1 OVERVIEW

1.1 INTERNATIONAL SPACE STATION PAYLOAD ACCOMMODATIONS

External payload accommodations are provided at attach sites on the U.S provided ELC, U.S. Truss, the Japanese Experiment Module Exposed Facility (JEM–EF) and the Columbus–EPF (External Payload Facilities).

The Integrated Truss Segment (ITS) provides the backbone structure for the ISS. It attaches the solar and thermal control arrays to the rest of the complex, and houses cable distribution trays Extravehicular Activity (EVA) support equipment such as handholds and lighting; and providing for Extravehicular Robotic (EVR) accommodations using the Mobile Servicing System (MSS).

It also provides logistics and maintenance, and payload attachment sites. The attachment sites accommodate logistics and maintenance and payloads carriers, zenith and nadir. The JEM-EF, a back porch-like attachment to the JEM Pressurized Module, accommodates up to eight payloads, which can be serviced by the crew via the JEM PM’s airlock and dedicated robotic arm. The Columbus-EPF is another porch-like platform that can accommodate two zenith and two nadir looking payloads.
1.2 DATA CONTROL AND HANDLING ARCHITECTURE

The ISS C&DH system consists of hardware and software that provide services for command, control, and data distribution for all ISS systems, subsystems, and payloads. The top level (system level) C&DH architecture contains redundant Command and Control (C&C) Multiplexer Demultiplexers (MDM), and MIL–STD–1553B control buses. The payload service includes the payload MDM for Low Rate Data Link (LRDL) (1553B local bus) data and command distribution, and a High Rate Data Link (HRDL) for payload-to-payload communication and data downlink service. LRDL (other than payload safety-related) data is downlinked via the HRDL to the ground. Safety-related data is routed via the C&C MDM to the S-band data services for downlink. The Personal Computer System (PCS) is used by the onboard crew for command and display interface. Payload commands can be uplinked from a ground site, issued from the PCS, or issued by a payload MDM automated procedure. The C&DH architecture diagram is shown in Figures 1.2–1 and 1.2–2.

Figure 1.2-1: C&DH Architecture

Type of Data Transferred:
1 commands to payloads
2 health and status, C & W
3 broadcast auxiliary data
4 payload files
5 telemetry data
EXPRESS LOGISTICS CARRIER (ELC)

The ELC is designed to carry a variety of Orbital Replacement Units (ORUs or spares), first time outfitting cargo, and external payloads (science experiments). The ELC, fully integrated with mounted cargo/payloads, will be delivered to the ISS and may be returned to Earth in the Shuttle cargo bay. Transfer of the fully integrated ELC between the Shuttle cargo bay and the ISS is accomplished using a series of robotic maneuvers utilizing both the the Shuttle Remote Manipulator System (SRMS) and the Space Station Remote Manipulator System (SSRMS). Transfer of the fully integrated ELC may include an intermediate staging on the ISS Mobile Servicing System (MSS) on the Mobile Remote Servicer Base System Common Attach System (MCAS) or Payload ORU Accommodation (POA). The US EXPRESS logistics carriers will be located both Port and Starboard on the space station as indicated in the following figures. The views from the different ELC locations can be earth viewing or deep space viewing. Each view will also contain some percentage of Space Station structure or adjacent cargo or payload structure.

Figure 2.1-1: ISS and ELC's

![ISS and ELC's](image)

Figure 2.1-2: S3 ELC's

![S3 ELC's](image)
2.1 POWER

ISS provides two 3kW feeds at each S3/P3 attach site. Each site must use one of the feeds as Main (primary) power, for operational use, and the other as Auxiliary (keep–alive). Attached Payloads may use both power feeds simultaneously provided the power bus isolation requirements are met. Specific constraints on the use of Main power and Auxiliary power by Attached Payloads are defined in the payload–unique ICD. Attached Payloads delivered to the ISS by the Shuttle should nominally expect to be unpowered during transfer to the ISS for up to 4.5 hours. Payloads that cannot withstand a lack of power for this duration must prearrange with the ISS for special accommodations, or provide their own power source. During the assembly of ISS, electrical power generation hardware and software will be installed to provide power to

\[\text{SSP57003, 3.2.2.2.2, pg 3-31.}\]
operate the ISS hardware as well as user payloads. Prior to Assembly Complete, payloads should be capable of withstanding several periods of approximately eight hours of power disruptions. Planned power outages will be documented in SSP 50112, Operations Summary Document. However, unplanned payload power outages may also occur.

