**ABSTRACT**

A solid acid material is used as a proton conducting membrane in an electrochemical device. The solid acid material can be one of a plurality of different kinds of materials. A binder can be added, and that binder can be either a nonconducting or a conducting binder. Nonconducting binders can be, for example, a polymer or a glass. A conducting binder enables the device to be both proton conducting and electron conducting. The solid acid material has the general form MₑₓHₓ(XO)ₓ⁻.

This application claims benefit of U.S. Provisional Applications, Ser. No. 60/116,741, filed Jan. 22, 1999; Ser. No. 60/146,946, filed Aug. 2, 1999; Ser. No. 60/146,943, filed Aug. 2, 1999 and Ser. No. 60/151,811, filed Aug. 30, 1999.

STATEMENT AS TO FEDERALLY-SPONSORED RESEARCH

The invention described herein was made in the performance of work under a NASA contract, and is subject to the provisions of Public Law 96-517 (U.S.C. 202) in which the Contractor has elected to retain title.

FIELD

The present application describes a proton conducting membrane formed using an solid acid in its solid phase. More specifically, the present application teaches a proton conducting membrane, formed using an solid acid mixed with a supporting binder material, that is impermeable to fluids such as gas and water, can operate without hydration, and has high proton conductivity.

BACKGROUND

Proton conducting materials have a number of applications. Proton conducting membranes are widely utilized in devices which use a chemical reaction to produce or store electricity, or use electricity to drive a chemical process. Materials which conduct both protons and electrons (“mixed proton and electron conductors”) are utilized in related applications.

Electrochemical devices depend on the flow of protons, or the flow of both protons and electrons through a proton conducting membrane. Exemplary electrochemical devices include a fuel cell, an electrolysis cell, a hydrogen separation cell, a battery, a supercapacitor, and a membrane reactor. There are other electrochemical devices which also use a proton conducting membrane.

An important use for proton conducting membranes is in fuel cells. Fuel cells are attractive alternatives to combustion engines for the generation of electricity because of their higher efficiency and the lower levels of pollutants they produce. A fuel cell generates electricity from the electrochemical reaction of a fuel e.g. methane, methanol, gasoline, or hydrogen, with oxygen normally obtained from air.

There are three common types of fuel cells used at temperatures close to ambient. A direct hydrogen/air fuel cell system stores hydrogen and then delivers it to the fuel cell as needed.

In an indirect hydrogen/air fuel cell, hydrogen is generated on site from a hydrocarbon fuel, cleaned it of carbon monoxide (CO), and subsequently fed to the fuel cell.

A direct methanol fuel cell (“DMFC”), feeds methanol/water solution directly to the fuel cell, e.g., without any fuel processing. One type of DMFC has been described, for example, in U.S. Pat. No. 5,559,638. There are various advantages and disadvantages inherent within all three configurations. All are, to a greater or lesser extent, limited by the performance of the proton conducting membrane.

Nafion™, a perfluorinated sulfonic acid polymer, is often used as a membrane material for fuel cells which operate at temperatures close to ambient. Other hydrated polymers have also been used as proton conductive materials. Membranes of modified perfluorinated sulfonic acid polymers, polyhydrocarbon sulfonic acid polymers, and composites thereof are also known. These and related polymers are used in hydrated form. Proton transport occurs by the motion of hydronium ions, H₃O⁺. Water is necessary in order to facilitate proton conduction. Loss of water immediately results in degradation of the conductivity. Moreover, this degradation is irreversible—a simple reintroduction of water to the system does not restore the conductivity. Thus, the electrolyte membranes of these hydrated polymer-based fuel cells must be kept humidified during operation. This introduces a host of balance-of-plant needs for water recirculation and temperature control.

A second limitation derives from the need to maintain water in the membrane. In order to maintain hydration, the temperature of operation cannot exceed 100°C without cell pressurization. High temperature operation could be desirable, however, to increase catalyst efficiency in generating protons at the anode (in both H₂ and direct methanol fuel cells) and to improve catalyst tolerance to carbon monoxide (“CO”). CO is often present in the fuel that is used in the fuel cells. The CO can poison the precious metal catalysts. This is particularly problematic in indirect hydrogen/air fuel cells for which hydrogen is generated on site. High temperatures also benefit the reduction reaction on the cathode.

