DRIVERS
UNITY POWER FACTOR CONVERTER

ORIGIN OF INVENTION

The invention described herein was made in the performance of work under a NASA contract and is subject to the provisions of Section 308 of the National Aeronautics and Space Act of 1958, Public Law 85-568 (72 Stat. 435; 42 USC 2457).

BACKGROUND OF THE INVENTION

This invention relates to apparatus for achieving unity power factor for electrical loads, and more particularly to an ac-to-dc or dc-to-ac converter with unity power factor at the AC port. Electric utility companies are vitally concerned about characteristics of user load currents because phase displacement of the waveforms of current with respect to supplied voltage waveforms create undesirable power-transmission losses resulting in a low power factor.

The term power factor, used to characterize transmission efficiency and to indicate how well the supplied power is utilized, is defined as the ratio of actual power to the product of effective voltage and current. For maximum efficiency of transmission of AC power, the voltage and current must be in phase at both the source and the load end of the transmission line.

The maximum power factor is unity. Practical values, however, are often much lower due to reactive loads. Utility companies at times discourage large users of power from creating low power factors by assessing a rate penalty which is based upon measured power factor. In other cases, the utility company may add inverse reactance at the load to compensate for load reactance, but that approach for increasing the power factor makes use of resonant circuits tuned to the fundamental line frequency, which requires reactive components that are extremely large and heavy. Furthermore, changes of load reactance lead to decreased power factor because compensation reactance is fixed.

Some applications require conversion of AC source power to DC load power. Battery chargers and ac-to-dc converters for control of variable speed DC motors or for DC power distribution, are examples. Supplementary AC utility power is sometimes generated from DC sources, such as solar arrays, fuel cells, etc. The dc-to-ac or ac-to-dc converters degrade power transmission if unity power factor is not obtained. Conventional converters use rectifiers or switches with firing-angle delay to control voltage conversion. Such methods result in low power factor and have the added disadvantage of requiring low-frequency filtering components, which are large and heavy.

Power transmission losses can be minimized if the power factor of the converter itself can be adjusted to unity, instead of providing compensation to the utility power line to accommodate converters with poor power factors. Some efforts to develop converters with unity power factor for such large loads as railway electric locomotives are being made. One converter operates with AC current pulses occurring at the fundamental frequency of the utility line. These pulses are symmetric with respect to peak AC voltage, but the pulsating current generates high electromagnetic interference (EMI). In a second converter, developed for a constant-voltage application, inductance in series with the AC line smooths high-frequency voltage pulses in the converter to provide low EMI and low harmonic content while maintaining high power factor. This second converter is described in a paper presented at the 1977 IEEE International Semiconductor Power Conversion Conference by Hans Kielgas and Reiner Nil1 titled "Converter Propulsion Systems with 3-Phase Induction Motors For Electric Traction Vehicles". In a third converter, inductance is used in the DC line as well as in the AC line to filter internal high-frequency pulses. Very little is known about this third converter, and it has not been field tested. All of these converters operate only with a fixed DC bus, and this imposes severe limitations on potential applications.

The approach of the second converter referred to above appears to have the greatest promise. A low-power transistorized ac-to-dc converter was assembled to examine the feasibility of extending applications to include adjustable DC voltage. It was found that an important restriction on this approach originates not from the controller but from the power stage configuration. DC voltage must be greater than peak AC voltage to control peak AC current. Otherwise, current can rise to the short-circuit value, limited only by the reactance of the inductor. Limiting short-circuit current with inductance is not practical in many cases because of the large inductor required. The significance of this consideration is to preclude use of the circuit in the important class of applications that require control of the AC current at low DC voltages, e.g. full range control of DC motors. A converter which removes these and other constraints, and makes possible simplified load power factor correction to unity can have significant impact on electrical power conservation, is the subject of this application.

