Since its founding, NASA has been dedicated to the advancement of aeronautics and space science. The NASA Scientific and Technical Information (STI) Program Office plays a key part in helping NASA maintain this important role.

The NASA STI Program Office is operated by Langley Research Center, the lead center for NASA’s scientific and technical information. The NASA STI Program Office provides access to the NASA STI Database, the largest collection of aeronautical and space science STI in the world. The Program Office is also NASA’s institutional mechanism for disseminating the results of its research and development activities. These results are published by NASA in the NASA STI Report Series, which includes the following report types:

- TECHNICAL PUBLICATION. Reports of completed research or a major significant phase of research that present the results of NASA programs and include extensive data or theoretical analysis. Includes compilations of significant scientific and technical data and information deemed to be of continuing reference value. NASA counterpart of peer-reviewed formal professional papers, but having less stringent limitations on manuscript length and extent of graphic presentations.

- TECHNICAL MEMORANDUM. Scientific and technical findings that are preliminary or of specialized interest, e.g., quick release reports, working papers, and bibliographies that contain minimal annotation. Does not contain extensive analysis.

- CONTRACTOR REPORT. Scientific and technical findings by NASA-sponsored contractors and grantees.

- CONFERENCE PUBLICATION. Collected papers from scientific and technical conferences, symposia, seminars, or other meetings sponsored or co-sponsored by NASA.

- SPECIAL PUBLICATION. Scientific, technical, or historical information from NASA programs, projects, and missions, often concerned with subjects having substantial public interest.

- TECHNICAL TRANSLATION. English-language translations of foreign scientific and technical material pertinent to NASA’s mission.

Specialized services that complement the STI Program Office’s diverse offerings include creating custom thesauri, building customized databases, organizing and publishing research results ... even providing videos.

For more information about the NASA STI Program Office, see the following:

- Access the NASA STI Program Home Page at http://www.sti.nasa.gov
- E-mail your question via the Internet to help@sti.nasa.gov
- Fax your question to the NASA STI Help Desk at (301) 621-0134
- Phone the NASA STI Help Desk at (301) 621-0390

Analytical Services & Materials, Inc., Hampton, Virginia
The use of trademarks or names of manufacturers in this report is for accurate reporting and does not constitute an official endorsement, either expressed or implied, of such products or manufacturers by the National Aeronautics and Space Administration.
This final report supplement in presentation format describes a comprehensive multi-tasked contract study to continue the development of the silver bearing alloy that was initiated under the original contract study before modification. The initial contract activity included two commercial scale ingots rolled in one inch gauge plate, now registered as aluminum alloy 2139 by the Aluminum Association. It did not include characterization of the rolled product in thicker gauges, or correlation of processing, metallurgical structure, and properties of such thicker gauges. This supplement presents the additional work conducted in this endeavor. The study was funded by the Advanced Space Transportation Programs Office and managed initially by the Metals and Thermal Structures Branch and more recently by the Advanced Materials and Processing Branch, Structures and Materials Competency. Mr. John A. Wagner served as the Technical Representative of the Contracting Officer. The primary contractor was Analytical Services and Materials Inc. and the program manager was Mr. W. Barry Lisagor, a senior scientist with AS&M. The major portion of the experimental work completed under this supplement was conducted by ALCAN Rolled Products LLC., as a principal subcontractor and the principal investigator was Dr. Alex Cho, a senior scientist with ALCAN Rolled Products.

Under the task supplement on aluminum alloy 2139, considerable progress has been achieved in raising the technology readiness level of this promising new alloy to near application status.

The additional two commercial scale ingots were processed into nominal plate gauges of two, four and six inches, and were extensively characterized in terms of metallurgical and crystallographic structure, and resulting mechanical properties. Emphasis was focused on durability and damage tolerance as well as strength and resistance to environmental degradation.

Alloy 2139 is processed by conventional stress relieve and artificial aging practices but does not require the cold deformation processing to develop attractive combinations of strength, toughness, and fatigue crack growth resistance as do conventional 2XXX alloys. This is due primarily to the fact that the strengthening phase, omega, is homogeneously precipitated upon aging, compared to theta prime in more conventional alloys which is heterogeneously precipitated and requires cold work to develop initiation sites for the aging process.