2.2 COMMUNICATION\(^3\)

Each P3 and S3 attach site has access to both the Low Rate Data Link (LRDL) and the High Rate Data Link (HRDL). The LRDL is a MIL-STD-1553 bus and is used for data and command distribution. The HRDL is an optical fiber system that provides payload–to–payload communication and data downlink service. LRDL (other than payload safety–related) data is downlinked via the HRDL to the ground. The Personal Computer System (PCS) is used by the onboard crew for command and display interface. Payload commands can be uplinked from a ground site, issued from the PCS, or issued by a payload Multiplexer/Demultiplexer (MDM) automated procedure. The capabilities of the HRDL and LRDL are summarized in Table 2.3.1.

---

\(^3\) SSP57003, 3.3.2, pg 3-43, SSP57021 Section 4.
The mechanical vibrations generated from all of the ISS's systems are transmitted throughout the structure. The vibrations can affect experiments sensitive to acceleration. Both attached and pressurized payloads are required to restrict their mechanical vibrations so as not to disturb these sensitive experiments while the ISS is in Microgravity Mode. Microgravity Mode is an operation mode that precludes certain activities to minimize the vibration environment at some of the pressurized payload racks. Figure 2.4-1 and 2.4-2 show the predicted microgravity environment at the S3 and P3 respectively. These figures depict the predicted environment while the ISS is not in Microgravity Mode. Microgravity Mode is predicted to be lower.

**NOTE:** Based on five (5) Payloads per LRDL

1. 348 kbps from the Payload MDM to the C&C MDM, 192 kbps to the S-band for downlink
2. low rate data is sent via the HRDL to the ground
3. P/L MDM can support 10 commands per second (allows buffering of commands)
4. C&C MDM can support 8 commands per second (ground command through-put limit)
5. Aggregate payload are all payloads on USOS C&DH System (internal and external P/Ls)

### 2.3 MICROGRAVITY

The mechanical vibrations generated from all of the ISS's systems are transmitted throughout the structure. The vibrations can affect experiments sensitive to acceleration. Both attached and pressurized payloads are required to restrict their mechanical vibrations so as not to disturb these sensitive experiments while the ISS is in Microgravity Mode. Microgravity Mode is an operation mode that precludes certain activities to minimize the vibration environment at some of the pressurized payload racks. Figure 2.4-1 and 2.4-2 show the predicted microgravity environment at the S3 and P3 respectively. These figures depict the predicted environment while the ISS is not in Microgravity Mode. Microgravity Mode is predicted to be lower.

---

Figure 2.5-7:  S3 Upper Truss, -X, Orbital Sunrise (left), and Orbital Noon (right)

Figure 2.5-8:  S3 Upper Truss, -Z, Orbital Sunrise (left), and Orbital Noon (right)
2.5 POINTING ACCURACY

Limitations exist for the degree of pointing accuracy on any payload attachment site. The S3 site has a fixed alignment error of $0.2^\circ$-$0.5^\circ$ /axis, $3\sigma$. There is also a time-varying error (with a period of the order of an orbit) of $\pm 0.08^\circ$ for roll and pitch, and $+0.23^\circ$/-$0.10^\circ$ in yaw due to thermal bending of the truss. There is also a random error of $0.001$-$0.02^\circ$/axis, $3\sigma$ in position knowledge.

2.6 EXTERNAL CAMERAS

There are several remote cameras located along the truss.

---

10 See http://mod.jsc.nasa.gov/do14/ISScamp.html
Figure 2.8-1: External Camera Port Locations and Views

There are at least 14 external camera locations with cameras to operate between them. If a particular camera view is required but not available, a camera may be moved to a location that supports it.\footnote{ISS Familiarization Guide, TD9702A, July, 1998.}
3  JAPANESE EXPERIMENT MODULE EXPOSED FACILITY

The Japanese Experiment Module Exposed Facility (JEM–EF) is an external platform for conducting scientific observations; earth observations; and experiments in an environment exposed to space. The JEM-EF/payload interface on the JEM-EF side is the Exposed Facility Unit (EFU). There are a total of 12 EFUs on the JEM-EF, 9 of which are available for users. The other three are used for the JEM-ELM-ES and for temporary storage. Figure 3-1 shows the JEM-EF flight unit under construction at the JAXA facility in Tsukuba, Japan, and Figure 3-2 is a block diagram of the EFU locations. The JEM-EF provides payloads electrical power, data, and active thermal control.

