A method of predicting aging of polymers operates by heating a polymer in the outdoors to an elevated temperature until a change of property is induced. The test is conducted at a plurality of temperatures to establish a linear Arrhenius plot which is extrapolated to predict the induction period for failure of the polymer at ambient temperature. An Outdoor Photo Thermal Aging Reactor (OPTAR) is also described including a heatable platen for receiving a sheet of polymer, means to heat the platen and switching means such as a photelectric switch for turning off the heater during dark periods.

1. PREDICTIVE AGING OF POLYMERS

ORIGIN OF THE INVENTION

The invention described herein was made in the performance of work under a NASA contract, and is subject to the provisions of Public Law 96-517 (35 USC 202) in which the Contractor has elected not to retain title.

TECHNICAL FIELD

The present invention relates to the degradation of polymers and, more particularly, this invention relates to the accelerated aging of polymers for predicting the outdoor service life of polymers.

BACKGROUND OF THE INVENTION

In the past few decades our society's increasing demands for energy have naturally resulted in increased utilization of renewable resources such as solar energy. One of the most common techniques of directly tapping solar energy involves the use of photovoltaic devices such as silicon solar cells. In general, solar cells are deployed in large solar arrays including numerous solar cells which are intricately positioned and interconnected to provide optimum electricity production.

A common problem in the use of solar cells is the requirement that they be protected from the terrestrial elements over a prolonged period of time. For example, in order to be commercially successful, solar arrays must be suitably encapsulated to achieve at least a 20-year lifetime expectancy in terrestrial environments. This has resulted in a concerted effort to develop a suitable encapsulating material to protect solar arrays from the elements over a sustained period of time.

Polymer films have been a natural choice as possible solar cell encapsulants. However, it has been a most difficult technical problem to develop proper polymers for encapsulating the solar cell arrays to protect the optically and electrically active elements from the degrading effects of typical terrestrial environments. In general, solar cell encapsulants have included three layers—the potent, an adhesive and a weather resistant layer. The layer directly surrounding the solar cell is known as the potent. The potent insulates and protects the delicate mechanical and electrical elements of the solar cell against vibrations resulting from wind, earthquakes and other possible external forces. The adhesive layer is necessary in order to secure the hard outer weather resistant layer to the relatively soft shock proof potant layer. The weather resistant layer may be composed of different materials such as a hard acrylic polymer on the top and bottom surfaces and black or silicon rubber as a sealant along the edges. This layer functions to protect the solar cell from rain, dust and other debris.

Plastics are finding increasing use in construction as decorative panels, protective films, clear panels and are increasingly being used in air and land vehicles. Many of these plastics degrade due to ultraviolet and infrared components of solar radiation, wind, rain and thermal cycling they are exposed to in the terrestrial environment.

In order to evaluate plastics for suitability for long term use, aging tests have been developed. Indoor tests use artificial light which does not accurately reproduce solar radiation. Laboratory tests are absent the effect of wind and rain and do not utilize light and dark cycling as experienced in an outdoor environment. Outdoor tests in which a panel of plastic is mounted in a fixture facing the sun do subject the sample of panel to realistic environmental conditions. However, it requires very long test periods to reach induction of a change of property such as elongation failure.

STATEMENT OF THE INVENTION

A method of accelerating the aging of polymers is provided in accordance with the invention. The method accurately predicts the outdoor service life of polymers. The plastic part is placed in the outdoor environment during the test under realistically accelerated conditions. Natural sunlight is used as the light source, thus avoiding the unpredictable effect of unnatural, artificial light sources. Furthermore, a natural light source is free, not subject to failure and unpredictable periodic replacement. All other environmental elements, such as rainfall and wind are included in the test. The outdoor environment also includes the effect of light-dark exposure experienced by any polymer in outdoor service. The method permits accurate prediction of outdoor service life from measurement of induction periods to a change in a property of the polymer under realistically accelerated service conditions.

The method of the invention is based on the discovery that heat is the accelerator, but not the initiator of photothermal degradation reactions. Aging is, therefore, accomplished by the addition of heat and natural sunlight, which is much more spectrally consistent than artificial sources. Dark cycles' reactions are also included, as are the other elements of weathering, such as moisture, wind and rainfall. The only accelerating stress is temperature, the other environmental conditions being present in their natural occurrence and intensity. The predictive capability of this type of aging may be based on simple first-order behavior, in which the log of particular property is found to be linear over time. Polymers frequently depart from this type of behavior, however, and show "induction period" behavior in which a property changes suddenly after a period of time. It has been found that the log of the induction period (for these polymers) is linear when plotted against the reciprocal absolute temperature (Arrhenius relationship).

