Main chain thermotropic liquid crystal esters, ester-imides, and ester-amides were prepared from AA, BB, and AB type monomeric materials and were end-capped with phenylethynyl-, phenylmaleimide-, or nadimide reactive end-groups. The resulting reactive end-capped liquid crystal oligomers exhibit a variety of improved and preferred physical properties. The end-capped liquid crystal oligomers are thermotropic and have, preferably, molecular weights in the range of approximately 1000–15,000 grams per mole. The end-capped liquid crystal oligomers have broad liquid crystalline melting ranges and exhibit high melt stability and very low melt viscosities at accessible temperatures. The end-capped liquid crystal oligomers are stable for up to an hour in the melt phase. These properties make the end-capped liquid crystal oligomers highly processable by a variety of melt process shape forming and blending techniques including film extrusion, fiber spinning, reactive injection molding (RIM), resin transfer molding (RTM), resin film injection (RFI), powder molding, pultrusion, injection molding, blow molding, plasma spraying and thermo-forming. Once processed and shaped, the end-capped liquid crystal oligomers were heated to further polymerize and form liquid crystalline thermosets (LCT).

LIQUID CRYSTALLINE THERMOSETS
FROM ESTER, ESTER-IMIDE, AND
ESTER-AMIDE OLIGOMERS

This application claims the benefit of U.S. provisional application No. 60/232,504, filed Sep. 13, 2000.

ORIGIN OF THE INVENTION

This invention was made by employees of the United States Government and may be manufactured and used by or for the Government for governmental purposes without the payment of any royalties thereon or therefor.

1. Field of the Invention

The present invention relates generally to liquid crystalline polymers and liquid crystal thermosets. Specifically, the invention relates to liquid crystalline ester, ester-imide, and ester-amide oligomers and the improved physical properties of such species when they are end-capped with phenylacetylene, phenylmaleimide, or nadimide terminated monofunctional reactants. The invention also relates to the ability to process liquid crystal polymers and their use in melt process shape forming and blending techniques such as film extrusion, fiber spinning, reactive injection molding (RIM), resin transfer molding (RTM), resin film injection (RFI), powder molding, pultrusion, injection molding, blow molding, and thermo-forming.

2. Description of the Related Art

High molecular weight linear ester-based thermotropic liquid crystalline polymers (TLCPs) are known in the literature. Non-end-capped TLCP copolymers are taught by Kohluss and Jackson in U.S. Pat. No. 3,778,410 and U.S. Pat. No. 3,804,805. TLCP copolymers with non-reactive phenylester and ethylenic end-cap groups, that can only be thermoret at elevated temperatures via oxidative backbone crosslinking, are taught by Calundann in U.S. Pat. No. 4,067,852 and U.S. Pat. No. 4,161,470 and Calundann et al. in U.S. Pat. No. 4,083,829. McCarthy et al. in U.S. Pat. No. 5,319,064 and Plotzker et al. in U.S. Pat. No. 5,688,895 teach high molecular weight liquid crystalline poly(ester-imide), Alanko et al. teach, in U.S. Pat. No. 5,843,541, high molecular weight poly(ester-imide), and Hisgen et al. teach high molecular weight poly(ester-imide) in U.S. Pat. No. 4,762,906. The McCarthy et al., Plotzker et al., Alanko et al. and Hisgen et al. patents do not teach polymers with melt viscosities in the range of approximately 1 to approximately 250 poise, and the claimed high molecular weight liquid crystalline polymers have neither reactive end-caps nor rubber characteristics above \( T_g \).

3. Description of the Invention

This process results in undesirable volatiles. Thermosets have been prepared from thermotropic liquid crystalline polymers. Uryu and Kato teach, in U.S. Pat. No. 4,710,547, thermotropic liquid crystal thermosets (TLCTs) via incorporation of trifunctional cross-link units into the TLCPs in order to immobilize the anisotropic melt. Haider et al. teach, in U.S. Pat. No. 5,216,073, a moldable composition by blending a liquid crystal polymer with an epoxy-functionalized rubber. In U.S. Pat. No. 4,654,412, Calundann et al. teach incorporation of stilbene and tolane type difunctional monomers into the backbone of main chain wholly aromatic liquid crystalline polymers in which cured shaped articles made of these polymers were prepared by backbone crosslinking using a maleic anhydride dipping procedure requiring an undesirable second process step.