Another limitation of hydrated polymer electrolytes occurs in applications in methanol fuel cells. These polymers can be permeable to methanol. Direct transport of the fuel (i.e. methanol) across the membrane to the air cathode results in losses in efficiency.

Alternate proton conducting materials, which do not require humidification, which can be operated at slightly elevated temperatures, and/or which are impermeable to methanol, are desirable for fuel cell applications.

In the field of hydrogen separation, a proton conducting membrane is utilized to separate hydrogen from other gases such as CO and/or CO₂. Palladium is often used for this application. Palladium is permeable to molecular hydrogen, but not in general to other gases. There are drawbacks to the use of this material. It is expensive and the hydrogen diffusion rate is low. It would be desirable to develop new materials which are less expensive and exhibit higher proton/hydrogen transport rates.

In general, materials utilized in other electrochemical devices such as electrolysis cells, batteries, supercapacitors, etc., include liquid acid electrolytes, which are highly corrosive, and solid polymer proton conductors, which require humidification or exhibit insufficient proton conductivity. High conductivity, high chemical and thermal stability solid membranes with good mechanical properties are desirable for all of these applications.

SUMMARY

The present specification defines a new kind of material for a proton conducting membrane. Specifically, a proton conducting material is formed using an solid acid. The solid acid can be of the general form M₃H₂(XO₃)ₙ, or MₙHₓ(XO₃)ₓ·nH₂O, where:

M is one or more of the species in the group consisting of Li, Be, Na, Mg, K, Ca, Rb, Sr, Cs, Ba, Ti and NH₄, or Cu;

X is one or more of the species in the group consisting of Si, P, S, As, Se, Te, Cr and Mn; and

a, b, c, n and t are rational numbers.
Solid acids do not rely on the presence of hydronium ions for proton transport, thus they do not require hydration for use as proton conductors.

A preferred solid acid used according to this specification is a solid phase solid acid that exhibits a superprotonic phase, a phase in which the solid has disorder in its crystal structure and a very high proton conductivity.

An embodiment uses a structural binder or matrix material to enhance the mechanical integrity and/or chemical stability of the membrane. That structural binder can be many different kinds of materials in the different embodiments. In particular, the structural binder can be a polymer, a ceramic, or an oxide glass.

Another embodiment uses an electronically conducting material as a matrix. This creates a membrane which conducts both protons and electrons.

The resulting material can be used for a proton conducting material in a device that relies on the flow of protons or the flow of both protons and electrons across a membrane, herein an "electrochemical" device e.g. a fuel cell, a hydrogen separation membrane, or a electrolysis cell.

**BRIEF DESCRIPTION OF THE DRAWINGS**

FIG. 1 shows an exemplary hydrogen/air fuel cell using an solid acid supported by a binder as its proton conducting membrane.

FIG. 2 shows an exemplary direct methanol fuel cell using an solid acid supported by a binder as its proton conducting membrane;

FIG. 3 shows a hydrogen separation membrane for the removal of CO and other gases from hydrogen;

FIG. 4 shows another type of hydrogen separation membrane made of a proton conducting composite; and

FIGS. 5 and 6 show a membrane reactor.

**DETAILED DESCRIPTION**

The present application teaches using an solid acid as a proton conducting membrane.

A solid acid can be of the general form $\text{M}_x\text{H}_y(\text{XO}_z)^t$; $\text{nH}_2\text{O}$, where:

- $\text{M}$ is one or more of the species in the group consisting of Li, Be, Na, Mg, K, Ca, Sr, Cs, Ba, Ti and NH$_4$;
- $\text{X}$ is one or more of the species in the group consisting of Si, P, S, As, Se, Te, Cr and Mn; and
- $a$, $b$, $c$, $n$ and $t$ are rational numbers; with $t$ preferably being 3 or 4 and where $\leq t$.