SUMMARY OF THE INVENTION

In accordance with the present invention, a converter is provided which so controls ac-to-dc or dc-to-ac conversion that the voltage across an inductor coupling AC ports to a storage capacitor through full wave rectifying diodes will cause the current through the inductor into the capacitor to follow a reference current, i_{ref}, where the reference current is proportional to and in phase with the voltage, e, across the AC ports. The current, i, into the inverter is thus controlled to be in phase with the voltage, e, across the AC ports, a condition required for unity power factor. The control is achieved by selectively operating switches to effect control of the inductor, L_{1}, to the positive or negative terminal (±V_{θ} or -V_{θ}) of the storage capacitor, or to zero volts, depending upon whether i is greater or less than i_{ref} and depending upon whether e is positive or negative. While i is positive, it is connected to zero volts if i < i_{ref} within the hysteresis tolerance of a comparator, and to the positive terminal of the capacitor if i > i_{ref} and while e is negative, it is connected to zero volts when i > i_{ref} and to the negative terminal of the capacitor if i > i_{ref}. In that manner it is forced to follow i_{ref} within the hysteresis tolerance of the comparator.

The novel features that are considered characteristic of this invention are set forth with particularity in the appended claims. The invention will best be understood from the following description when read in connection with the accompanying drawings.
BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a block diagram illustrating the manner in which a unity power factor (UPF) converter constructed according to the present invention is used.

FIG. 2 is a schematic diagram illustrating an exemplary embodiment of the present invention.

FIG. 3 illustrates schematically a switch which represents the action of electronic switches in the circuit of FIG. 2.

FIGS. 4a and 4b are graphs useful in understanding the present invention.

FIG. 5 is an exemplary logic diagram of a specific exemplary embodiment of the switch controller in FIG. 2.

DESCRIPTION OF PREFERRED EMBODIMENTS

The new dc-to-ac or ac-to-dc converter circuit to be described makes it possible to attain operation with unity power factor by the use of high frequency switching which is responsive to a control signal to regulate the waveform and phase displacement of the AC port current. The arrangement shapes the AC current waveform to a sinusoidal waveform and synchronizes it in phase and frequency with the AC voltage. Distortion is minimized by attenuating the fundamental and all harmonics of the switching frequency using small filters at the AC and DC ports. This is in contrast to the much larger filters required for use with resonant circuits operating at line frequency. The arrangement generates a low EMI.

The circuit and its operating theory are described below. The new arrangement is capable of effecting either inversion (dc-to-ac) or rectification (ac-to-dc), and also has the unique capability to provide bilateral power control in the manner indicated in FIG. 1, for power flow in either direction between a unity power factor (UPF) converter 10 and a UPF converter 11.

Potential applications are seen for interfacing AC and DC transmission lines; for integration with utility power grids receiving supplementary ac power from distributed DC power sources such as batteries, solar arrays, fuel cells, RTGs, and rotary electrical generators powered by wind, engine or heat; for load leveling using electrical power from various sources including those mentioned; for full range, smooth speed control of electric trains and vehicles, and for industrial process control. The arrangement also makes it possible to operate with a DC voltage which can be adjusted higher or lower than the peak AC voltage.

A simplified schematic of a unity power factor converter is shown in FIG. 2. The AC voltage and current at AC ports, and DC voltage at DC ports are respectively designated as e, i and E, I and e, i respectively in FIG. 3. In response to sensed signals in and E, i and e, the controller determines which of the transistor switches Q1 through Q4 are to be turned on or off to emulate the action of a switch S, indicated in FIG. 3, which is shifted from the nominal 0 position to either the +Vc or the −Vc position or from one of those positions to another, in order to make i proportional to e within a hysteresis band indicated in FIG. 4a for the special case of large positive, which is to connect the switch to 0 if i is less than in or to +Vc if i is greater than in. While e is negative, the switch is connected to 0 if i is greater than in. By itself, the circuit and its operating theory are described below. The new arrangement is capable of effecting either inversion (dc-to-ac) or rectification (ac-to-dc), and also has the unique capability to provide bilateral power control in the manner indicated in FIG. 1, for power flow in either direction between a unity power factor (UPF) converter 10 and a UPF converter 11.

shunt the diodes in the bridge, and the diode D2 as to cause the current i through the inductor L1 to follow the reference current, iref derived from the source voltage e, and synchronized in phase and frequency with the source voltage e. Once the current i is caused to be in phase with the voltage e, the condition required for unity power factor is achieved.