Lubowitz et al. teach, in U.S. Pat. Nos. 4,661,604, 4,684,714, U.S. Pat. No. 4,739,030, U.S. Pat. No. 4,851,501, and U.S. Pat. No. 5,550,204 self-reactive end-cap monomers to prepare oligomeric polymer resins, including polyesters. Lubowitz et al., however, do not teach using the claimed end-caps with liquid crystal oligomers. Lubowitz et al. further, teach the use of end-cap groups that will not survive the melt condensation polymerization conditions. Finally, Lubowitz et al. do not teach materials with melt viscosities in the range of approximately 1 to approximately 250 poise at a shear rate of 100 radians/second.

Bilow et al. teach, in U.S. Pat. No. 3,864,309, polynime oligomers end-capped with terminal acetylene or cyano groups. Bilow et al.’s use of the term “oligomer” is inconsistent with our present use of the term “oligomer.” Bilow et al. teach low molecular weight pure end-capped imides as opposed to low molecular weight polyimide oligomers, the Bilow et al. patent teaches end-capped backbone structures of only one unit wherein an entire sample contains only molecules of the same length and molecular weight. Bilow et al. teach the use of end-cap groups that will not survive melt condensation polymerization conditions. Finally, Bilow et al. teach materials that are neither liquid crystalline nor have melt viscosities in the range of approximately 1 to approximately 250 poise at a shear rate of 100 radians/second.

Reinhardt et al. teach, in U.S. Pat. No. 4,513,131, phenylacetylene end-capped low molecular weight pure aryl-ethers as opposed to the polyester, poly(ester-amide), and poly(ester-imide) oligomers. Reinhardt et al. teach materials that are liquid crystals. Reinhardt et al. teach at least one type end-capped polymer backbone.

SUMMARY OF THE INVENTION

Based on what has been stated above, it is an objective of the present invention to prepare high-performance end-capped oligomers via melt condensation techniques. These end-capped linear oligomers have wide temperature range while maintaining the liquid crystal state and properties. The melt processed linear oligomers are highly reduced in flow and exhibit rheological behavior similar to that of the liquid crystal state. The melt processed oligomers can be prepared using high temperature and pressure, and can be processed by injection molding.

Another objective of the present invention is to prepare high-performance end-capped oligomers by the liquid crystal state, and to develop a process for preparing these oligomers.

The process for preparing the high-performance oligomers involves melt processing of the oligomers in the liquid crystal state, followed by molding under high pressure and temperature conditions. The resulting oligomers are suitable for various applications such as epoxy resins, adhesives, and coatings.

50. Another objective of the present invention is to prepare high-performance oligomers by the liquid crystal state, and to develop a process for preparing these oligomers. The process for preparing the high-performance oligomers involves melt processing of the oligomers in the liquid crystal state, followed by molding under high pressure and temperature conditions. The resulting oligomers are suitable for various applications such as epoxy resins, adhesives, and coatings.
can be identical or different on any given end-cap unit provided they do not interfere with the melt condensation synthesis of the liquid crystal oligomers or the higher temperature curing step. Possible R' substituents include hydrogen, lower alkyl groups (preferably containing four or less carbon atoms) such as methyl, ethyl, propyl, and butyl groups, aryl groups (preferably containing six to ten carbon atoms) such as phenyl or naphthyl groups, lower alkoxy groups such as methoxy, ethoxy, and propoxy, lower arlyoxy groups such as phenoxy or benzyloxy, or halogen groups (i.e. fluoro, chloro, bromo, or iodo groups). Other phenylacetylene end-cap derivatives include 4-phenylethynyl-phenol and 4-phenylethynylene-benzoic acid.

The present invention end-capped liquid crystal ester, ester-imide, and ester-amide oligomers can be modified by means of conventional additives, used in conventional amounts, of stabilizers, oxidation inhibitors, agents against thermal and ultraviolet light decomposition, lubricants, mold release agents, colorants such as dyes and pigments, fibrous or pulverulent fillers and reinforcing agents, nucleating agents, and/or plasticizers.