The solid acids used herein are compounds, such as CsHSO$_4$, whose properties are intermediate between those of a normal acid, such as H$_2$SO$_4$, and a normal salt, such as Cs$_2$SO$_4$. In general, the chemical formula of the solid acids of the type used according to the present specification can be written as a combination of the salt and the acid.

In general, solid acids are comprised of oxyanions, for example SO$_4$ or SO$_3$, SeO$_3$, SeO$_2$, SiO$_4$, PO$_4$ or AsO$_4$, etc., which are linked together via $\text{O}^-$-$\text{H}^+$-$\text{O}$ hydrogen bonds. The structure may contain more than one type of XO$_2$ or XO$_4$ group, and may also contain more than one type of M species.

Certain solid acids are solid materials at room temperature.

Many different solid acids are contemplated by this specification.

One example of a material that can be used as the solid acid is CsHSO$_4$, which is intermediate between Cs$_2$SO$_4$ (a normal salt) and H$_2$SO$_4$ (a normal acid). In this case, the solid acid can be written as $0.5\text{Cs}_2\text{SO}_4*0.5\text{H}_2\text{SO}_4$. Another example, using the same salt and the same acid, is $1.5\text{Cs}_2\text{SO}_4*0.5\text{H}_2\text{SO}_4$ to give Cs$_3\text{H}(\text{SO}_4)_2$.

Other examples are:

- CsH$_2$PO$_4$, Cs$_2$(HSO$_4$)(H$_2$PO$_4$), Cs$_2$(HSO$_4$)$_2$(H$_2$PO$_4$), Cs$_2$(HSO$_4$)$_2$(H$_2$PO$_4$)
- Cs$_2$(HSO$_4$)$_2$(H$_2$PO$_4$), Cs$_2$(HSO$_4$)$_2$(H$_2$PO$_4$)
- Cs$_2$(HSO$_4$)$_2$(H$_2$PO$_4$), TSH$_2$O$_4$. CsSeO$_4$ or Cs$_2$(HSeO$_4$)
- H$_2$PO$_4$, Cs$_2$(SeO$_4$)$_2$ (NH$_4$)$_2$H$_2$SO$_4$, (NH$_4$)$_2$(H$_2$PO$_4$)
- Cs$_3$(H$_2$PO$_4$)$_2$, NH$_2$H$_3$(H$_2$PO$_4$)$_2$, (NH$_4$)$_2$(H$_2$PO$_4$), Cs$_3$(H$_2$PO$_4$)$_2$, (NH$_4$)$_2$(H$_2$PO$_4$).

The preferred material for any specific electrochemical device depends on the application. For example, Cs$_2$(HSeO$_4$)

Another advantage is that solid acids are generally stable against thermal decomposition at elevated temperatures. The thermal decomposition temperature for some of the solid acids described in this specification, e.g., CsNaH$_2$SO$_4$, can be as high as 350°C.

Since solid acids need not be humidified, solid acid based membranes can be operated at elevated temperatures, e.g. temperatures above 100°C.

The conductivity of solid acids may be made purely protonic, or both electronic and protonic depending on the choice of the X element in the chemical formula $\text{M}_x\text{H}_y(\text{XO}_z)^t$; $\text{nH}_2\text{O}$ or $\text{M}_x\text{H}_y(\text{XO}_z)^t$; $\text{nH}_2\text{O}$. That is, by using a given amount of a variable valence element such as Cr or Mn for X, the solid acid can be made to conduct electrons as well as protons.

Another advantage is caused by the structure of the solid acids themselves. Since solid acids are dense, inorganic materials, they are impermeable to gases and other fluids that may be present in the electrochemical environment, e.g.,

- gases and hydrocarbon liquids.

The materials are also relatively inexpensive.

This combination of properties: good conductivity in dry environments, conductivity which can be controlled to be either purely proton conducting or both electron and proton conducting, impermeability to gases and hydrocarbon liquids, serviceability at elevated temperatures, e.g. temperatures over 100°C. and relatively low cost, render solid acids as useful materials for use as membranes in electrochemical devices.

