleeping accommodations should be provided to assure that productive time could be assured during the working day. The problems we had: (1) light in the cockpit (2) pump noise (3) cold temperatures, and (4) inadequate sleeping facilities -- all seem to readily solvable.

I cannot comment on the hammock. We had only a improvised leg sling in the A-11 LM. The Command Module sleeping sacks seemed to work reasonably well.

We kept our pressure suits available for whenever they might be needed. I'm sure we had some kinds of procedures, but I can't remember any details without the check lists. Operating in pressurized suits is difficult and brings with it a substantial amount of risk: inadvertent switch or control operations, inability to reach controls, substantial difficulty in moving about the cabin, etc. For that reason, Gemini and Apollo crews pressed for a 'shirt-sleeve environment'. The pressure suit is mandatory for situations such as the one you postulate, but when not absolutely required it is genuinely disadvantageous.

The Mercury, Gemini, and Apollo launch trajectories were all over water. So the ability to safely land in water was required for any launch abort. The Soviet launch trajectories were principally over land. So the ability to land safely on the land was required for their launch aborts. Once providing the ability for the launch case, it made sense (with our extreme weight limitations) to use the same system for both.

I suspect Orion/Ares will also need to provide a launch abort ability for water landings. Whether there will be a substantial weight penalty for adding land landing ability, I do not know. I certainly understand the reluctance to accept the costs of water landings as a routine matter, so I could support a land landing if I were convinced that there was a very high probability of landing close to the intended destination.

These are just some random thoughts, so I provide them with some reluctance, but I am confident that you will consider them in the light of their incompleteness.

Sincerely,

Neil Armstrong

Subject: Sleep in Apollo

Dear Mr. Scheuring:

In regards to your e-mail of April 9th -- in zero gravity sleep is not a problem. The body can be lightly restrained within a body bag. Body heat will form a blanket within the bag. If the noise level is low and once the person gets used to sleeping in a strange environment, there should be no problem.

In a gravity environment such as the lunar surface, consideration has to be given to adequate space, cold surfaces, body pressure points and the noise level. From what I heard, these factors were marginal in the lunar module.

Water landings were preferred in Apollo for the following reasons:

1. The availability of large bodies of water to accommodate long landing foot pads dictated by high reentry velocity.
2. The consistency of the landing surface and the absence of uneven terrain and large obstacles.
3. The elimination of wings and therefore weight.
4. The ease to position the recovery force.
5. The necessity to plan to land in water in emergency since Apollo launched east from Cape Canaveral.

I hope this can be of help.

Medical requirements for the future Crew Exploration Vehicle (CEV), Lunar Surface Access Module (LSAM), advanced Extravehicular Activity (EVA) suits and Lunar habitat are currently being developed. Crews returning to the lunar surface will construct the lunar habitat and conduct scientific research. Inherent in aggressive surface activities is the potential risk of injury to crewmembers. Physiological responses to and the operational environment of short forays during the Apollo lunar missions were studied and documented. Little is known about the operational environment in which crews will live and work and the hardware that will be used for long-duration lunar surface operations. Additional information is needed regarding productivity and the events that affect crew function such as a compressed timeline. The Space Medicine Division at the NASA Johnson Space Center (JSC) requested a study in December 2005 to identify Apollo mission issues relevant to medical operations that had impact to crew health and/or performance. The operationally oriented goals of this project were to develop or modify medical requirements for new exploration vehicles and habitats, create a centralized database for future access, and share relevant Apollo information with the multiple entities at NASA and abroad participating in the exploration effort.
