In Situ Multi-Species (O$_2$, N$_2$, Fuel, Other) Fiber Optic Sensor for Fuel Tank Ullage

**Abstract:** A rugged and compact fiber optic sensor system for in situ real-time measurement of nitrogen (N$_2$), oxygen (O$_2$), hydrocarbon (HC) fuel vapors, and other gases has been developed over the past several years at Glenn Research Center. The intrinsically-safe, solid-state fiber optic sensor system provides a 1% precision measurement (by volume) of multiple gases in a 5-sec time window. The sensor has no consumable parts to wear out and requires less than 25 W of electrical power to operate. The sensor head is rugged and compact and is ideal for use in harsh environments such as inside an aircraft fuel tank, or as a feedback sensor in the vent-box of an on-board inert gas generation system (OBIGGS). Multiple sensor heads can be monitored with a single optical detection unit for a cost-effective multi-point sensor system. The present sensor technology is unique in its ability to measure N$_2$ concentration directly, and in its ability to differentiate different types of HC fuels. The present sensor system provides value-added aircraft safety information by simultaneously and directly measuring the nitrogen-oxygen-fuel triplet, which provides the following advantages: (1) information regarding the extent of inerting by N$_2$, (2) information regarding the chemical equivalence ratio, (3) information regarding the composition of the aircraft fuel, and (4) by providing a self-consistent calibration by utilizing a singular sensor for all species. Using the extra information made available by this sensor permits the ignitability of a fuel-oxidizer mixture to be more accurately characterized, which may permit a reduction in the amount of inerting required on a real-time basis, and yet still maintain a fire-safe fuel tank. This translates to an increase in fuel tank fire-safety through a better understanding of the physics of fuel ignition, and at the same time, a reduction in compressed bleed air usage and concomitant aircraft operational costs over the long-run. The present fiber optic sensor can also be used as a *false-alarm-free* engine/hidden/cargo space fire detector (by measuring increased CO$_2$ and CO, and decreased O$_2$), a multi-point in situ measurement and certification system for halogenated-compound fire protection systems, and for the testing and certification of other aircraft safety sensor systems. The technology (LEW-17826-1) developed in the present sensor system is patent pending.
In Situ Multi-Species (N$_2$, O$_2$, Fuel, other) Fiber Optic Sensor for Fuel Tank Ullage

Outline

- Why Measure $N_2$, $O_2$, and Fuel?
- Fuel Ignition Studies at GRC
- Genesis for Sensor Concept – Combustion Diagnostics
- Prototype Fiber Optic Sensor System
- Some Results From Bench-top Tests
- Design of a Rugged Flight-Capable Sensor System
- Conclusions
Why Measure $N_2$, $O_2$, and Fuel?

- Absolute risk of ignition is always there – cannot be zero
- How much inerting is required for a reasonable level of safety?
- Measurement of Oxygen, Nitrogen, and Fuel Vapor (*volatiles vs. non-volatiles*) gives more accurate indication of Minimum Ignition Energy (MIE)
- The more information available, the better equipped we are to estimate potential for ignition
- Multi-Dimensional Physics-Based Response (Go/No-Go) Surface

Even if conditions in the fuel tank are susceptible to ignition, what if we can know what the maximum pressure rise is, and decide if it is dangerous?
Why Measure N₂, O₂, and Fuel? Cont’d

• Fuel vapor and O₂ concentration provides indicator of the inherent chemically-based susceptibility to ignition (kinetics)

• N₂ concentration provides indicator of inherent ability of inerting compound to absorb heat in event of ignition (thermicity)

• Direct measurement of N₂ provides accurate measure of inerting efficiency, and is best for an OBIGGS feedback control system that reduces bleed air usage and decreases fuel consumption

• Measurement of N₂/O₂/Fuel provides comprehensive picture to make informed decisions that increases aircraft safety

• Almost ALL current fuel tank ullage sensors only measure oxygen (O₂)
ASM’s Produce Nitrogen Enriched Air (NEA)

Bleed Air Input

HFM ASM’s require 14 to 35 kg/min of bleed air and 50 to 121 kW of power to inert a typical Boeing 747

Is measuring O₂ alone the best way to predict safety, and provide feedback control of OBIGGS for N₂ generation?

Multi-Dimensional Response Surface

**Notional Example of a Response Surface**

**Inputs:**

- $N_2$, $O_2$, Fuel, …
- Temperature
- Pressure (altitude)
- Ascending/Descending
- Composition of Fuel
- Humidity,…
Genesis – Laser Diagnostics in Turbulent Flames

- Raman scattering is powerful and quantitative multi-species measurement technique

- How do we make it cost-effective, practical, and reliable for an aircraft based fuel tank ullage sensor?