Solid acids exhibit another advantageous property for applications in proton conducting membranes. Under certain conditions of temperature and pressure, the crystal structure of a solid acid can become disordered. Concomitant with this disorder is an high conductivity, as high as $10^{-2}$ to $10^{-4}$ $\Omega^{-1}\text{cm}^{-1}$. Because of the high proton conductivity of the structurally disordered state, it is known as a superprotonic phase. The proton transport is believed to be facilitated by rapid XO$_2$ and XO$_4$ group reorientations, which occur because of the disorder.

Many solid acids enter a superprotonic state at a temperature between 50 and 150°C. at ambient pressures. The transition into the superprotonic phase may be either sharp or gradual. The superprotonic phase is marked by an increase in conductivity, often by several orders of magnitude. At temperatures above the transition temperature, the
solid acid is superprotionic and retains its high proton conductivity until the decomposition or melting temperature is reached.

Solid acids that undergo a superprotionic transition include:

- Cs$_2$(HSO$_4$)$_2$(H$_2$PO$_4$), Cs$_2$(HSO$_4$)(H$_2$PO$_4$), Cs$_2$(HSO$_4$)(H$_2$PO$_4$)$_2$, Cs$_2$(HSO$_4$)(H$_2$PO$_4$)$_3$, Cs$_2$(HSO$_4$)(H$_2$PO$_4$)$_4$, Cs$_2$(HSO$_4$)(H$_2$PO$_4$)$_5$, Cs$_2$(HSO$_4$)(H$_2$PO$_4$)$_6$.

The superprotionic phases of solid acids have increased conductivity. An interesting embodiment is a solid acid operated at a temperature above the superprotionic transition temperature, and below the decomposition or melt temperature.

Despite the many advantageous properties of solid acids, problems can be encountered in trying to implement them in electrochemical devices because many solid acids are water soluble. They can also be difficult to process into large area membranes, and they often have poor mechanical properties. Some solid acids, such as CaNaH$_2$SiO$_4$ and other silicates, are not soluble in water.

Because of these difficulties, a disclosed embodiment includes a composite comprised of an solid acid embedded in a supporting matrix. The solid acid part of the composite provides the desired electrochemical activity, whereas the matrix provides mechanical support and also may increase chemical stability. Different materials are contemplated herein for use as the supporting matrix.

In light of the properties of solid acids outlined above, the preferred embodiment is a composite material comprised of a solid acid embedded in a supporting matrix and operated at a slightly elevated temperature. In such a composite, the solid acid is in its superprotionic phase, exhibits high conductivity, and provides the desired electrochemical functions; the support matrix may provide mechanical support, and it may also serve to protect the solid acid from water in the environment. A high temperature of operation can render the solid acid into its superprotionic state. A high temperature of operation can also ensure that any water present in the electrochemical device will be present in the form of steam rather than liquid water, making the H$_2$O less likely to attack the solid acid.

Hydrogen/Air Fuel Cells

A hydrogen/air fuel cell is shown in FIG. 1, in which the proton conducting membrane is a solid acid/matrix composite of the type described herein. Because the membrane need not be humidified, the fuel cell system can be simpler than one which uses a hydrated polymer membrane. The humidification system normally required for fuel cell utilizing a Nafion or related polymer membrane can be eliminated in FIG. 1. Hence, less rigid temperature monitoring and control may be used in the solid acid based system as compared with Nafion based fuel cell systems. These differences allow a less costly fuel cell system.

Because the membrane need not be humidified, the fuel cell shown in FIG. 1 can be operated at temperatures above 100°C. The tolerance of the Pt/Ru catalysts to carbon monoxide CO poisoning increases with increasing temperature. Thus, a fuel cell such as shown in FIG. 1, operated at a temperature above 100°C may withstand higher concentrations of CO in the hydrogen fuel than a Nafion based fuel cell which is typically operated at a temperature lower than 100°C.

