Catalyst compositions and methods for F-T synthesis which exhibit high CO conversion with minor levels (preferably less than 35% and more preferably less than 5%) or no measurable carbon dioxide generation. F-T active catalysts are prepared by reduction of certain oxygen deficient mixed metal oxides.
FISCHER-TROPSCH CATALYSTS

STATEMENT REGARDING U.S. GOVERNMENT SUPPORT

This invention was funded under NASA SBIR contract NNM04AA78C. The United States government has certain rights in this invention.

BACKGROUND OF THE INVENTION

Fischer-Tropsch (F-T) synthesis involves the catalytic reductive oligomerization of carbon monoxide in the presence of hydrogen as follows:

\[ n \text{CO} + 2n \text{H}_2 \rightarrow (\text{CH}_2)_n + n \text{H}_2\text{O} \]

where \( n \) is an integer and \((\text{CH}_2)_n\) represents hydrocarbons (paraffinic and olefinic), with an enthalpy of reaction of -165 kJ/mole (P. F. Schubert et al. (2001) "Studies in Surface Science and Catalysis 136: natural Gas Conversion VI."). Generally, the process converts a mixture of CO and molecular hydrogen into a mixture of hydrocarbons, including saturated hydrocarbons and olefins. Oxygenated hydrocarbons, such as alcohols, and sometimes aromatics may also be formed in a F-T process. More specifically, products of F-T processes can include gaseous, liquid, heavy oil, and wax products which can be further upgraded to various fuels (gasoline, jet fuel, diesel fuel, etc.) and other value-added hydrocarbon products. Transition metal oxides and rare earth metal oxides have generally been used to describe the F-T system and explain many of the features that have been observed. (E. Iglesia et al. (1993) in "Computer Aided Design of Catalysts," E. R. Becker, et al. (eds) Marcel Dekker, New York p. 199.)

Features of established catalytic systems for F-T synthesis are summarized hereafter. While iron and cobalt-based systems have been commercialized, iron and cobalt based systems have their origins with Fischer and Tropsch who developed alkalinized iron turning- and Kieselguhr-supported cobalt/magnesia (or thoria) catalysts (See: F. Fischer and H. Tropsch (1923) Brennst. Chem. 4:276 and F. Fischer and H. Tropsch (1925) German Patent 484,337) Iron-based and cobalt-based catalysts each have advantages for use in appropriate circumstances. Iron-based catalysts are typically employed, for example, where \( \text{H}_2/\text{CO} \) ratios are low (e.g., 0.5 to 1.5) as might be found in coal or biomass systems. In contrast, cobalt-based catalysts are more appropriately employed when \( \text{H}_2/\text{CO} \) ratios are high (>1.5) which would typically be found in natural gas-to-hydrocarbon liquids applications.

Advantages of iron-based catalysts are generally lower cost, relative insensitivity to reaction conditions, such as \( \text{H}_2/\text{CO} \) ratio and the presence of low levels of sulfide impurities; and their ability to function at low \( \text{H}_2/\text{CO} \) ratios. Cobalt-based catalysts are considerably more expensive and can show strong sensitivity to \( \text{H}_2/\text{CO} \) ratios. Cobalt-based catalysts, in general, exhibit higher overall activity and increased mechanical strength compared to iron-based catalysts. Additionally, under like conditions, cobalt-based catalysts tend to produce a distribution of hydrocarbons that is more heavily weighted toward high carbon number species (i.e., give a higher chain growth probability, \( \alpha \)) than the hydrocarbon distribution produced using iron-based catalysts. Iron-based F-T catalysts can also produce copious quantities of carbon dioxide in the F-T process, which is generally detrimental, because they can exhibit activity as an internal forward water-gas-shift catalyst.

The utility of F-T synthesis catalysts is significantly decreased if there is significant conversion of CO to \( \text{CO}_2 \) rather than to value-added hydrocarbon and oxygenated hydrocarbon products. Preferred F-T synthesis catalysts exhibit low \( \text{CO}_2 \) production particularly in combination with high \( \text{CO} \) conversion rates. An F-T catalyst may exhibit product selectivity for a desirable product composition. For example, certain F-T catalysts exhibit selectivity for production of higher molecular weight hydrocarbons, for production of low molecular weight hydrocarbons (e.g., low molecular weight olefins), for production of product with higher or lower amounts of olefinic materials, or for the production of product with higher or lower amounts of oxygenated materials (e.g., alcohols). Product selectivity of an F-T catalyst can be a significant factor in the utility of that catalyst for a given application.