This report includes comparisons of the property combinations for this alloy and 2XXX and 7XXX alloys more widely used in high performance applications. It shows the dramatic improvement in all combinations of properties, including ballistic impact.
performance which cannot be overlooked in this potentially important application. Moreover, the properties of this alloy are retained in all gauge thicknesses, contrary to typical reductions observed in thicker gauges of the other alloys in the comparison. The advancements achieved in this study are expected to result in rapid, widespread use of this alloy in a broad range of ground based, aircraft, and spacecraft applications.
Development of Al-Cu-Mg-Ag Alloy (2139)

NASA Contract No. NNL04AB64T
with AS&M Inc.
Development of new Al-Cu-Mg-Ag based alloy (2139) plate

Contents

I. Background

II. Metallurgical attributes of the Al-Cu-Mg-Ag alloy system

III. Development of 2139 (Al-Cu-Mg-Ag alloy) wrought product
   - Effect of dispersoid forming elements

IV. Development of 2139 thick gauge plate product

V. Summary & Conclusion
I. Background

Three Alloy Groups for Aerospace Applications

- 2xxx-T8xx (T6xx)
- 7xxx-T7xx (T6xx)
- 2xxx-T3xx

Each of these groups of alloys has unique benefits and shortcomings.

For predominantly damage tolerant applications, 2xxx-T3xx products are commonly used, despite numerous shortcomings as follows:
Development of new Al-Cu-Mg-Ag based alloy (2139) plate

Damage Tolerance Capability of 2xxx alloys

Limitations of –T3xx type temper

a. Limited Product Thickness
   - poor SCC resistance for thick plate (Slow Quench)

b. Limited Product Forms
   - Very large amount of cold work by “cold rolling” is available only for thin plate

c. Limited Fabrication Process
   - Age Forming cannot be utilized.
   - Cannot be processed to “O-temper” product
     Formability of –O temper (annealed) is not available

- Therefore, it would be desirable to develop a 2xxx alloy in an artificially aged temper (T6 or T8 type temper) having DT capabilities of T3xx type temper product.
II. Metallurgical benefits of Al-Cu-Mg-Ag alloy system*

Goal: 2xxx alloy in an artificially aged temper (T6 or T8 type temper) having Damage Tolerance (DT) and Durability (D) capabilities of T3xx type temper product.

</tr>
</tbody>
</table>

**Metallurgical Attributes of Alloy 2139**

Major strengthening phase is Ω(Al2Cu) phase
- Ω phase nucleates homogeneously in the grain matrix without cold work
- This leads to less GB precipitation and reduces propensity for intergranular fracture

Contains no Zr as a dispersoid forming element
- Reduces GB precipitation

Contains Mn as a dispersoid forming element
- Reduces Planar slip to improve Toughness

*note: This part has been published in the proceedings of The 10th International Conference of Aluminum Alloys at Vancouver, Canada, June 2006
Addition of small amounts of Mg and Ag to Al-Cu alloys promotes the nucleation of plate-like precipitates known as $\Omega$ (Al$_2$Cu) phase.

</tr>
</tbody>
</table>

**Homogeneous nucleation mechanism of $\Omega$ phase**
- achieve high strength without high level of cold work prior to artificial age.
- more uniform distribution of precipitates without relying on dislocations, sub-grain and grain boundaries as nucleation sites.
- less prone to intergranular and intersubgranular fracture after artificial age
III. Effect of dispersoid forming elements in 2139−T8**

Optimization of Dispersoid Forming Element – Why Mn?