This observation now permits heat to be used as a controllable variable in the accurate acceleration of photothermal degradation reactions. Extrapolation from high temperatures to ambient temperatures permits the induction period of polymer failure to be calculated with accuracy. This reveals the actual lifetime of the plastic part in outdoor service.

The invention also relates to an Outdoor, Photo-Thermal Aging Reactor (OPTAR) device. The device is designed to contain sealed components suitable for outdoor usage. The OPTAR includes a thermal plat assembly such as an aluminum sheet faced with a sheet of stainless steel and backed with silicone heaters. A thermocouple is mounted on the side of the platen. The platen assembly is mounted in a caulked, wooden frame and the frame is hinged so that it can be angled to face the sun. A controller controls temperature and a timer or light activated switch can be utilized to switch the heaters on only during daylight hours.

The OPTAR device is easily constructed from readily available materials. The OPTAR does not require periodic replacement of bulbs and the solar light source avoids the anomalies of failed light sources and the error of unnatural light source. The test method of
the invention is comparatively inexpensive and requires little maintenance while providing accelerated aging of polymers in a manner accurately predicting real time induction of property change.

STATEMENT OF THE PRIOR ART

The first group of patents relate to testing of polymers intended to photodegrade in the environment—the opposite characteristic desired in solar cell encapsulating films for which the OPTAR was designed. These patents disclose either outdoor solar aging experiments or indoor accelerated U.V. testing. The patents recognize the contribution of heat as an accelerator but not an initiator of photo-actinic degradative aging. The most relevant patent is Hudgin et al who at Column 13 disclose photothermal degradation and the construction of a wooden frame for holding samples of polymer in the outdoors. The ambient temperature is closely monitored. None of the patents disclose heating a polymer sheet while it is exposed to sunlight.

The collected patents disclose strip heaters secured to the rear surface of a substrate. However, these patents do not disclose any device having sheet clamping means and a hinged frame for exposing the sheet to the sun. The patents also do not show timer-controllers or optical switches for turning on the heaters during periods of sunlight.

These and many other features and attendant advantages of the invention will become apparent as the invention becomes better understood by reference to the following detailed description when considered in conjunction with the accompanying drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a side view in elevation of the heated platen assembly;
FIG. 2 is an isometric view of the OPTAR ractor showing the strip heaters partially broken away to expose the platen and thermocouple;
FIG. 3 is an exploded isometric view of the platen assembly;
FIG. 4 is an electronic block diagram of the OPTAR aging rack controller;
FIG. 5 is an illustrative curve representing the natural outdoor aging pattern for unstabilized polypropylene; and
FIG. 6 is an Arrhenius plot of log time-to-failure versus 1/K for unstabilized polypropylene.

DETAILED DESCRIPTION OF THE INVENTION

Referring now to FIGS. 1 through 4, the OPTAR device 10 is shown placed on the ground 12 in an outdoor environment with the hinges 16 angled about 45° South to face the device 10 toward the prevalent direction of the sun 18. The elevation of the device 10 is adjusted by means of a latitude adjustment screw 13 received through a threaded flange 11 attached to a frame member 50. The bottom edge of the screw 13 bears against a plate 17. The hinges 16 are also attached to the plate 17. Strips of plastic 20, are mounted on the front surface of the OPTAR device 10 by means of changing bars 19 held by releasable clamps 14, such as De-Sta-Co clamps, which flush mount the sheet on the surface of a plate 28. The OPTAR device 10 is connected to a controller 22 by a lead 24.

The heated platen assembly 15 is formed of a thick block 26 of a material having high heat capacity and conductivity such as a half-inch thick block of aluminum. The block 26 can have any shape, suitably a rectangle or square having a side dimension between 1 and 5 feet, preferably a 3 foot square sheet of material. The block 26 may be faced with a smooth mounting plate 28 such as a sheet of 16 gauge 3 or 4 stainless steel, 60 mil thick having a polished front surface 30. The mounting plate or sheet 28 may be secured to the heating block 26 by means of a layer 34 of adhesive suitably a silicone adhesive such as RTV 116. A heater 36 is applied to the rear surface of the block 26 in order to provide better thermal management of the block. It is preferred to use a plurality of strip heaters 38 each of which is applied to the surface of the block by a suitable environmentally resistant adhesive such as a layer 40 of silicone adhesive such as RTV 116. A thermocouple well 42 may be provided in one end edge 44 of the block 26. The well receives a thermocouple 46.