DETAILED DESCRIPTION OF THE INVENTION

Within the scope of the present invention, the term “oligomer(s)” and “oligomer mixture(s)” designate mixtures of varying backbone length liquid crystal polymers, of maximally 500 repeat units, within the weight range of approximately 1000 to approximately 15,000 grams per mole that are not isolated as discreet molecular weight polymers.

The term “pure” designates liquid crystal compounds in which all molecules of a given sample are of the same length and molecular weight. The terms “high weight” and “high molecular weight” designate polymers and mixtures of polymers in which additional increases in polymer length and weight have no effect on the physical properties, including processability, of the polymers and mixtures.

Linear liquid crystal polymers (LCPs) exhibit higher degrees of molecular order while in the molten state than to well-defined end-capped liquid crystal oligomers. The ability of these species to maintain molecular order in the molten state has pronounced effects on the solid state physical properties of this class of polymers. Specifically, liquid crystalline polymers exhibit molecular order in the solid state and lower melt viscosities at higher molecular weights. The improved molecular order in the solid state makes liquid crystal polymers desirable for uses in shape molded composite materials. Despite LCPs exhibiting reduced melt viscosities, the melt viscosities have not until now been sufficiently low to make higher weight LCPs amenable to improved melt process shape forming and blending techniques such as film extrusion, fiber spinning, reactive injection molding (RIM), resin transfer molding (RTM), resin film injection (RFI), powder molding, pultrusion, injection molding, blow molding, plasma spraying, and thermo-forming.

Linear thermotropic liquid crystals typically have very high melting points and molecular weights that limit their ability to be melt processed. Once formed, however, the polymers typically have very high melting points and molecular weights that limit their ability to be melt processed. The present invention involves the preparation of liquid crystal oligomers of relatively moderate weight and length via traditional melt state condensation techniques. The liquid crystal oligomers were end-capped in the melt state with phenylacetylene, phenylmaleimide, or nadimide terminated monofunctional reactants. These end-caps are stable in the melt state condensation conditions needed for preparing the liquid crystal oligomers. The end-caps were chosen so as to polymerize with each other at temperatures above the range used for the melt condensation preparation of the oligomers but below that which will induce cross-linking of the liquid crystal backbone.

The resulting end-capped LCTs display many superior and improved properties to their non-end-capped high molecular weight analogs that are non-obvious and unanticipated in the literature. Among these properties are: unusually lowered melt viscosities for these weight polymer species compared to non-end-capped higher molecular weight analogs and comparable and/or superior to previously end-capped lower weight non-oligomeric species (end-capped single pure molecules), stability of melt viscosities at elevated temperatures for extended periods of time relative to previous liquid crystalline products, and reduced brittleness (i.e. rubber behavior) above the glass transition temperature.

The end-capped liquid crystal oligomers exhibit lower melt viscosities than the corresponding non-end-capped high weight analogs. Being polymeric, the end-capped liquid crystal oligomers exhibit superior physical properties relative to well-defined end-capped low weight pure liquid crystal esters. This class of end-capped liquid crystal oligomers, therefore, exhibits improved melt processability relative to higher weight analogs while maintaining the benefits of being polymeric relative to well-defined end-capped low weight pure liquid crystal esters. In many instances, the lowered melt viscosity can be maintained for extended periods of time relative to the non-end-capped higher weight analogs and comparable and/or superior to the end-capped low weight pure liquid crystal esters. Lowered melt viscosities make this new class of liquid crystal polymers more amenable to melt processing. For the first time, higher weight liquid crystal oligomers can be used effectively in melt process shape forming and blending techniques.
Once melt processed and shaped, the end-capped liquid crystal oligomers were cured at elevated temperatures (temperatures above that used for the melt state condensation) resulting in liquid crystal thermosets. This second step causes the end-caps to react with one another and further increases the molecular weight of the liquid crystal polymers. Traditionally, heat curing of polymer molds is carried out at temperatures sufficiently high to induce cross-linking of the polymer backbone. Cross-linking of the backbone, however, often makes the cured product brittle. In the present invention, the reactions between the end-cap units depicted in FIGS. 1, 3 and 5 cause liquid crystalline polymers that behave as rubbers when elevated above their glass transition temperatures rather than becoming brittle.