The scheme described with reference to FIGS. 4a and 4b for the controller 14 may be implemented in a number of ways that will readily occur to one skilled in the art. For example, a saturable operational amplifier (comparator) could be used to continually monitor the polarity of the signal e and produce a logic level 1 when positive and a logic level 0 when negative. The current signal i could then be compared with the current signal iref using a simple differential amplifier circuit which performs the function,

\[ E_o = A (E_2 - E_1) \]

where \( E_2 \) is proportional to iref and \( E_1 \) is proportional to i, followed by a saturable operational amplifier which again yields a logic level 1 when positive, i.e. when \( i < iref \), and a logic level 0 when negative, i.e., when \( i > iref \). The controller logic could then be implemented in accordance with the following table.

<table>
<thead>
<tr>
<th>e</th>
<th>iref</th>
<th>Va</th>
</tr>
</thead>
<tbody>
<tr>
<td>+</td>
<td>+ (true)</td>
<td>0</td>
</tr>
<tr>
<td>+</td>
<td>- (false)</td>
<td>+Ve</td>
</tr>
<tr>
<td>-</td>
<td>+ (true)</td>
<td>-Ve</td>
</tr>
<tr>
<td>-</td>
<td>- (false)</td>
<td>0</td>
</tr>
</tbody>
</table>

An alternative implementation for the switch controller 14, which is preferred because of the manner in which voltage signals proportional to the signals i and iref are derived in FIG. 2, will now be described with reference to FIG. 5. An advantage of this preferred implementation is that it is then not necessary to monitor the polarity of the voltage, e. Instead, two comparators 21 and 22 are employed to compare the current i with the reference current iref which is proportional to and in phase with the voltage e. The first comparator 21 has a narrow hysteresis, and it performs essentially the same function as the current comparator in the scheme discussed above. The second comparator 22 has a wider hysteresis for the purpose of determining by inference whether the sign of the voltage e is positive or negative. Assuming the following hysteresis levels:

- - - - i++
- - - - i+
- - - - i12
- - - - i+
- - - - i-1

where i+ and i- correspond to the hysteresis levels of the comparator 21 with narrow hysteresis relative to the reference signal, and i++ and i- correspond to a reference comparator 22 with wider hysteresis relative to the reference, crossing or exceeding these hysteresis levels with the signal i as it is compared with the reference iref will produce the conditions of the following table where i1 = i++, i-1 = i++, i- = i++.

<table>
<thead>
<tr>
<th>i1</th>
<th>i2</th>
<th>Vc</th>
<th>Q1</th>
<th>Q2</th>
<th>Q3</th>
<th>Q4</th>
<th>Q5</th>
</tr>
</thead>
<tbody>
<tr>
<td>i-</td>
<td>i-</td>
<td>+Ve</td>
<td>0</td>
<td>1</td>
<td>0</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>i+</td>
<td>i-</td>
<td>0</td>
<td>1</td>
<td>0</td>
<td>1</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>i+</td>
<td>i++</td>
<td>-Ve</td>
<td>1</td>
<td>0</td>
<td>0</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>i-</td>
<td>i++</td>
<td>0</td>
<td>1</td>
<td>0</td>
<td>1</td>
<td>1</td>
<td></td>
</tr>
</tbody>
</table>

