1 CERAMIC WITH ZIRCON COATING

This invention was made with government support under Contract No. NAS3-26385 awarded by NASA. The government may have certain rights in the invention.

BACKGROUND OF THE INVENTION

The invention relates to a composition that includes a silicon-containing substrate and a zircon coating. Silicon-containing substrates are proposed for structures used in high temperature applications, such as in heat exchangers and advanced internal combustion engines. For example, silicon-based composite ceramics have been proposed as materials for applications in combustors for supersonic commercial airplanes. In many of these applications, the silicon-containing substrates are subjected to highly corrosive environments such as oxidative or reducing atmospheres and environments containing salts, water vapor or hydrogen. Silicon-containing substrates exhibit poor oxidation resistance and may recede and lose mass under water-containing environments because of the formation of volatile species, such as silicon hydroxide [Si(OH)₄]. Hence, it is necessary to apply external environmental/thermal barrier coatings to these materials to provide protection from environmental attack at elevated temperatures.

Although an external environmental/thermal barrier coating is capable of preventing silicon-containing substrate materials from being in direct contact with the environment, typically the external coating is an oxide that has a high coefficient of thermal expansion (CTE). The difference between the coefficient of expansion (CTE) of the silicon-containing substrate and the coefficient of thermal expansion (CTE) of the external environmental/thermal barrier coating can result in high stress and lead to coating failure. Further mullite, which is used as an intermediate bond coating between a silicon-containing substrate and an oxide external coating, tends to crack because the coefficient of thermal expansion (CTE) mismatch with a silicon carbide/silicon (SiC/Si) substrate. These cracks are detrimental to the performance of the ceramic coating because they serve as fast transport paths for oxidizing and corrosive species to cause severe oxidation and corrosion at interface with the substrate. Additionally, cracks in the coating concentrate stresses. The cracks apply shear and tensile forces on the substrate to cause substrate fractures.

Thus, there is a need to provide a coating to a silicon-containing substrate that reduces stress and cracks in a ceramic composite.

SUMMARY OF THE INVENTION

The present invention provides a coating that reduces thermal expansion mismatch with a silicon-containing substrate and that can be applied as an intermediate layer or as an external coating in applications where water vapor is absent. The invention is an article that comprises a silicon-containing substrate and a zircon coating.

In another aspect, the invention relates to a method of forming an article, comprising forming a silicon-containing substrate and applying a zircon coating

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a graph illustrating comparative coefficients of thermal expansion (CTE’s) for mullite, silicon carbide (SiC), silicon (Si) and zircon (ZrSiO₄).

FIG. 2 is a photomicrograph of a silicon carbide (SiC) fiber-reinforced silicon carbide/silicon (SiC/Si) matrix composite processed by silicon melt infiltration coated with a zircon coating and yttria-stabilized zirconia external coating; and

FIG. 3 is a photomicrograph of the same composite.

DETAILED DESCRIPTION OF THE INVENTION

According to the invention, a coating composition comprising zircon is applied to a silicon-containing substrate to provide a coating with a coefficient of thermal expansion that approaches the coefficient of thermal expansion of the silicon-containing substrate.

For an infinite coating on a rigid substrate (very much thicker than the coating) stress in the coating due to thermal expansion mismatch is given by the formula:

\[
\sigma_{ms} = 2G(\alpha_s - \alpha_A)(\frac{1}{1-V_f} - 1)\\)

(1)

where \(G\) is the shear modulus of the coating. The coefficient of thermal expansion (CTE) of a coating can be designated \(\alpha_s\) and the coefficient of thermal expansion (CTE) of a substrate designated \(\alpha_A\). \(\Delta T\) is the temperature difference to which the coating and substrate are subjected and \(V_f\) is the Poisson’s ratio of a coating, which is the ratio of transverse contracting strain to elongation strain. In most cases, equation (1) is applicable to coatings on silicon-containing substrates and ceramic composites. Hence, stress generated in a coating is directly proportional to the difference between the coefficient of thermal expansion (CTE) of the coating \((\alpha_s)\) and the coefficient of thermal expansion (CTE) of the substrate \((\alpha_A)\).

FIG. 1 shows a comparison of the linear thermal expansion of mullite, zircon, silicon carbide and silicon as a function of temperature. Mullite has a higher thermal expansion than either silicon carbide (SiC) or silicon (Si). Zircon has a thermal expansion closer to that of both silicon (Si) and silicon carbide (SiC). Therefore, the stress in zircon due to thermal expansion mismatch is lower than that in mullite. The lower coefficient of thermal expansion (CTE) of zircon than that of silicon carbide (SiC) results in a compressive stress in the zircon coating during cooling. The compressive stress decreases the likelihood of coating cracking as zircon has a higher compressive strength than tensile strength.