Figure 3-1: JEM-EF under construction at JAXA Facility in Tsukuba, Japan

Figure 3-2: Location of JEM-EF EFUs
3.1 POWER
Each EFU provides 3 kW of main power and 100 W of survival power on two separate buses.

3.2 COMMUNICATION
The JEM-EF provides eight high data rate channels, eight video data channels, and seven Ethernet channels.

3.3 MICROGRAVITY
The mechanical vibrations generated from all of the ISS’s systems are transmitted throughout the structure. The vibrations can affect experiments sensitive to acceleration. Both attached\(^\text{12}\) and pressurized payloads are required to restrict their mechanical vibrations so as not to disturb these sensitive experiments while the ISS is in Microgravity Mode. Microgravity Mode is an operation mode that precludes certain activities to minimize the vibration environment at some of the pressurized payload racks.\(^\text{13}\) Figure 3.4-1 shows the predicted microgravity environment at the JEM-EF. These figures depict the predicted environment while the ISS is not in Microgravity Mode. Microgravity Mode is predicted to be lower.

---

\(^\text{12}\) See SSP 57003,
\(^\text{13}\) See SSP 41000, SSP 50036 for more information.
3.4 JEM-EF VIEWS
Attached Payloads may require a view of the sky or of the Earth. The following Figures below depict modeled views from the JEM-EF. The user may wish to request a particular site depending on the exact viewing requirement.

Figure 3.5-1: JEM-EF and Coordinate System

Figure 3.5-4: JEM Exposed Facility, -X, Orbital Sunrise (left), and Orbital Noon (right)

Figure 3.5-5: JEM Exposed Facility, -Z, Orbital Sunrise (left), and Orbital Noon (right)
15 JEM AIRLOCK

The JEM is unique among the USOS in that it has a payload airlock. The airlock provides the capability to pass JEM-EF payloads between the pressurized cabin and space. The JEM Airlock can accommodate a payload up to a volume of 6.4 m x 8.3 m x 1.605 m in volume and up to 300 kg in mass. It is nominally operated once a week with a maximum usage of two operations per day. The JEM-EF arm moves the payload between the JEM airlock and its place on the JEM-EF and a slide table is available to move experiments or Orbital Replacement Units (ORUs) between the PM and EF. Additional information on the JEM airlock can be found at http://iss.sfo.jaxa.jp/iss/kibo/develop_status_07_e.html
4 COLUMBUS EXTERNAL PAYLOAD FACILITY (EPF)\textsuperscript{16}

The Columbus-EPF provides four attach sites: 1 nadir-facing, 1 zenith-facing, and two starboard-facing. Each attach site is compatible with the EXPRESS Pallet adapter, or other, custom-built adapter. Figure 4-1 illustrates the location of the EPF and some example payloads.

![Columbus Module with External Payload Facility](image)

Figure 4-1: Columbus Module with External Payload Facility\textsuperscript{17}

The interface is a removable adapter that attaches to the Columbus-EPF sites. Each payload may have a mass of up to 290 kg, including the adapter.

\textsuperscript{16} Many of the details come from ISS European Users Guide, UIC-ESA-UM-0001, ESA, Issue 1, Rev.0.
\textsuperscript{17} From ISS European Users Guide, UIC-ESA-UM-0001, ESA, Issue 1, Rev.0, Figure 3-1.
4.1 POWER
Each attach site is provided up to 1.25 kW by two 120 VDC redundant power feeds. All four locations are provided a maximum of 2.5 kW.

4.2 COMMUNICATIONS
Each attach site is provided a 1553-B low rate data line for status data such as Caution and Warning, failure detection, etc. Each attach site is provided an Ethernet medium rate data line, for transfer of commanding, ancillary data, and file transfer with rates up to 1.55 Mbps. The high data rate line interfaces to the Video Data Processing unit, and transmits up to 32.426 Mbps in increments of 32 kbps.