The high temperature of operation also enhances the kinetics of the electrochemical reactions, and can thereby result in a fuel cell with higher overall efficiency than one based on Nafion or other hydrated polymers.
In FIG. 5 a membrane reactor is shown, in which a mixed proton and electron conducting membrane of the type described herein is utilized. The general reaction is that reactants A+B react to form products C+D, where D is hydrogen gas. Use of a mixed proton and electron conducting membrane in this reactor can enhance the reaction to give yields that exceed thermodynamic equilibrium values. On the inlet side of the membrane reactor, the reactants form products C+D. Under equilibrium conditions, the hydrogen concentration builds up and the forward reaction is slowed. With the use of the mixed hydrogen and electron conducting membrane, the hydrogen is immediately extracted from the reaction region via transport through the membrane, and the forward reaction is enhanced. Examples of reactions in which yield could be enhanced by using such a membrane reactor include (1) the steam reformation of methane (natural gas) to produce syngas: CH4+H2O→CO+3H2; (2) the steam reformaion of CO to produce CO2 and H2: CO+H2O→CO2+H2; (3) the decomposition of H2S to H2 and S; (4) the decomposition of NH3 to H2 and N2; (4) the hydrodeougenation of propane to polypropylene; and (5) the hydrodeougenation of alkanes and aromatic compounds to alkenes.

In FIG. 6 a second type of membrane reaction is shown, again, utilizing a mixed proton and electron conducting membrane of the type described herein. In this case, the general reaction is that the reactants A+B form the products C+D, where B is hydrogen. The hydrogen enters the reaction region via transport through the mixed conducting membrane, whereas the reactant A is introduced at the inlet to the membrane reactor, and is mixed with other species. The manner in which the hydrogen is introduced into the reactant stream (through the membrane) ensures that only the reactant A is mixed with the other species reacts with hydrogen. This effect is termed selective hydrogenation.

The mixed proton and electron conducting membranes described herein provide an advantage over state-of-the-art membranes in that the conductivity is high at temperatures as low as 100°C, and the membranes are relatively inexpensive. Selective hydrogenation at temperatures close to ambient may have particular application in synthesis of pharmaceutically important compounds which cannot with electrons. These compounds can be used in devices which exploit both the proton and electron conducting properties. The processing methods described above may be applied to prepare such composite membranes.

Another example of a composite contains a solid acid and a second type of membrane reaction is shown, in which a mixed proton and electron conducting membrane of the type described herein is utilized. The general reaction is that reactants A+B react to form products C+D, where D is hydrogen gas. Use of a mixed proton and electron conducting membrane in this reactor can enhance the reaction to give yields that exceed thermodynamic equilibrium values. On the inlet side of the membrane reactor, the reactants form products C+D. Under equilibrium conditions, the hydrogen concentration builds up and the forward reaction is slowed. With the use of the mixed hydrogen and electron conducting membrane, the hydrogen is immediately extracted from the reaction region via transport through the membrane, and the forward reaction is enhanced. Examples of reactions in which yield could be enhanced by using such a membrane reactor include (1) the steam reformation of methane (natural gas) to produce syngas: CH4+H2O→CO+3H2; (2) the steam reformaion of CO to produce CO2 and H2: CO+H2O→CO2+H2; (3) the decomposition of H2S to H2 and S; (4) the decomposition of NH3 to H2 and N2; (4) the hydrodeougenation of propane to polypropylene; and (5) the hydrodeougenation of alkanes and aromatic compounds to alkenes.

In FIG. 6 a second type of membrane reaction is shown, again, utilizing a mixed proton and electron conducting membrane of the type described herein. In this case, the general reaction is that the reactants A+B form the products C+D, where B is hydrogen. The hydrogen enters the reaction region via transport through the mixed conducting membrane, whereas the reactant A is introduced at the inlet to the membrane reactor, and is mixed with other species. The manner in which the hydrogen is introduced into the reactant stream (through the membrane) ensures that only the reactant A is mixed with the other species reacts with hydrogen. This effect is termed selective hydrogenation.

The mixed proton and electron conducting membranes described herein provide an advantage over state-of-the-art membranes in that the conductivity is high at temperatures as low as 100°C, and the membranes are relatively inexpensive. Selective hydrogenation at temperatures close to ambient may have particular application in synthesis of pharmaceutically important compounds which cannot with electrons. These compounds can be used in devices which exploit both the proton and electron conducting properties. The processing methods described above may be applied to prepare such composite membranes.