The design and selection of F-T catalysts for low \( \text{CO}_2 \) production and selective applications should consider the following composition related issues: whether the mechanism of adsorption of CO to the catalyst is associative or dissociative; the relative strengths of adsorption of CO and hydrogen to the catalyst; the redox activity or ease of reduc-
stai

F-T synthesis is a process that involves an unusually high degree of interaction between reaction chemistry, catalyst proper-
ties, mass transport, reactor design, overall system inte-
gration, and economics. Catalyst selection and reactor design for a given F-T application depends upon all of these factors. For example, a cobalt catalyst may be appropriate for natural gas conversion to liquid hydrocarbons where its advantages in increased activity and longevity are beneficial. Because cobalt catalysts are sensitive to feed composition (i.e., \( \text{H}_2/\text{CO} \) ratio), the F-T system employing the cobalt catalyst may then require a water-gas-shift module upstream of the F-T catalyst when low hydrogen content sources (such as coal) are used to ensure that the appropriate \( \text{H}_2/\text{CO} \) ratio is provided. In contrast, unsupported baseline precipitated iron catalysts may not be amenable for use in slurry phase or fluidized bed reactors because of their lower mechanical strength and correspondingly high attrition rate, but would be preferred in other applications because of their relative insensitivity to \( \text{H}_2/\text{CO} \) ratio and their product selectivity charactersitics (i.e., greater selectivity for production of \( \text{C}_5 \) or higher products at low \( \text{H}_2/\text{CO} \) ratios). There is a continuing need in the art for catalysts for F-T synthesis which exhibit one or more beneficial characteristics for a given application, given \( \text{H}_2/\text{CO} \) feedstock, given reactor design, and/or a desired product composition.

A large number of F-T catalysts are known in the art. The description that follows provides a brief summary of such catalysts.

U.S. Pat. No. 6,602,921 (Manzer) reports catalysts useful in a F-T process for producing hydrocarbons which comprise certain metals, i.e., cobalt, iron, nickel, or ruthenium and combinations thereof, in addition to silver supported on a catalyst support, such as alumina, zirconia, sulfated zirconia, tungsten oxide-doped zirconia, MCM-41, zeolites, clays, titania or silica. Catalytic activity is reported to be increased by the addition of silver.

U.S. Pat. No. 6,537,945 (Singleton et al.) reports an F-T catalyst comprising a gamma-alumina support doped with lanthanum oxide and barium oxide for increased thermal stability in a slurry bubble column reaction system and containing cobalt promoted with ruthenium as the active catalyst component. Catalyst activities are expressed in g-\text{HC}/kg-cat/hr. (grams of hydrocarbon produced per gram of catalyst per hour), a measure of hydrocarbon productivity.

U.S. Pat. No. 6,515,035 reports a catalyst comprising at least one metal from Groups 8, 9 or 10 of the Periodic Table (IUPAC) impregnated on a modified alumina support that is pre-reduced using at least one reducing compound, for example selected from the group formed by hydrogen, carbon monoxide and formic acid, optionally mixed with an inert gas, for example nitrogen, in a reducing compound/(reducing compound+inert gas) mole ratio in the range of 0.001:1 to 1:1. The reduction may be carried out in the liquid phase with the catalyst suspended in an inert liquid phase.
U.S. Pat. No. 5,140,050 (Mauldin et al.) relates to catalysts useful in F-T synthesis which are prepared on binder-containing titania supports. Catastly preparation was provided. CO consumption rate (normalized to unit catalytic amount of metal or metals, on the support. Preferred metals are cobalt or a combination of cobalt with another metal.

U.S. Pat. No. 5,145,876 (Shutt) reports a F-T catalyst that is ruthenium metal supported on a high surface area support which is promoted employing bromine moieties. The preferred support is gamma-alumina. The specific source of ruthenium and bromine for catalyst preparation is disclosed as an aqueous solution of ruthenium bromide. The iron to cobalt atomic ratio of the metals in the spinel is reported to be 4:1 or more. The catalysts are reported to be useful in slurry processes for selectively producing high amount of C2 to C20 alpha-olefin materials.