4.3 MICROGRAVITY
The mechanical vibrations generated from all of the ISS’s systems are transmitted throughout the structure. The vibrations can affect experiments sensitive to acceleration. Both attached and pressurized payloads are required to restrict their mechanical vibrations so as not to disturb these sensitive experiments while the ISS is in Microgravity Mode. Microgravity Mode is an operation mode that precludes certain activities to minimize the vibration environment at some of the pressurized payload racks. Figure 4.4-1 shows the predicted microgravity environment at the Columbus-EPF. These figures depict the predicted environment while the ISS is not in Microgravity Mode. Microgravity Mode is predicted to be lower.

Figure 4.4-1: Microgravity Environment in COF-External Platform Facility (EPF)

Figure 4.5-5: Columbus-EPF, Looking –Z, Orbital Sunrise (left), and Orbital Noon (right)
5 ATTACHED PAYLOAD TRANSPORTATION
Attached payloads may be transported to the ISS by the Space Shuttle, Japanese HTV or other ISS transportation vehicles. Attached payloads in the Space Shuttle are transported in the cargo bay, and attached payloads in the HTV are transported in its Unpressurized Carrier. Small attached payloads may be transported by any vehicle to the ISS’s pressurized section, and then deployed by the JEM-EF robotic arm via the JEM airlock, or by EVA via one of the ISS’s airlocks.

5.1 US SPACE SHUTTLE
Attached payloads are delivered by the Space Shuttle in its cargo bay. EXPRESS Pallets and the AMS will be transported as single units in the cargo bay. Separate external payloads will be carried up on a ‘cross-bay’ carrier (Integrated Cargo Carrier (ICC), Lightweight Multi-Purpose Equipment Support Structure (MPESS) Carrier (LMC), Unpressurized Logistics Carrier (ULC)), or ‘sidewall’ carrier.

6 COMMAND AND CONTROL OF ATTACHED PAYLOADS
Payload operations are controlled by the flight crew, mission and payload controller, and automated processes. The C&DH system supports both manual and automated control for all nominal and planned contingency conditions. Payload commands may be issued from on-board automated command blocks, the Portable Computer System (PCS), or uplinked from the ground. Procedures are automated (pre-programmed) where practical to relieve the crew workload and to preclude a need for crew activities to maintain or initiate payload functioning during normal communication outages.

The payload developer may receive data from an attached payload and issue payload commands while it is in operation on-orbit. For payload developers who require near real time data from their attached payload, the onboard C&DH and the Communications and Tracking (C&T) system downlinks payload data to the Payload Operations Integration Center (POIC) first with ancillary data then forwarded to a payload developer’s facility. In addition, the C&DH extracts previously specified ancillary data necessary for payload developer processing of payload data from the core operations data stream. The C&DH system forwards these data through the C&T system for near real time downlink to the payload developer’s facility. The mode of data transmission is dependent upon the nature of the payload and the payload developer’s data requirements. Payload developers may receive data in near real time, at prescheduled times and as playback anytime up to one year after the receipt of the payload or ancillary data.
7 EXTRAVEHICULAR ACTIVITY (EVA)
For ISS, there are two types of EVAs: nominal and contingency. For Attached Payloads, only contingency EVA is available.

8 MEAN MAINTENANCE CREW HOURS PER YEAR
The Attached Payloads will be allowed a maximum allocation of Mean Maintenance Crew Hours Per Year of eight hours for contingency EVA only.

9 NATURAL ENVIRONMENT
The natural environment surrounding the ISS is of importance to the payload community for at least two reasons:
(1) It may affect the design and operation of Attached Payloads; and
(2) it may be the object of investigation for experiments conducted using the payload equipment. The objective of this description is to define the natural environment as it might affect the design and operation of payload equipment. The inclusive environments described here include:
A. Neutral Atmosphere
B. Plasma
C. Charged Particle Radiation
D. Electromagnetic Radiation (EMR)
E. Meteoroids
F. Space Debris
G. Magnetic Field
H. Thermal, Pressure, and other Physical Constants
I. Gravitational Field
Note that the space debris and electromagnetic environments include elements produced by the activities of human beings: orbital debris and radio frequency radiation generated on the earth. These latter two environments are included in this discussion because they are part of the ambient environment to which the ISS and its payloads are exposed. Detailed descriptions of direct interactions of orbiting elements with the earth's atmosphere are contained in SSP 30425, Space Station Program Natural Environment Definition for Design.
9.1 PLASMA ENVIRONMENT
A plasma is a quasi-neutral gas of charged and neutral particles that exhibits collective behavior. The particles' movements are controlled to a great extent by the Earth's magnetic field and the solar wind, but their collective behavior and movement generate electric and magnetic fields that, in turn, affect the particle's motion and the motion of other charged particles far away. Plasmas are usually described by their density, the chemical composition of the ions, and the electron and ion temperatures.