The nature of the chemical bonding in solid acids of general formula M₃H₆(XO₄)n·nH₂O or M₃H₆(XO₄)n·nH₂O where:

M is one or more of the species in the group consisting of Li, Be, Na, Mg, K, Ca, Rb, Sr, Cs, Ba, Ti and NH₄⁺; X is one or more of the species in the group consisting of Si, P, As, Se, and Te; and a, b, c, and n are rational numbers, and n can be zero.

The second approach for introducing electronic conductivity into solid acid based materials is to prepare a composite comprised of the solid acid and a second substance which has a high electronic conductivity. This second substance may be an electronically conducting polymer, such as poly(aniline), or a typical metal, such as aluminum or copper. Where the electronically conducting component is a metal, it may be advantageous to introduce a chemically and electrically inert polymer into the composite simply to serve as a binder and provide the membrane with good mechanical properties. The processing methods described above may be used to prepare such composite membranes.

valence, such as thallium, indium, lead and tin can be used for these substitutions. The solid acid so modified may be used in an electrochemical device directly, or may be combined with a supporting matrix material as described above.

In the FIG. 1 embodiment, a membrane-electrode assembly (MEA) is prepared from the CHS-PVDF composite film in which the solid acid to polymer volume ratio is 50:50. The electrodes are formed of graphite paper which is impregnated with a complex slurry of platinum powder, PVDF, the solid acid, and Nafion, suspended/dissolved in a water and isopropanol solution. After evaporation of the solvents, the electrodes so prepared are hot-pressed onto the composite membrane. The MEA is placed in a fuel cell test station at 140° C. and hydrogen is introduced at the anode and oxygen at the cathode. The open cell voltage (OCV) obtained in this manner was 0.88 V. The same type of MEA may also be used in the FIG. 2 embodiment.

EXAMPLES

Example 1

A Cs or NH₄ based solid acid such as CsHSO₄, CsHSeO₄ or Cs₂H₅(SO₄)ₓ·xH₂O is ground and mixed with a melt-processable polymer binder, such as poly(vinylidene fluoride), and hot-pressed. The result forms a solid composite membrane which is proton conducting even in dry atmospheres. The composite membrane, being comprised of two components which are substantially impermeable to fluids, may be less permeable than Nafion™.

Example 2

A Cs based solid acid such as Cs₂(HSO₄)ₓ(H₂SO₄)ₓ(H₂PO₄)ₓ(O₃), Cs₂(HSO₄)ₓ(H₂PO₄)ₓ, Cs₂(HSO₄)ₓ(H₂PO₄)ₓ or Cs₂(HSO₄)ₓ(H₂PO₄)ₓ is ground and mixed with a melt-processable polymer binder, such as poly(vinylidene fluoride), and hot-pressed. The result forms a solid composite membrane which is proton conducting even in dry atmospheres. The membrane is also less permeable to fluids than Nafion™.

Example 3

A NH₄ based solid acid such as (NH₄)ₓH(SO₄)ₓ or (NH₄)ₓH(SO₄)ₓ is ground and mixed with a melt-processable polymer binder, such as Crystar 101 thermoplastic, and hot-pressed. The result forms a solid composite membrane which is proton conducting even in dry atmospheres. The membrane is less permeable to fluids than Nafion™ and is also less expensive.

Example 4

An solid acid silicate of general formula MₙH₂SiO₄ₓ such as CaNaH₂SiO₄, CsHSiO₄, (NH₄)HSiO₄ is used as a membrane. Some of these materials are water insoluble and may have sufficient structural integrity that a binder is not required in some applications.

Example 5

A Cs or NH₄ based solid acid, such as CsHSO₄, Cs₂(HSO₄)ₓ(H₂PO₄)ₓ, Cs₂H₅(SO₄)ₓ·xH₂O or (NH₄)ₓH(SO₄)ₓ is the prepolymer of a resin such as "castoglas", a commercial product from Buchler, Inc. The polymerization/crosslinking catalyst is added to the mixture, and a solid composite membrane so formed. The in situ polymerization/crosslinking can lead to a higher impermeability than composites formed by melt-processing.