U.S. Pat. No. 4,595,703 (Goldwasser et al.) relates to F-T synthesis catalysts which are slurried high surface area iron-cobalt spinels and to a slurry process employing the catalysts. The catalysts are certain unsupported Group IA or IIa metal salt-precipitated Fe-Co spinels. The patent states that carburized Fe-Co spinels prepared in an acid aqueous solution containing alpha-hydroxy carboxylic acids. The iron to cobalt atomic ratio of the metals in the spinel is reported to be 1:0 to 1.0, as well as certain unidentified perovskites compositions by spray pyrolysis or high temperature aerosol decomposition. The materials synthesized have the general stoichiometry: La1-xMyFe2O4, where M is Li, Mg, Ca, Sr, Ba or Th, and a support, used for conversion of synthesis gas with an H2:CO ratio of 0.25-4.0, preferably 0.5-1.5, to C2-C4 hydrocarbons at a pressure of 15-2000 psia and a temperature of 250-500°C. A typical gas hourly space velocity of 300 v/hr at the catalyst, followed by exposure to CO (10 mL/min/g catalyst) for 8-10 hours.

U.S. Pat. No. 4,578,665 (Goldwasser et al.) relates to F-T synthesis catalysts which are slurried high surface area iron-cobalt spinels and to a slurry process employing the catalysts. The catalysts are certain unsupported Group IA or IIa metal salt-precipitated Fe-Co spinels. The patent states that carburized Fe-Co spinels prepared in an acid aqueous solution containing alpha-hydroxy carboxylic acids. The iron to cobalt atomic ratio of the metals in the spinel is reported to be 1:0 to 1.0, as well as certain unidentified perovskites compositions by spray pyrolysis or high temperature aerosol decomposition. The materials synthesized have the general stoichiometry: La1-xMyFe2O4, where M is Li, Mg, Ca, Sr, Ba or Th, and a support, used for conversion of synthesis gas with an H2:CO ratio of 0.25-4.0, preferably 0.5-1.5, to C2-C4 hydrocarbons at a pressure of 15-2000 psia and a temperature of 250-500°C. A typical gas hourly space velocity of 300 v/hr at the catalyst, followed by exposure to CO (10 mL/min/g catalyst) for 8-10 hours.

U.S. Pat. No. 4,578,665 (Goldwasser et al.) relates to F-T synthesis catalysts which are slurried high surface area iron-cobalt spinels and to a slurry process employing the catalysts. The catalysts are certain unsupported Group IA or IIa metal salt-precipitated Fe-Co spinels. The patent states that carburized Fe-Co spinels prepared in an acid aqueous solution containing alpha-hydroxy carboxylic acids. The iron to cobalt atomic ratio of the metals in the spinel is reported to be 1:0 to 1.0, as well as certain unidentified perovskites compositions by spray pyrolysis or high temperature aerosol decomposition. The materials synthesized have the general stoichiometry: La1-xMyFe2O4, where M is Li, Mg, Ca, Sr, Ba or Th, and a support, used for conversion of synthesis gas with an H2:CO ratio of 0.25-4.0, preferably 0.5-1.5, to C2-C4 hydrocarbons at a pressure of 15-2000 psia and a temperature of 250-500°C. A typical gas hourly space velocity of 300 v/hr at the catalyst, followed by exposure to CO (10 mL/min/g catalyst) for 8-10 hours.

activity of the perovskite-based catalysts was reported to seem to be directly related to the formation of Hatgg carbides. For conversion of a mixture where $H_2/CO=2$, $SO_2(\%)$ (CO$_2$ selectivity) of 30 or more was observed.

SUMMARY OF THE INVENTION

The present invention provides catalyst compositions and methods for F-T synthesis which exhibit high CO conversion with minor levels (preferably less than 35% and more preferably less than 5%) of hydrogen, carbon monoxide, and carbon dioxide in a F-T reactor wherein the total mass flow rate of CO$_2$ out of the reactor is less than or equal to the amount of CO in the feed stream. Preferably the total mass flow rate of CO$_2$ out of the reactor is less than 90% by weight of the CO in the feed stream. More preferably, the total mass flow rate of CO$_2$ out of the reactor is less than the amount of CO in the feed gas stream. Preferably the method exhibits CO conversion greater than 20 mole% and more preferably exhibits CO conversion greater than 50 mole%. The invention also provides such catalytic processes where CO conversion is 75% or more.