9.2 SPACECRAFT - PLASMA INTERACTIONS
A spacecraft in LEO accumulates electric charge from the plasma in order to establish electrical equilibrium with the plasma, a process called spacecraft charging. Spacecraft surfaces tend to accumulate a negative charge. Charging of passive surfaces is usually not a problem, however, for active surfaces, e.g., solar arrays and structure tied electrically to them, arcing and related significant effects can occur, depending upon the grounding scheme and the magnitude of the spacecraft imposed voltages.

9.3 CHARGED PARTICLE RADIATION
Penetrating charged particles are produced from two sources: magnetospheric particles and cosmic rays. Magnetosphere particles are accelerated from the plasma by processes inside the magnetosphere and occur only within terrestrial space. Cosmic rays exist in interplanetary space and enter terrestrial space. The motion of both kinds of particles is controlled by the earth’s geomagnetic field. Charged particles present a significant challenge to design and operation of most attached payloads. A high level of radiation will significantly affect materials, chemical processes, and living organisms. It will also affect electronics by causing soft upsets (referred to as Single Event Upsets (SEUs)), degrading performance and sometimes producing permanent damage. In addition, ionizing radiation will affect the propagation of light though optical materials by altering their optical properties.

---

Excerpt from Space Station Program Natural Environment Definition for Design, SSP30425 Rev B.
Cosmic rays produced from galactic sources typically make up less of the total dose of radiation, in rads, than trapped protons. However, these cosmic rays produce significant effects. They are responsible for SEUs, latch–up in microcircuits and, along with trapped radiation–belt protons, the nuclei induced radio–activity in most materials. Cosmic rays also induce noise by production of ionization in devices such as charged–coupled devices and by production of Cherenkov and fluorescence radiation in photomultiplier tubes.

For specific design issues, the actual anticipated radiation environment must be calculated. SSP 30512, Space Station Ionizing Radiation Design Environment, and SSP 30425 provide significantly more detail and information concerning available tools for calculating the expected environment. SSP 30425 describes the general shape of the Van Allen belts following the shape of the geomagnetic field. This means that the Space ISS penetrates most deeply into the belts in the region of the South Atlantic Anomaly. Because the flux is increasing with altitude in the region of 300 to 1000 kilometers, the most intense radiation encountered in the anomaly, as shown in Figure 10.3-1 as the brightly colored area over South America extending out into the southern Atlantic Ocean.

![Figure 10.3-1: Representative data of Radiation Dosage in Low Earth Orbit Similar to ISS](image)

### 9.4 ELECTROMAGNETIC RADIATION

Electromagnetic noise sources of significance at the ISS extend from direct current to x–ray. Only natural and remote man–made Electromagnetic Radiation (EMR) sources are considered here. The categories of noise producers are as follows:

- Galactic
- Solar
- Near–Earth natural plasma
- Man–made radio noise

---

The highest power densities expected to be irradiating the ISS are from the solar radiation in the ultraviolet and visible portions of the electromagnetic spectrum. The ultraviolet radiation can damage materials exposed to it. SSP 30425, paragraph 7.2, describes the degree of exposure of the payloads to the solar ultraviolet radiation environment. Other effects of EMR to be considered include radio noise and the effects of field strengths from the natural sources at the ISS. Field strengths produced from quasi–static field structures in the plasma have typical values around 25mV/m, but can be larger. These values generally occur at latitudes greater than 50°.

9.5 **METEOROIDS/ORBITAL DEBRIS**
The orbital environment contains a large number of naturally occurring and man–made objects that might impact the ISS and payloads attached to it. Objects range in size from a mass of less than 0.62 cm to objects with a mass of much more than a meter across. Most of the orbital debris is located at altitudes less than 2,000 km. SSP 30425, section 8.0, specifies the Meteoroids/Orbital Debris (M/OD) environments to which the ITS S3 M/OD critical items are exposed.