Example 6

A Cs or NH₄ based solid acid, such as CsHSO₄, Cs₂(HSO₄)ₓ(H₂PO₄)ₓ, Cs₂H₅(SO₄)ₓ·xH₂O or (NH₄)ₓH(SO₄)ₓ is mixed with a monomer such as dicyclopentadiene. A polymerization catalyst is then added to the mixture, and a solid composite membrane comprised of the solid acid and poly (dicyclopentadiene) is formed. The in situ polymerization of the polymer can lead to a higher impermeability than composites formed by melt-processing. Use of a NH₄ based solid acid can result in an inexpensive membrane.

Example 7

A Cs or NH₄ based solid acid, such as CsHSO₄, Cs₂(HSO₄)ₓ(H₂PO₄)ₓ, Cs₂H₅(SO₄)ₓ·xH₂O or (NH₄)ₓH(SO₄)ₓ is dissolved in water, and added to a suspension of an insoluble polymer such as poly(vinylidene fluoride) suspended in a fluid such as ethanol. The mixture is cast and the liquids (water and ethanol) allowed to evaporate. This procedure yields a composite membrane which is proton conducting even in dry atmospheres. The casting step can produce very thin membranes with thicknesses on the order of one hundred microns.

Example 8

A Cs or NH₄ based solid acid, such as CsHSO₄, Cs₂(HSO₄)ₓ(H₂PO₄)ₓ, Cs₂H₅(SO₄)ₓ·xH₂O or (NH₄)ₓH(SO₄)ₓ is ground and mixed with a ceramic, such as Al₂O₃, or an oxide glass, such as amorphous SiO₂. The mixed powders are compressed by hot-pressing. The resulting composite membrane may be stable to higher temperatures than those in which the binder is a polymer.

Example 9

A Cs or NH₄ based solid acid, such as CsHSO₄, Cs₂(HSO₄)ₓ(H₂PO₄)ₓ, Cs₂H₅(SO₄)ₓ·xH₂O or (NH₄)ₓH(SO₄)ₓ is dissolved in water. The solution is introduced into a porous membrane comprised of an inert binder such as Teflon™, SiO₂, or Al₂O₃. The water is allowed to evaporate, leaving the solid acid to fill the pores of the binder. The result is a composite membrane which is proton conducting even in dry atmospheres.

Example 10

A Cs or NH₄ based solid acid, such as CsHSO₄, Cs₂(HSO₄)ₓ(H₂PO₄)ₓ, Cs₂H₅(SO₄)ₓ·xH₂O or (NH₄)ₓH(SO₄)ₓ, which is only proton conducting, is ground and mixed with an electronically conducting polymer such as poly(anylene). The composite membrane formed can conduct both protons and electrons.

Example 11

An solid acid silicate of general formula MₙH₂SiO₄ₓ such as CaNaH₂SiO₄, CsHSiO₄, (NH₄)HSiO₄ is ground and mixed with an electronically conducting polymer such as poly(anylene). The composite membrane formed can conduct both protons and electrons.

Example 12

A proton conducting solid acid, such as CsHSO₄, Cs₂(HSO₄)ₓ(H₂PO₄)ₓ, (NH₄)ₓH(SO₄)ₓ or CaNaH₂SiO₄, and a metal, such as Ag, Au, or Cu, are ground and mixed. The mixed powders are compressed by hot-pressing. The composite membrane formed can conduct both protons and electrons, and may be stable to higher temperatures than a composite in which the electron conducting component is a polymer.
A proton conducting solid acid, such as CsHSO₄, Cs₂(HSO₄)(H₂PO₄), (NH₄)₃H(SO₄)₂ or CaNaHSiO₄, and a metal, such as Ag, Au, or Cu, are ground and mixed. A polymeric material is also added. A solid composite membrane is prepared either by hot-pressing, if the polymer is melt-processable such as poly(vinylidene fluoride), or by in situ polymerization, if the polymer is in situ polymerizable such as poly(dicyclopentadiene). The composite membrane is both proton and electron conducting, and may have superior mechanical properties to a composite containing only a solid acid and a metal.