When the sign of both comparators is negative, i.e., when i+ and i++ are both exceeded comparator switches Q2, Q3 and Q4 are closed to connect terminal +Ve of the storage capacitor to the inductor L1. When the sign of both comparators is positive, i.e., when i- and i-- are both exceeded, the transistor switches Q1, Q2 and Q5 are closed to connect terminal -Ve of the storage capacitor to the inductor L1. At all other times transistor switches Q1, Q3 and Q4 are closed to connect the inductor to the current return line, thus avoiding any contribution of positive or negative current from the storage capacitor. An exemplary logic network for implementing this table is shown in FIG. 5. For example, if the outputs of both comparators 21 and 22 are "positive" i.e., logic level 1 for i+ and i++ exceeded, gates G1 to G3 and inverters I1 to I4 cooperate with the art. For example, a saturable operational amplifier i,ef using a simple differential amplifier circuit which signal i could then be compared with the current signal in phase with the voltage e, the condition required for polarity of the signal e and produce a logic level 1 when performs the function, i<iref and a logic level 0 when negative, i.e., when i

An advantage of this preferred implementation is that it is then not necessary to monitor the polarity of the voltage, e. Instead, two comparators 21 and 22 are employed to compare the current i with the reference current iref which is proportional to and in phase with the voltage e. The first comparator 21 has a narrow hysteresis, and it performs essentially the same function as the current comparator in the scheme discussed above. The second comparator 22 has a wider hysteresis for the purpose of determining by inference whether the sign of the voltage e is positive or negative. Assuming the following hysteresis levels:

- - - - i++
- - - - i+
- - - - i12
- - - - i+
- - - - i-1

where i+ and i- correspond to the hysteresis levels of the comparator 21 with narrow hysteresis relative to the reference signal, and i++ and i- correspond to a reference comparator 22 with wider hysteresis relative to the reference, crossing or exceeding these hysteresis levels with the signal i as it is compared with the reference iref will produce the conditions of the following table where i1 = i++, i-1 = i++, i- = i++.
this arrangement over that of Reiner and Nill, supra. This arrangement will permit the voltage at the DC ports to go to zero under some feedback load control, and will provide for bidirectional power flow, i.e., provide for either AC to DC conversion (rectification) or DC to AC conversion (inversion) with unity power factor at the AC ports, i.e., with the current in phase with the voltage e at the AC ports. All that is required for the latter (inversion) is for the phase of the signal $i_{ref}$ that is proportional to e to be 180° out of phase with e 10 instead of in phase with e.

Although particular embodiments of the invention have been described and illustrated herein, it is recognized that modifications and variations may readily occur to those skilled in the art. It is therefore intended that the claims be interpreted to cover such modifications and variations.

What is claimed is:

1. A unity power factor conversion circuit, capable of effecting either dc-to-ac or ac-to-dc conversion, and capable of providing bilateral power control from a DC source, or load, at DC ports to an AC load, or source, at AC ports using a storage capacitor and a full wave rectifier to store energy in said capacitor from said AC ports, said circuit having a first inductor to couple said AC ports to said capacitor and a second inductor to couple said DC ports to said capacitor, means for selectively switching at high speed said first inductor to +V<sub>c</sub> at a positive terminal of said capacitor, −V<sub>c</sub> at a negative terminal of said capacitor, or to zero volts at a point on the current return path of said AC source, or load, and means responsive to a comparison of the current i through said first inductor with a reference current $i_{ref}$ proportional to and in a predetermined phase or antiphase relationship with the voltage e of said AC source, or load, for controlling said high speed switching means to connect said first inductor to the positive or negative terminal of said storage capacitor, or to zero volts, depending upon whether i is greater or less than $i_{ref}$, and depending upon whether the voltage e is positive or negative, such that when e is positive, said first inductor is connected to zero volts when i < $i_{ref}$ and to the negative terminal of said capacitor if i > $i_{ref}$ and when e is negative, said first inductor is connected to zero volts when i < $i_{ref}$ and to the negative terminal of said capacitor if i < $i_{ref}$, whereby the AC source, or load, current i is forced to follow the voltage e.