Method of Preparation

The “backbones” of the end-capped liquid crystalline ester, ester-imide, or ester-amide oligomers were prepared from a reaction between varying quantities and combinations of one or more aromatic, heterocyclic or aliphatic dicarboxylic acids, aromatic, heterocyclic or aliphatic diols aromatic, heterocyclic or aliphatic diamines, hydroxybenzoic acids and aminobenzoic acids. The preferred embodiments of the end-capped ester, ester-imide, and ester-amide oligomers backbones are depicted in FIG. 1 wherein R is the structural units depicted in FIG. 2 and Ar is the structural units depicted in FIG. 3 and X is the structural units depicted in FIG. 4. The preferred general methods of preparation of the end-capped ester, ester-imide, and ester-amide oligomers are presented in FIGS. 5, 6, and 7 wherein R1, R2, and R3 can be identical, different, or are the structural units depicted in FIG. 2 and Ar1, Ar2, and Ar3 can be identical or different and are the structural units depicted in FIG. 3 and X is the structural units depicted in FIG. 4. E-Y represents end-cap units I, II, and/or III that can be prepared by methods available in the literature, wherein Y can be a carboxy, hydroxy, amino group or any reactive analog thereof (e.g., acetoxy, propionoxy, butoxy, etc.), or an esterified carboxy group (e.g., methylbenzoate, ethylbenzoate, phenylbenzoate, etc.) and the R’ substituents can be identical or different on any given end-cap unit provided they do not interfere with the melt condensation synthesis of the liquid crystal oligomers or the higher temperature curing step. Possible R’ substituents include hydrogen, lower alkyl groups (preferably containing four or less carbon atoms) such as methyl, ethyl, propyl, and butyl groups, aryl groups (preferably containing six to ten carbon atoms) such as phenyl or naphthyl groups, lower alkoxy groups such as methoxy, ethoxy, and propoxy, lower arylxy groups such as phenoxy or benzoxy, or halogen groups (i.e. fluoro, chloro, bromo, or iodo groups). The stoichiometric amounts of each reactant and end-cap group can be varied to prepare oligomers of varying size, weight, characteristic and chemical content. The reactions depicted in FIGS. 5, 6, and 7 are generally performed at between approximately 140°C to approximately 350°C. The melt viscosities of the end-capped ester, ester-imide, and ester-amide oligomers are lower than their non-end-capped analogs.

Preparation of Reactive End-Caps

The following specific examples are provided for illustrative purposes. These examples do not serve to limit the scope of the invention.

EXAMPLES

Phenylacetylene Terminated Carboxylic Acid; PE-COOH

Into a 250 mL two-neck round bottom flask equipped with a mechanical stirrer, condenser and a nitrogen gas inlet was placed 4-aminobenzoic acid (8.0 g, 58 mmol), 4-phenylmethylnaphthalic-anhydride (14.5 g, 58 mmol) and 150 mL glacial acetic acid. This mixture was stirred at 25°C for 1 hour after which the temperature was raised to reflux for 12 hours. The reaction mixture was cooled to 25°C and the precipitated product was collected by filtration, washed twice with hot ethanol and dried under vacuum at 100°C for 8 hours.

Phenylacetylene Terminated Acetoxy Phenol; PE-OAc

Into a 250 mL two-neck round bottom flask equipped with a mechanical stirrer, condenser and a nitrogen gas inlet was placed 4-aminophenol (6.3 g, 58 mmol), 4-phenylmethylnaphthalic-anhydride (14.5 g, 58 mmol) and 200 mL glacial acetic acid. This mixture was stirred at 25°C for 1 hour after which the temperature was raised to reflux for 12 hours. The reaction mixture was cooled to 25°C and the precipitated product was collected by filtration, washed twice with ethanol and dried under vacuum at 50°C for 8 hours.

The dried end-cap products were refluxed in 150 mL acetic anhydride for 5 hours. Yellow crystals precipitated upon cooling and were collected by filtration, washed with ethanol and dried under vacuum at 80°C for 8 hours.

Other end groups were made using similar procedures. The yields and thermal analysis results (differential scanning calorimetry) of all compounds are summarized in Table 1.