*The experiments were conducted with industrial scale trials using full plant size ingots (13,000 lbs. ingots)*

Figure 2. Fractography of B sample tested at -65°F (showing many areas with brittle fracture mode)
Alloy A(w/Mn) shows better ballistic performance, compared to Alloy B(w/Zr)

**Effect of Dispersoid on Ballistic Performance**

1 inch ga 2139-T8 plate are tested per MIL-DTL-46192C

![Graph showing ballistic performance](graph.png)

- **Note:** FSP; Fragmented Shrapnel Penetration tests  AP; Armor Piercing tests
Adding Zr to Al-Cu-Mg-Ag-Mn alloy lowers Fracture Toughness

- This indicates that Zr containing dispersoids could be detrimental to Damage Tolerance of Al-Cu-Mg-Ag alloy in T8 temper
Large particles of Mn containing dispersoids in Al-Cu-Mg-Ag-Mn alloy

Al-Cu-Mg-Ag-Mn alloy  Al-Cu-Mg-Ag-Zr alloy

Note: Both figures are under identical magnification.
Zr-containing particles at (sub)grain boundaries provide nucleation sites for Cu-containing particles

Fig. a) BF image of $\theta'$ phase ($Al_2Cu$) formed at $Al_3Zr$

Fig. b) DF image shows $\theta'$ in the matrix and $Al_3Zr$ by using $\theta'$ reflection

Note: Fig. a and Fig. b are under identical magnification.
Zr-containing particles at (sub)grain boundaries provide nucleation sites for Cu-containing particles.

- This would weaken grain boundaries by further promoting boundary precipitation and PFZ’s.

Alloys with weak g.b. strengths are more prone to intergranular fracture at very low service temperatures or at extremely high deformation rates typical of ballistic impact.
Development of new Al-Cu-Mg-Ag based alloy (2139) plate

Schematic Diagram of Deformation Mode for G.B. Failures
Homogeneous deformation requires both cross slip and planar slip mechanisms

Cross slip mechanism
- Thermally activated process
- Relying on diffusion kinetics

At Low Temp. or At Very High Deformation rate
- Cross Slip mechanism is less favored
- Planar Slip mode becomes dominant
Development of new Al-Cu-Mg-Ag based alloy (2139) plate

**Damage Tolerance Capability of 2139 plate can be evaluated by comparing to the commonly used Damage Tolerant Al alloys in Aerospace and Military Applications**

2324-T39; Lower wing plate for large commercial Airplanes (1-1.5”)
- best fatigue resistant Al alloy

2124-T8151; Ribs & Spars for Fighter plane (1”- 6”)
- best fracture toughness in 2xxx-T8xx product

7475-T7351; Lower Wing for Small Airplanes (1.5” - 4”)
- best fracture toughness in 7xxx-T7xx product

7050-T7451; Ribs & Spars for all aircraft (1.5” - 8”(10”))
- most commonly used alloy for thick gauge application for good combined properties

2519-T87; Armor plate application (1” – 6”)
- best ballistic performance

V. Summary & Conclusion

1. 2139-T8 thick plate was evaluated in three gauges, 2.0“(51mm), 4.25“(108mm) and 6.125“(156mm)

2. 2139-T8 plate did not show loss in strength as gauge increases as seen in other 2xxx-T8xx plate products. Instead, 2139-T8 plate maintained strength levels comparable to 7050-T7451 in all gauges tested

3. Combined properties of strength and fracture toughness in three testing directions exceeded those of other conventional damage tolerant Al alloys in all three gauges

4. 2139-T8 plate showed exceptionally good FCG Resistance in all three gauges

5. Over all, 2139-T8 thick plate demonstrated superior DT capability, compared to 2324-T39, 7475-T7351, 2124-T8151, and 7050-T7451 in comparable gauges tested so far - up to 6 inches thick (156mm)
This final report supplement in presentation format describes a comprehensive multi-tasked contract study to continue the development of the silver-bearing alloy now registered as aluminum alloy 2139 by the Aluminum Association. Two commercial scale ingots were processed into nominal plate gauges of two, four and six inches, and were extensively characterized in terms of metallurgical and crystallographic structure, and resulting mechanical properties. This report includes comparisons of the property combinations for this alloy and 2XXX and 7XXX alloys more widely used in high performance applications. Alloy 2139 shows dramatic improvement in all combinations of properties, moreover, the properties of this alloy are retained in all gauge thicknesses, contrary to typical reductions observed in thicker gauges of the other alloys in the comparison. The advancements achieved in this study are expected to result in rapid, widespread use of this alloy in a broad range of ground based, aircraft, and spacecraft applications.
