A hollow core composite assembly 10 is provided, including a hollow core base 12 having at least one open core surface 14, a bondable solid film 22 applied to the open core surface 14, at least one dry face ply 30 laid up dry and placed on top of the solid film 22, and a liquid resin 32 applied to the at least one dry face ply 30 and then cured.

7 Claims, 3 Drawing Sheets
Applying a bondable solid film
to the open core surface
of a hollow core base

Applying an adhesive layer
and solid film combination
to the open core surface

Curing the solid film
to the open core surface

Laying up dry at
least one dry face ply
on top of the solid film

Applying a liquid resin
to the at least one dry face ply

Curing the hollow core
composite assembly

FIG. 4
LIQUID MOLDED HOLLOW CELL CORE COMPOSITE ARTICLES

BACKGROUND OF THE INVENTION

The technical field of which the present invention is a part relates generally to hollow cell core composite articles and more particularly to a liquid molded honeycomb core composite articles.

SUMMARY OF THE INVENTION

It is, therefore, an object of the present invention to provide a liquid molded hollow core composite assembly for use in low weight/high strength articles. It is a further object of the present invention to provide a liquid molded hollow core composite assembly that can be manufactured without resulting in undesirable increases in composite assembly weight or manufacturing time and cost.

In accordance with those and other objects of the present invention, a hollow core composite assembly is provided. The hollow core composite assembly includes a hollow core base including at least one open core surface. The hollow core composite assembly further includes a barrier material in contact with the open core surface to prevent penetration of the hollow core surface during liquid molding processes. The barrier material includes a solid film affixed to the open core surface through the use of an adhesive layer positioned between the solid film and the open core surface.

Other objects and features of the present invention will become apparent when viewed in light of the detailed description of the preferred embodiment when taken in conjunction with the attached drawings and appended claims.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is an exploded view illustration of an embodiment of a hollow core composite assembly in accordance with the present invention;

FIG. 2 is an exploded view of an alternate embodiment of a hollow core composite assembly in accordance with the present invention;

FIG. 3 is an exploded view of an alternate embodiment of a hollow core composite assembly in accordance with the present invention; and

FIG. 4 is a flow-chart illustration of a method of producing a hollow core composite assembly in accordance with the present invention.

DESCRIPTION OF THE PREFERRED EMBODIMENT(S)

Referring now to FIG. 1, which is an illustration of an embodiment of a hollow core composite assembly 10 in
accordance with the present invention. The hollow core composite assembly 10 is intended for use within the aeronautics and spacecraft industry, although it is contemplated that the present invention may be utilized within a wide variety of fields. The hollow core composite assembly 10 provides a lightweight and cost effective method of providing structural assemblies for use in aircraft and spacecraft design.

The hollow core composite assembly 10 includes a hollow core base 12. A wide variety of hollow core base 12 embodiments are known within the prior art. One such embodiment is a honeycomb core. The advantage of hollow core bases 12 is that they provide a low weight/high strength structure popular within the aeronautics field. A traditional disadvantage to such hollow core bases 12 is that they commonly contain at least one open core surface 14 where the hollow cores 16 are exposed. This open core surface 14 provides access to the hollow cores 16 and can provide a mechanism for liquid resin from the resin transfer molding process or vacuum assisted resin transfer molding process, to penetrate the hollow core base 12 and thereby suffer losses to its weight benefits. Although it is possible for a hollow core base 12 to have a single open core surface 14, commonly a hollow core base 12 will have an upper open core surface 18 and a lower open core surface 20.

The present invention seals and protects the open core surfaces 14 through the use of a bondable solid film 22 applied to the open core surfaces 14. A variety of bondable solid films 22 are contemplated by the present invention. One embodiment contemplates the use of a polysulphone (PSU) film. Other embodiments include, but are not limited to, bondable solid films 22 such as forms of, polyethyleneterephthalate (PET), nylon, thermoplastic polymer materials, metal foils, thermoset film materials, and urethane film materials. The primary characteristic of the solid bondable film 22 is to be imperious to penetration of the liquid resin of choice in the composite liquid molding process (such as vinyl ester, polyester epoxies, phenolids, cyanate esters, etc.) and bondable to the hollow core base 12 with or without the addition of an adhesive. The solid bondable film 22 provides a barrier to prevent subsequent liquid molding materials from penetrating the hollow cores 16 and thereby compromising the integrity of the hollow core composite assembly 10.