2. A unity power factor conversion circuit as defined in claim 1 wherein said reference current $i_{ref}$ is in phase with said voltage e for AC to DC conversion.

3. A unity power factor conversion circuit as defined in claim 1 wherein said reference current $i_{ref}$ is in antiphase with said voltage e for DC to AC conversion.

4. A unity power factor conversion circuit as defined in claim 2 with a second circuit identical to the first, except that the second includes means for inverting the phase of the reference current $i_{ref}$, and an AC transmission line connecting the two circuits at their AC ports to transmit power from a DC source connected to the second circuit to a DC load connected to the first circuit.

5. A unity power factor conversion having two AC terminals and two DC terminals comprising a storage capacitor, an inductor, a diode, full-wave rectification means having two input terminals and two output terminals, one input terminal connected to one of said two AC terminals by said inductor and the other input terminal connected to the other of said AC input terminals, one output terminal connected to one terminal of said capacitor, and the other output terminal connected to both one DC terminal and the other terminal of said capacitor through said diode polarized to conduct current to said capacitor, DC filter means for coupling said other terminal of said capacitor to the other one of said DC terminals, electronic switching means for selectively connecting either one terminal of said capacitor to said one input terminal of said rectifying means while the remaining terminal of said capacitor is connected to said other input terminal of said rectifying means, or said other terminal of said capacitor to said one input terminal of said rectifying means while the remaining terminal of said capacitor is connected to said other terminal of said rectifying means, or to connect one input terminal of said rectifying means to the other input terminal of said rectifying means, in response to control signals, means for deriving a reference signal proportional to the voltage across said AC terminals with a predetermined constant phase relationship, means for deriving a second signal proportional to current through said inductor, and control means for producing said control signals as a function of said reference signal and said second signal depending upon whether the second signal is greater or less than the reference signal, and depending upon whether the voltage across said AC terminals is of one polarity or the other, to force the second signal to follow the reference signal, whereby a predetermined phase relationship is maintained between current through said inductor and the voltage across said AC terminals, where said phase relationship is in phase for ac-to-dc inversion, and in antiphase for dc-to-ac conversion, with unity power factor conversion in either case.

6. A unity power factor converter as defined in claim 5 wherein said full-wave rectification means is comprised of a diode bridge comprised of four diodes, and said switching means is comprised of five transistors each connected in parallel with a different one of said four diode bridges, each of said transistors being operative to conduct current in a direction opposite current through the diode across which it is connected to shunt the diode when the transistor is turned on.

7. A unity power factor converter as defined in claim 5 wherein said control means is comprised of a first comparator with narrow hysteresis and a second comparator with wider hysteresis, each of said first and second comparators being connected to said reference signal and said second signal to produce an output signal proportional to the reference signal minus the second signal, and logic means responsive to the output of both comparators to connect the one terminal of said capacitor to said inductor connected to one AC terminal when the output of said comparators are both positive and to connect the other terminal of said capacitor to the other AC terminal, to connect the other terminal of said capacitor to said inductor connected to one AC terminal when the output of said comparators are both
negative and to connect the one terminal of said capacitor to the other AC terminal, and at all other times to connect the inductor connected to one AC terminal to the other AC terminals.

8. A unity power factor converter as defined in claim 7 wherein said fullwave rectification means is comprised of a diode bridge comprised of four diodes, and said switching means is comprised of five transistors each connected in parallel with a different one of said one coupling diode and said four bridge diodes, each of said transistors being operative to conduct current in a direction opposite current through the diode across which it is connected to shunt the diode when the transistor is turned on.

9. A unity power factor converter as defined in claim 8 wherein said phase relationship is in phase for ac-to-dc inversion.

10. A unity power factor converter as defined in claim 8 wherein said phase relationship is in antiphase for dc-to-ac conversion.