In preferred embodiments employing catalysts of this invention, F-T synthesis is carried out to achieve highest CO conversion without excessive CO$_2$ generation (greater than 35% conversion to CO$_2$). F-T synthesis can be carried out using the methods and catalysts herein to obtain CO conversion of greater than 60 mole%. Methods of this invention can achieve CO conversion of between 65 mole% and 90 mole% preferably without excessive CO$_2$ production. Conversion to CO$_2$ is preferably minimized and when CO conversion is between 65 mole% and 90 mole% CO$_2$ conversion is preferably less than 35 mole% and more preferably less than 20 mole%. In addition, it is preferred that conversion to methane is minimized and preferably conversion to methane is less than 10 mole% and more preferably less than 8 mole%. In more preferred embodiments, selectivity for products other than CO, and methane is 70 mole% - 100 mole%.

In a specific embodiment the methods of this invention employ the oxygen-deficient mixed metal catalysts the invention has been exposed to a reducing gas to activate the catalyst. The unfinished catalysts of the invention have the formula:

$$AuA'vN'wBxB'yB''z0n$$

where the subscripts $u$, $v$, $w$, $x$, $y$, $z$ are normalized to give $u+v+w+x+y+z$ equal to a whole number and $n$ is a number that renders the compound charge neutral; wherein:

$A$ = Ca$^{2+}$, Mg$^{2+}$, Sr$^{2+}$, Ba$^{2+}$ or mixtures thereof; $A'$ = Y$^{3+}$, La$^{3+}$, any lanthanide metal 3+ ion, or mixtures thereof;

$A''$ = Li$^+$, Na$^+$, K$^+$, or Cs$^+$; $B$ = Fe, Co, Ni, or Ru ion or a mixture of these ions; $B'$ is a Boron, Al, Ga, or In 3+ ions or a mixture of these 3+ ions; $B''$ is a Cu$^{2+}$ or Zn$^{2+}$ ion or a mixture of these 2+ ions; $0.01 \leq \delta \leq 1.99$ $0.01 \leq \delta \leq 1.99$ $0.0 \leq w \leq 0.1$ $0.01 \leq x \leq 3.0$ $0.01 \leq y \leq 1.99$ and $0.0 \leq z \leq 1.0$.

More specifically in this formula, $u+v+w+x+y+z=4$ and $n$ is equal to 6-$\delta$, where $\delta$ is a number that makes the compound charge neutral and variables are as defined above.

The invention provides unfinished catalysts which can be activated by reduction in situ in a F-T reactor or which can be activated by reduction prior to introduction into a reactor. Preferred finished catalysts contain reduced Co, Cu, Fe, Mn, Ni, Ru or combination of these reduced metals. Unfinished catalysts of this invention include without limitation metal oxides of formulas I-IV, all of which function for F-T synthesis after activation by reduction. In specific embodiments, the catalysts of this invention are prepared from oxygen deficient mixed metal oxides which are formed by coprecipitation, glycine-nitrate combustion, impregnation, or a ceramic method. Catalysts prepared from coprecipitated metal oxides and those formed by glycine-nitrate combustion exhibit improved properties as catalysts for F-T synthesis.

The invention provides methods for reductive oligomerization of carbon monoxide (CO) in the presence of molecular hydrogen (H$_2$) which comprise the step of contacting a mixture comprising CO and H$_2$ with a catalyst which is an oxygen-deficient metal oxide that has been subjected to reduction prior to contact with the mixture. The feed mixture optionally contains CO$_2$. The method is conducted under temperature and pressure conditions selected to achieve a desired product composition. Preferred products contain hydrocarbon species having 5 or more carbon atoms (C$_5^+$. In preferred embodiments the catalytic reductive oligomerization is conducted between about 1750 C. and 3500 C. and more preferably is conducted at a temperature of 3000 C. or less.

F-T synthesis employing catalysts of this invention can be carried out over a wide range of space velocities. In particular, the method can be carried out at space velocity ranging from 1-50 mL/minute g catalyst. The method can be carried out at space velocity ranging from 10 to 40 mL/minute g catalyst.