One novel embodiment contemplates the use of polyetherketoneketone (PEKK) as the solid bondable film 22. The use of PEKK provides a variety of advantages over many films when the hollow core composite assembly 10 is for use in unique applications. One advantage, is that the PEKK film has a relatively low dielectric constant. This can be an important factor when the hollow core composite assembly 10 is intended for use within low observable aircraft. The low dielectric constant can be advantageous to designs wherein low radar profile or radar invisibility is desired. The use of PEKK also provides the advantage of providing a solid bondable film 22 with improved bonding characteristics over many solid films. This can improve and simplify the manufacturing process as well as improve the integrity of the resulting composite. Although the PEKK film 22 may be formed in a variety of dimensions, one embodiment contemplates the use of a 1.1 millimeter film.

The hollow core composite assembly 10 can further include an adhesive layer 24 positioned between the solid bondable film 22 and the open core surface 14. The adhesive layer 24, such as an adhesive film, can be utilized to assist the bonding of the solid bondable film 22 to the hollow core base 12. Although a variety of adhesive layers 24 are contemplated, one embodiment contemplates the use of FM300 film adhesive. Other contemplated adhesives include, but are not limited to, thermoplastic adhesive, hot melt adhesive, epoxy paste, BMI paste, and cyanate ester paste adhesives. It is contemplated that the solid bondable film 22 and the adhesive layer 24 are attached to the hollow core composite assembly 10 as part of the composite article perform. The thermal cycle to enhance the bonding characteristic of the solid bondable film 22 to the open core surface 14 (with or without the presence of the adhesive layer 24) can be included in the single processing cycle for the hollow core composite assembly 10 and thereby lower processing costs and cycle time. It should be understood, however, that the solid bondable film 22 may be bonded to the hollow core base 12 prior to the composite article processing cycle as a separate processing step such as pre-curing. Pre-curing refers to curing the chemically active material of a detail/subassembly prior to a future cure of a more complete assembly. In one embodiment of the present invention, the hollow core base 12 and bondable solid film 22 can be “pre-cured” prior to a liquid molding operation. During a liquid molding operation the injectioned or infused resin would then be cured.

In an alternate novel embodiment, illustrated in FIG. 2, the present invention can further include at least one outer adhesive film 26 applied to the outer surface 28 of the solid bondable film 22. A distinct and novel aspect of this embodiment, is that it can assist in improving the bondable outer surface 28 of the solid bondable film 22 in order to ensure an improved hollow core composite assembly 10 when subjected to liquid molding techniques. Prior processes often required specialized surface preparation or coatings to insure that the liquid molding techniques securely bonded to the hollow core composite assembly 10. These specialized preparations could undesirably increase the cost, process steps, and time of manufacture. The present embodiment provides a relatively quick and efficient way of improving the bondable outer surface 28 of the solid bondable film 22 without the need for expensive and time consuming processes. This may also serve to increase the range of solid bondable films 22 available for a given application.

Referring now to FIG. 3, the present invention can further include at least one dry face ply 30 laid up dry and placed on top of the solid bondable film 22. Although a single dry face ply 30 can be used, it is contemplated that a plurality of dry face plies 30 are to be used to result in a composite sandwich panel of face skins. The face ply 30 (reinforcing ply, reinforcement, etc.) of the resulting composite article may consist of carbon fiber, fiberglass, Spectra, Kevlar fabric or other high performance reinforcement material. Although a single dry face ply 30 can be used, it is contemplated that low resin content or tackified ply could be used. This type of reinforcement material and style of reinforcement form (weave, mat, yarn or tow) is dependent on the design and function of the resulting composite article and may be infinitely tailored to meet the desired need. A wide variety of dry face plies 30 are well known in the industry and can be used in combination to provide structural surfaces with unique properties. One advantage of using a plurality of dry face plies 30 is that the hollow core composite assembly 10 can be quickly and simply assembled and a single liquid molding process and all of the subsequent thermal processing, bonding steps and resin infusion can be performed simultaneously. This provides significant production cost and time advantages over many prior art methods.