Example 14

A mixed electron and proton conducting solid acid, such as CsHCr₃S₄O₇ or (NH₄)₃H(Cr₃S₄O₇)₂, in which one of the X elements has a variable valence, is prepared from aqueous solution, ground, and then pressed into a thin membrane. The membrane is used in an electrochemical device at a temperature above the superprotonic transition temperature and above 100°C, so that the conductivity of the solid acid is high and any H₂O that may be present in the device exists in the form of steam rather than liquid water.

Example 15

A Cs or NH₄ based solid acid, such as CsHSO₄, Cs₂(HSO₄)(H₂PO₄), CsH₃(SO₄)(H₂O) or (NH₄)₃H(SO₄)₂, is prepared from aqueous solution, ground, and then pressed into a thin membrane. The membrane is used in an electrochemical device at a temperature above the superprotonic transition temperature and above 100°C, so that the proton conductivity of the solid acid is high and any H₂O that may be present in the device exists in the form of steam rather than liquid water.

Example 16

A mixed electron and proton conducting solid acid, such as CsH₃S₄O₇ or (NH₄)₃H(Cr₃S₄O₇)₂, in which one of the X elements has a variable valence, is prepared from aqueous solution or by solid state reaction. The powder is used in an electrochemical device at a temperature above the superprotonic transition temperature and above 100°C, so that the conductivity of the solid acid is high and any H₂O that may be present in the device exists in the form of steam rather than liquid water.

Example 17

A composite comprised of one or more of the solid acids listed in Table 1 and one or more of inert binders listed in Table 2. If one or more of the components in the composite is electronically conducting, the composite membrane will be capable of conducting both protons and electrons. Electronically conducting substances are indicated.

*electronically conducting

Other modifications are within the disclosed embodiment. For example, the above has described the materials having a superprotonic transition upon heating. Certain materials may have their superprotonic transition temperature below room temperature. Thus, there may be no apparent superprotonic transition and the material would be disordered at
room temperature. These solid acids with structural disorder even prior to heating are also contemplated.

What is claimed is:

1. A proton conducting membrane, formed of a solid acid material which is of a type that transports H+ ions in a solid phase, said membrane having a structure that can be used in an aqueous environment, wherein said solid acid is Cs₂Na (HSO₄)₃.

2. A proton conducting membrane, formed of a solid acid material which is of a type that transports H+ ions in a solid phase, said membrane having a structure that can be used in an aqueous environment, wherein said solid acid is CaNaH-SiO₃.

3. A proton conducting membrane comprising:
   a solid acid material which includes the chemical form
   MₐHₐ(XO₄)₄, where a, b, c and t are non-zero integers
   and the structure has XO₄ groups linked together by hydrogen bonds; and
   a structural binder with said solid acid material wherein said structural binder is electrically conducting.

4. A membrane as in claim 3 wherein said conducting material is a conducting polymer.

5. A membrane as in claim 3 wherein said conducting material is a metal.

6. A membrane as in claim 5 wherein said metal is mixed with a polymer.

7. A membrane as in claim 3 wherein said conductor is formed by direct chemical substitution with variable valence ions.

8. A membrane as in claim 4 wherein said solid acid material is processed to include variable valence elements.

9. A proton conducting membrane, comprising:
   a solid acid material which includes the chemical form
   Cs₃H₃(SiO₄)₄, where a, b, c and t are non-zero integers
   and the structure has SiO₄ groups linked together by hydrogen bonds; and
   a structural binder for said solid acid material, forming a membrane with said solid acid material.

10. A proton conducting membrane, comprising:
    a solid acid material which includes the chemical form
    MₐHₐ(XO₄)₄, where a, b, c and t are non-zero integers
    and the structure has XO₄ groups linked together by hydrogen bonds; and
    a structural binder for said solid acid material, forming a membrane with said solid acid material
    wherein said solid acid is of the general formula MₐHₐ(XO₄)₄, where;
    the X material is from the group consisting of Si, P, S, As, Se, or Te
    wherein M is Cs, and wherein said solid acid material is water insoluble.

11. A proton conducting membrane, comprising:
    a solid acid silicate which is one of CaNaHSiO₄, Cs₃HSiO₄, or (NH₄)₂Fe₂SiO₄.