Zircon comprises ZrSiO₄ or ZrO₂·SiO₂. It has an incongruent melting temperature of about 1680°C. Hence, it is adequate for most high temperature applications. Additionally, zircon has other advantages. A thin layer of silicon oxide (SiO₂) is formed on the surface of silicon (Si) and silicon-containing substrates due to the oxidation of silicon. Zirconia or one of various silicates can be used with the substrate as a water-resistant external coating. In these instances, a zircon intermediate coating has good chemical compatibility with both the underlying substrate and the external coating.

Suitable silicon-containing substrates include silicon carbide (SiC) and silicon nitride (Si₃N₄). The substrate can be a monolithic or composite. A composite can comprise a reinforcing fiber, particulate or whisker and a silicon-based matrix. The matrix can be processed by melt infiltration (MI), chemical vapor infiltration (CVI) or other technique. Exemplary substrates include a monolithic silicon carbide (SiC) and silicon nitride (Si₃N₄), a silicon carbide (SiC) fiber-reinforced silicon carbide (SiC) matrix composite, carbon fiber-reinforced silicon carbide (SiC) matrix composite, and a silicon carbide (SiC) fiber-reinforced silicon nitride (Si₃N₄) composite. The preferred substrate comprises a silicon carbide (SiC) fiber-reinforced silicon carbide/silicon (SiC/Si) matrix composite processed by silicon melt infiltration.
Also suitable as silicon-containing substrates are silicon metal alloys. These alloys include niobium silicon alloys, molybdenum silicon alloys and the like.

The zircon coating can be applied to the substrate by chemical vapor deposition (CVD), thermal spray or by solution techniques such as sol-gel, slurry coating or colloidal suspension coating. Precodivialing the silicon-containing substrate may be employed to improve adhesion of the zircon layer. A zirconia phase stabilizer, such as yttria (Y\text{2}O\text{3}), magnesia (MgO) or calcia (CaO) may be added to the zircon starting composition to stabilize the cubic phase and prevent volumetric changes. While allowing the conversion to zircon to take place. A post-spray annealing process at appropriate temperatures (1100 to 1350° C.) may also be used to help the coating material reach an equilibrium state to improve its stability. Materials of different coefficients of thermal expansion (CTE's), such as zirconia (ZrO\text{2}), alumina (Al\text{2}O\text{3}), cordierite (2MgO.2Al\text{2}O\text{3}.5SiO\text{2}) and/or fused silica (SiO\text{2}), may be added to the zircon to adjust its thermal expansion in a better match with a substrate is desired. A constituent starting powder of the coating and stabilizer and/or modifier may be premixed through a vigorous mechanical process, such as ball milling, to provide interlocking of the powders and prevent segregation of phases due to density differences. For the same purpose, a sol-gel or colloidal process may be employed to coat the particles of one constituent with another.

The zircon coating of the invention can be used as an external coating in applications where water vapor is absent or as an intermediate layer with an external environmental/thermal barrier coating. The thickness of the zircon coating is determined by the application and the materials of the substrate and external coating. When the zircon coating is applied as an external barrier, it should completely cover the substrate. In this application, the coating is typically applied as a plasma deposited coating to a thickness between about 1 to about 20 mils (25 to 500 microns), preferably between about 2 to about 10 mils (50 to 250 microns). For applications where the zircon coating serves as a bond layer, its thickness can be determined by the CTE mismatch between the substrate and the external barrier coating and the magnitude of stresses generated as a result of the CTE mismatch. Typically for plasma deposited coatings, the thickness is between about 1 to 10 mils (25 to 250 microns), preferably about 2 to 5 mils (50 to 125 microns).

Suitable external barrier coatings in the zircon bond coat application comprise an oxide such as yttria-stabilized zirconia, scandia-stabilized zirconia, calcia-stabilized zirconia or magnesia-stabilized zirconia. Alumina and alumina silicates such as barium strontium aluminoisilicate and calcium aluminosilicate are also typical external coating materials. Preferably, a zircon coating is applied as an intermediate layer to a composite that comprises a silicon carbide/silicon (SiC/Si) substrate and a yttria-stabilized zirconia external environmental/thermal barrier coating. The following example is illustrative of the invention.