#### Preparation of End-Capped Liquid Crystal Oligomers

**Example 1**

A 100 mL 3-neck round bottom flask was charged with 4-acetoxybenzoic acid (45.1 g, 0.25 mol), 6-acetoxy-2-naphthoic acid (38.4 g, 0.17 mol), PE-COOH (2.43 g, 6.6 mmol), PE-OAc (2.52 g, 6.6 mmol) and 4 mg potassium acetate. The flask was equipped with a sealed glass paddle stirrer, a nitrogen inlet tube and an insulated distillation head. The flask was purged with nitrogen gas, and the reaction mixture was heated over a 3 hour period on a woods metal bath, under a slow stream of nitrogen, with the reaction temperature being increased from 150° C. to 300° C. At this point the temperature was increased to 310° C. over 30 minutes and a vacuum was slowly applied for 25 min. The opaque melt was cooled to room temperature and the product (6HBA/4HNA-9PE) was broken from the flask and ground into a fine powder.

Characterization of End-Capped Liquid Crystal Oligomers

The end-capped liquid crystal oligomers were characterized using melt rheology, thermogravimetric analysis (TGA) and differential scanning calorimetry (DSC). All results are summarized in Tables 2 and 3.
With exception of the ester oligomers with aliphatic spacers, all oligomers formed films that did not flow under stress and appeared nematic in nature after curing. Films that have a low concentration of reactive end groups behave more elastic above their Tg, while the films with high concentrations of reactive end groups are more brittle in nature. Isotropization temperatures could not be observed for the wholly aromatic oligomer series. Mechanical test data are shown in Tables 4 and 5.

Note: The heating rate for TGA experiments was 2.5° C. min⁻¹ and a heating rate of 10° C. min⁻¹ was used for the DSC experiments. The TGA samples were cured at 350° C. for 1 h. prior to the measurement. The DSC samples were heated to 310° C. and held for 1 h. prior to the second heat.

Melt Processing Examples of End-Capped Liquid Crystal Oligomers

Thin films were prepared by heating 7HBA/3HNA-9PE, heated with 10° C./min. to 370° C. and were held at this temperature for 1 hour to allow the reactive end groups to react. The norbornene and phenylmaleimide end groups react at temperatures between 250° C. and 400° C. The phenylacetylene end groups are more stable in the melt and no significant end group chemistry could be observed below 310° C., i.e. no increase in melt viscosity could be observed.

Example IX

Composite Laminate Film

One ply of kapton film was placed on a metal plate and 25 grams of (6HBAI4HNA-5PE) was spread evenly on top of the kapton film. Four plies of plain weave IM-7 graphite cloth was placed above the powder, followed by two plies of 0.0025" Teflon bleeder/breather cloth. FIG. 8 is a composite laminate lay-up configuration of the end-capped liquid crystal oligomers. The entire lay-up was contained in a metal dam and was vacuum bagged utilizing a standard vacuum
bagging process for high temperature polyimides. The (6HBA/4HNA-9PE)/IM-7 cloth was heated to 482°F with 5° Hg of vacuum and held for one hour. During the hour hold, the viscosity of the resin decreased and was forced up through the plain weave cloth via the 5° Hg of vacuum. After 60 minutes at 482°F, the vacuum was increased to 20° Hg and the temperature was ramped to the final cure temperature of 700°F. As the temperature reached 600°F, the part was held for 30 minutes to allow the reactive end groups (PE) to react and then the laminate was cooled to ambient temperature while maintaining full vacuum. At ambient temperature, the mold was removed from the vacuum bag and the laminate was removed from the metal dam. FIG. 9 is schematic of the cure cycle for the to ASTM D 1002. The results are summarized in Table 6.

We claim:

1. An oligomer mixture with self-reactive end-caps comprising the general structure

\[ Z \]

wherein

E and E' are

2. An oligomer mixture with self-reactive end-caps comprising the general structure

\[ Z \]

wherein Ar is
3. An oligomer mixture with self-reactive end-caps comprising the general structure

wherein
E and E' are

Z is

wherein Ar₁ and Ar₂ are

and Z is selected from the group consisting of

where Ar₁ and Ar₂ are

and Ar₂ is