The heated platen assembly 15 is mounted in a rack 48 suitably formed of edge framing members 50 connected by cross brace members 52. The cross members may be indented by the thickness of the heated platen assembly 15. The outer edges of the cross members are faced with thin facing strips 25 in order to form a cavity or well for receiving the test strips 20 flush with the top surface of the facing strips 25. The frame members and facing strip should be kiln dried and painted with an environmentally resistant coating in order to be able to withstand the effects of long term usage in the environment.

Referring now to FIG. 4, OPTAR aging rack controller 21, the device 10 is operated by the controller 22 which turns the heaters on at sunrise and turns them off at sun down and controls the temperature to a pre-set temperature by means of signal generated by means of a thermocouple 46. The controller 22 has a terminal 54 for connecting the heat controlling unit to 120 volt power and a connector 58 receiving the signal wire from the thermocouple 36 and for sending power to the strip heaters. The controller unit may also contain a circuit breaker 59 indicator light 60 and a relay 62 for switching on the strip heaters 38 in order to operate the controller in cold-dark cycles and heated-light cycles. The controller contains a photoswitch 64. Optionally, the unit may be operated by a clock to operate within dark and light cycles. A photoswitch bypass 66 may be provided when a timer is used for when it is desired to operate or test the device. A thermocouple connector

2. A method according to claim 1 in which the temperature is from 50' C. to 150' C.
40
3. A method according to claim 2 in which the steps of (a) to (e) are repeated on said polymer specimens at
45
two different temperatures.
50
4. A method according to claim 3 further including the step of extrapolating the relationship of the induc-
55
periods to ambient temperature to predict the induction period of said polymers at ambient temperature.
60
5. A method according to claim 1 in which the platen assembly is mounted at an angle from 30' to 60' to the
ground.

6. A method according to claim 5 in which the platen assembly is slanted at an angle of 45' to the ground.

7. A method according to claim 6 in which the platen assembly includes a block of high heat capacity metal.

8. A method according to claim 7 in which the front surface of the platen assembly is faced with a plate of
polished metal.

9. A method according to claim 8 in which the block comprises aluminum and the plate comprises stainless
steel.

10. A method according to claim 9 in which a heating means is attached to the rear surface of the plate.

11. A method according to claim 10 in which the heating means comprises a plurality of strip heaters
attached to said rear surface.

12. A method according to claim 11 further including the steps of attaching to the block a temperature control
sensor which develops a temperature control signal, and controllably providing power to the heating means
by means of a power supply receiving the signal from the sensor and thereby controlling the temperature of
the platen assembly.

13. A method according to claim 12 in which the power supply includes switch means for selectively
turning the means off during dark periods.
14. An outdoor photothermal aging reactor for the predictive aging of polymers comprising:
   (a) a heatable platen assembly having edges and having a front surface for receiving a specimen of polymer to be tested and having a rear surface;
   (b) heating means attached to the rear surface of the platen assembly for heating the assembly and polymer specimen;
   (c) a temperature sensor applied to the platen assembly for developing a signal indicative of the temperature of the platen assembly;
   (d) a controller receiving the signal from said sensor and connected to the heating means for maintaining the temperature of the platen assembly at a constant temperature; and
   (e) stand means for disposing the front surface of the platen assembly in a preselected direction and at a preselected angle.
15. A reactor according to claim 14 further including a frame attached to the edges of the platen assembly.

16. A reactor according to claim 15 further including light-activated switch means in said controller for automatically turning off the heating means during dark periods.
17. A reactor according to claim 16 in which the switch means comprises a photoelectric sensor.
18. A reactor according to claim 17 in which the platen assembly comprises a thick block of high heat capacity metal having a front surface and a rear surface and having a well, the heating means comprises a plurality of strip heaters attached to the rear surface of the block and the temperature sensor comprises a thermostat received in the well in the block.
19. A reactor according to claim 18 further including a plate of polished metal attached to the front surface of the block.
20. A reactor according to claim 19 in which the body comprises aluminum and the plate comprises stainless steel.