9.6 **MAGNETIC FIELD**
The earth’s magnetic field, besides acting directly with the ISS to produce electric field gradients in the Station and its components, traps charged particles and deflects low–energy cosmic rays. It is also basically a dipole field. The magnetic field at altitudes up to approximately 2000 km is determined by this near–earth field, but above this altitude strong currents of charged particles within the magnetosphere cause deviations. The earth’s magnetic field is not constant and fluctuates with time (may be cyclic). There are various analytical models in existence (computer programs) to calculate trapped radiation and the field strength expected to be encountered by the ISS for a specific time. The natural on–orbit electromagnetic field environment to which payloads will be exposed is defined in SSP 30425, section 7.0. The natural magnetic field created by the earth to which payloads are exposed in low earth orbit is defined in SSP 30425, section 9.0.

9.7 **THERMAL, PRESSURE, AND PHYSICAL CONSTANTS**
Detailed evaluations of external environments require the use of many thermal, ambient pressure, and other physical constants. To assist in the consistent use of physical constants for detailed analyses, SSP 30425 provides listings of constants that can be used in developing models of the environment.

9.8 **GRAVITATIONAL FIELD**
A model of the gravitational field which takes into account the earth’s non–uniform mass distributions is provided in SSP 30425, section 11.0.

9.9 **CONTAMINATION**
The induced environment associated with the ISS will be strongly influenced by activities associated with its operation. For example, the level of induced environment will be increased during Space Shuttle docking and periodic reboost. It is prudent, therefore to define two conditions of the induced environment: quiescent periods and nonquiescent periods. Quiescent periods provide an induced environment consistent with designed measurement capability. For nonquiescent periods, it is assumed that the disturbed environment will be unacceptable for some measurements; however, the environment shall not produce conditions that preclude returning to unrestricted measurements as soon as the disturbing activity is terminated. Disturbing activities leading to nonquiescent periods shall be of short duration, resulting in most of the operational time being quiescent. Nonquiescent periods shall be scheduled and users shall be notified in sufficient time to take appropriate action.

---

24 Edited from Space Station External Contamination Control Requirements Document, SSP 30426, Rev D.
All materials used in hardware which will be exposed to space vacuum must have low outgassing characteristics as defined by a total mass loss of $\leq 1.0$ percent and a volatile condensable material of $\leq 0.1$ percent. Lower outgassing rates may be required for hardware which has large view factors to other hardware and for local regions such as window cavities.

The contribution to the molecular column density created by the presence of ISS contamination sources along any unobstructed line of sight is required to not exceed $1 \times 10^{-4}$ molecular-cm$^{-2}$ for individual released species. This includes contributions from outgassing, venting, leakage and other ISS contamination sources but does not include ram-wake effects. Molecular column density requirements may be exceeded for line of sight through volumes in space of high molecular density near gas vents. Specifically, the molecular column density limit may be exceeded for all lines of sight parallel to and within one meter from the vent axis. The vent axis will be oriented to preclude direct plume impingement on the JEM's exposed facility and attached payload truss locations.

As the ISS moves through the Earth’s rarefied environment, a ram-wake effect is created (i.e. density build-up preceding forward-facing surfaces and a density decrease on aft facing surfaces). Buildup on surfaces which have some exposure to ram can be as high as 60 times the ambient density. Attached Payloads that are sensitive to such a density should be carefully located relative to large surfaces to preclude interferences. A change in the composition of the surface local environment can be expected due to either reaction with the surface or recombination occurring on or near these surfaces.

The release of particulates from the ISS is limited to one particle 100 microns or larger per orbit per $1 \times 10^{-5}$ steradian field of view as seen by a 1 meter diameter aperture telescope. This includes contributions of particulates originating from external ISS surfaces, compartments vented to space, movable joints, vents (of solids, liquids and gases) and other ISS particulate sources but excludes particulates in the natural environment and their effect on ISS hardware (i.e. their impact on ISS surfaces).

There are several areas on the ISS’s external surface (solar arrays, thermal radiators, observation windows, truss attached payloads, and the JEM-EF) where the contamination fluxes are assessed. The flux of molecules emanating from the ISS are limited such that 300K, the mass deposition rate on the sampling surfaces are limited to $1 \times 10^{-14}$ g-cm$^{-2}$ sec$^{-1}$ (daily average), and will not exceed $1 \times 10^{-6}$ g cm$^{-2}$ yr$^{-1}$.