Finally, liquid resin 32 is applied to the dry face ply 30, or plies, and the hollow core composite assembly 10 is cured. The liquid resin 32 wets out the dry plies 30. A single
liquid resin 32 may be applied, or a plurality of liquid resins 32 may be utilized. Once cured, the resulting assembly 10 becomes a sandwich panel of face skins surrounding a hollow core base. The liquid resin 32 is contemplated to be applied in any of a variety of known fashions. In one embodiment, it is contemplated that the liquid resin 32 is applied using a resin transfer molding process. In alternate embodiments, however, the liquid resin 32 may be applied using a variety of processes including, but not limited to, vacuum assisted resin transfer molding, vacuum infusion molding processes, etc. The liquid resin 32 may be applied to the composite article in a variety of means such as wet lay-up, resin transfer molding processes, SCRIMP, vacuum assisted resin transfer molding processes, vacuum infusion molding processes, etc. For each of the named processes, the liquid molding resin 32 is selected based on the process method, composite article end item requirements, composite article use and other factors. After the application of the liquid resin 32, the resin is allowed to set (or cure) to a rigid form permitting the composite article to be removed from the tool or mold. The method of cure is dependent upon the selected liquid resin 32. Many types of polyester resin commonly used in the marine industry cure at ambient temperatures (70 deg F) in a given amount of time, while many aerospace grade structural epoxy resins cure at 350 deg F. Each type of resin has varying cure requirements. After removal of the composite article from the tool or mold, it may undergo a post cure to enhance the resin properties or the composite article.

Referring now to FIG. 4, which is an embodiment of a method of producing a hollow core composite assembly in accordance with the present invention. The method includes applying a bondable solid film to the open core surface of a hollow core base 100. In one embodiment this includes applying an adhesive layer and solid film combination to the open core surface. The method may further optionally include curing the solid film to the open core surface. In an alternate embodiment, the solid film may be cured to the open core surface as part of a liquid molding process. The method may further include layup up at least one dry face ply on top of the solid film. It is contemplated that the at least one dry face ply may include a plurality of dry face plies. A liquid resin is then applied to at least one dry face ply 110. This may be accomplished in a single liquid resin application or may include a plurality of liquid resin applications. In addition, it is contemplated that the liquid resin ply may be applied in a variety of manners including, but not limited to, resin transfer molding, vacuum assisted resin transfer molding, and vacuum infusion molding processes. Finally, the hollow core composite assembly is cured 112. A variety of curing processes are contemplated by the present invention and may be used alone or in combination to effectuate curing base upon the curing requirements of the liquid resin, the adhesive film, and the hollow core base.

While particular embodiments of the invention have been shown and described, numerous variations and alternative embodiments will occur to those skilled in the art. Accordingly, it is intended that the invention be limited only in terms of the appended claims.

What is claimed is:
1. A method of producing a hollow core composite assembly comprising:
applying a film adhesive to an open core surface of a hollow core base;
applying an uncured solid film to said open core surface;
applying at least one liquid resin layer to said uncured solid film using a resin molding process, said at least one solid film preventing said at least one liquid resin layer from penetrating said hollow core base;
laying up dry at least one dry face ply on top of the solid film;
applying liquid resin to said at least one dry face ply; and
curing the hollow core composite assembly.
2. A method of producing a hollow core composite assembly as described in claim 1, further comprising:
curing said uncured solid film to said open core surface by said applying at least one liquid resin layer.
3. A method of producing a hollow core composite assembly comprising:
applying a film adhesive to an open core surface of a hollow core base;
applying an uncured solid film to said open core surface;
applying at least one liquid resin layer to said uncured solid film using a resin molding process, said at least one solid film preventing said at least one liquid resin layer from penetrating said hollow core base;
wherein said uncured solid film comprises polyetherketonebase.
4. A method of producing a hollow core composite assembly comprising:
applying a film adhesive to an open core surface of a hollow core base;
applying an uncured solid film to said open core surface;
applying at least one liquid resin layer to said uncured solid film using a resin molding process, said at least one solid film preventing said at least one liquid resin layer from penetrating said hollow core base;
wherein said uncured solid film comprises a polysulfone film.
5. A method of producing a hollow core composite assembly comprising:
applying a film adhesive to an open core surface of a hollow core base;
applying an uncured solid film to said open core surface;
applying at least one liquid resin layer to said uncured solid film using a resin molding process, said at least one solid film preventing said at least one liquid resin layer from penetrating said hollow core base;
wherein said uncured solid film comprises polyethylene-terephthalate.
6. A method of producing a hollow core composite assembly comprising:
applying a film adhesive to an open core surface of a hollow core base;
applying an uncured solid film to said open core surface;
applying at least one liquid resin layer to said uncured solid film using a resin molding process, said at least one solid film preventing said at least one liquid resin layer from penetrating said hollow core base;
wherein said uncured solid film is chosen from the group of nylon, thermoset film material, and urethane film materials.
7. A method of producing a hollow core composite assembly comprising:
applying a film adhesive to an open core surface of a hollow core base;
applying an uncured solid film to said open core surface;
applying at least one liquid resin layer to said uncured solid film using a resin molding process, said at least one solid film preventing said at least one liquid resin layer from penetrating said hollow core base;
applying an outer film adhesive to an outer surface of said uncured solid film.