5-atm CH₄-Air Flame

Lean Direct Injection (LDI) Swirl Stabilized Burner

Fiber Optic Sensor System for Fuel Tank Ullage

- **Fiber Optic Probe Head**: compact and rugged design fits into tight spaces
- **Laser excitation system**: low-power 30 mW diode laser does not pose ignition danger (*equivalent to 15 µJ in 500 µs*)
- **Optical Receiver Unit**: remotely located to avoid harsh environment near fuel tank, permits easy serviceability, can accept multiple probe locations for cost-effective multi-sensor deployment

Measurement Stability in Ambient Air

- 5 Hz data rate
- Variations are due to fluctuations in laser power and can be normalized out (not shown)
- Signal obeys Poisson statistics: \( \text{RMS} = \sqrt{N} \)
  - \( N_2 = 0.79 \pm 0.0066 \) (0.8% RMS)
  - \( O_2 = 0.21 \pm 0.0028 \) (1.3% RMS)
- Simple 2-point calibration: argon for \textbf{Zero}, and dry air for \textbf{Span}

Real-Time Measurement of Nitrogen Purging Efficacy

Q.V. Nguyen (RTB), NASA GRC
Real-Time Multi-Species Chemical Gas Sensing

- True multi-species real-time gas sensing system
- Can measure fire suppressants (Halon), and CO₂ for combustion-derived inerting (CDI) applications
- Can be used as a *false-alarm-free* fire sensor for inaccessible spaces (via simultaneous detection of CO, CO₂, O₂)
Real-Time Measurement of N₂, O₂, and Fuel

Butane fuel injected into tank initially filled with air, then purged with N₂, then air

- **Fuel & oxygen** provides direct indication of the equivalence ratio
- **Nitrogen & oxygen** measurement gives direct indication of inerting
- Simultaneous measurement of nitrogen, oxygen & fuel can provide a physics-based ‘Go/No-Go’ response surface

Q.V. Nguyen (RTB), NASA GRC
CAD Model of Rugged Flight-Capable System

- Sensor Head Mounting Flange Assembly
- Main Optical Unit Assembly
- Diode Laser
- Fiber Input
- Fiber Output
- 6.35 mm (¼ in) Dia Feedthrough Fitting For Fiber Sensor

Dimensions:
- 24.1 cm (9.5 in)
- 32.5 cm (12.8 in)

Review of Features and Advantages

• The NASA-developed fiber optic aircraft fuel tank ullage sensor system is the **ONLY** one that can simultaneously and directly measure nitrogen (N₂), oxygen (O₂), and jet fuel vapor

• **Intrinsically-Safe**: No electrical wiring penetration into fuel tank, low power laser

• **Remote Monitoring**: Fiber optic technique permits remote measurement in harsh environments

• **Real-Time**: Provides rapid indication (5 sec) for safety Go/No-Go, and for OBIGGS feedback control

• **Compact & Low Power**: Small physical dimensions of probe head for easy integration, uses < 30 W power

• **Multi-Species Analysis**: N₂, O₂, CO₂, H₂O, CO, CH₄, other HC’s, H₂, Halon, etc.

• **Differentiates** Sat. vs. Un-Sat. HC’s

• **Precise**: currently has 1% precision in 5 seconds for N₂; 20 sec gives 0.5%

• **Rugged & Reliable**: system has no moving parts, is alignment-free, no consumables to wear out

• **Cost-Effective**: Monitor multiple locations (tanks) with one optics base unit located in avionics rack; cost-effective when produced in quantities comparable to aircraft

• Can be used for validation and certification of other systems

Q.V. Nguyen (RTB), NASA GRC
Conclusions

The present fiber optic sensor system provides a comprehensive picture of the real-time fuel tank inerting process and its susceptibility to ignition through a multi-dimensional ‘Go/No-Go’ response surface that *increases aircraft operational safety.*

Rather than rely on procedurally-based inerting, the present sensor system enables the use of an OBIGGS feedback control system that reduces bleed air and compressor usage which *reduces aircraft operational costs.*

Even if conditions in the fuel tank are susceptible to ignition, the comprehensive nature of the information from the present sensor system *can potentially predict the risk of damage due to pressure rise.*
Work Still Needed

• Build and test flight-hardened system on actual aircraft

• Characterize the Raman spectroscopy of jet fuels and their constituents

• Studies of MIE space for other fuels

• Studies of pressure rise

• Effect of spark shape on ignition and flame propagation

• Effect of fuel composition, humidity, other factors…