BRIEF DESCRIPTION OF THE FIGURES

DETAILED DESCRIPTION OF THE INVENTION

Fischer-Tropsch (F-T) synthesis involves the catalytic reductive oligomerization of carbon monoxide in the presence of hydrogen to form hydrocarbons (paraffinic and olefinic). Generally, the process converts a mixture of CO and molecular hydrogen into a mixture of hydrocarbons, including saturated hydrocarbons and olefins. The product stream of F-T synthesis contains a mixture of hydrocarbon products having a range of molecular weights and including gaseous and liquid hydrocarbons at reaction temperature. The product stream when assessed at ambient temperature and pressure can contain gases, liquids and waxy hydrocarbons. The product stream may contain linear and branched hydrocarbons. The nature of the product stream generally depends upon the reaction conditions (e.g., temperature) and the catalyst employed. When the reaction is conducted at lower temperatures the product stream generally contains a majority of linear hydrocarbons. Hydrocarbons in the product stream can be characterized by the number of carbon atoms present, and can be grouped into fractions based on a common carbon number. A well-established statistical treatment (Anderson-Shultz-Flory method) that had been developed for polymerization reactions based on a step-wise chain growth mechanism has been applied for product analysis in F-T synthesis. In this treatment chain growth probability is plotted as a function of chain
length in a so-called Anderson-Shultz-Flory plot. The slope of this plot is the Anderson-Shultz-Flory value “alpha” or more simply, the alpha value, also called the growth factor. This statistical treatment can be used to characterize the distribution of hydrocarbons obtained from F-T synthesis, and the alpha value is defined as the probability of chain growth step to the next higher carbon number divided by the sum of the growth step probability plus the chain termination probability. The alpha value can be used to estimate the distribution of carbon number products and thereby the effectiveness of the process to furnish a product stream having a particular carbon number distribution. The alpha value generally depends on the catalyst and the operating conditions (temperature and pressure) and the concentrations, and the relative concentrations of feed gas components (e.g., CO, hydrogen, CO2, etc.). It is generally known in the art that F-T reaction conditions can be adjusted to vary the hydrocarbon content of the product stream. In a given F-T synthesis, alpha can be determined from analysis of the hydrocarbon products of the reaction (carbon number of hydrocarbon products and the mole fraction of the various products.) Alpha is determined as known in the art, for a single product or for a range of products. For example, alpha can be calculated from experimental data using the Flory expression:

\[ \alpha = \frac{m_n}{m_{n-1}} \]

where \( m_n \) is mole fraction of molecules containing \( n \) carbon atoms. Alpha is obtained by taking the logarithm of both sides and obtaining the slope of the In \( m_n \) line versus \( n \). The alpha values that are reported herein are average alpha for Cn hydrocarbons between \( n=6 \) and \( n=24 \).

A preferred F-T synthesis product stream is a hydrocarbon product in which the majority of hydrocarbons have more than 5 carbon atoms (herein such products are called C5+ products). These may include hydrocarbon fractions in which the majority of the hydrocarbons contain 4-12 carbon atoms, as well as hydrocarbon fractions in which the majority of the hydrocarbons contain 10-22 carbon atoms. Such fractions are a useful source for fuels such as diesel, gasoline and aviation fuels. In particular, it is preferred that the F-T product stream has high average alpha that it alpha numbers higher than 0.65. More specifically, a preferred F-T product stream for use as fuels is one that has alpha between 0.65 and 1.0. More preferably, an F-T product stream having alpha of 0.75 or more is useful for fuel applications. F-T catalysts of this invention can be employed to generate C5+ hydrocarbon products with alpha greater than or equal to 0.65. F-T catalysts of this invention can be employed to generate hydrocarbon products with alpha greater than or equal to 0.75. In general, catalysts herein can be employed to generate hydrocarbon products with alpha greater than or equal to 0.75.

More specifically, the invention provides methods for production of hydrocarbons which comprise the steps of introducing a feed stream gas comprising CO and hydrogen into a F-T reactor which reactor contains an activated catalyst of this invention. In the reactor, the feed gas is catalytically converted to a product stream. The product can be collected and characterized for the components present or remaining and generally characterized for the number of carbon atoms in the hydrocarbons produced. The reactor is operated at temperatures and pressures to obtain a desired product stream. For example, the reactor can be operated at pressures ranging from 100 psig to 1200 psig and at temperatures ranging from 175°C to 350°C. It is generally more preferred to operate at pressures between 200-600 psig. It is more preferred, particularly to obtain hydrocarbons useful for fuel applications to operate the reactor at temperatures less than about 300°C.

The feed stream gas for the F-T reactor comprises a mixture of H2 and CO (synthesis gas) H2/CO mixtures suitable as a feedstock for conversion to hydrocarbons can be obtained from various sources, for example, from light hydrocarbons, including methane or other hydrocarbons in natural gas, by means of various reforming processes, including steam reforming, auto-thermal reforming, dry reforming, advanced gas heated reforming, and by partial oxidation, catalytic partial oxidation. Other processes known in the art can be employed to generate suitable feed gas streams for F-T synthesis. Additionally, H2/CO mixtures can be obtained from biomass and/or from coal gasification. The feed stream gas may also contain off-gas recycle from an F-T reactor. It is preferred that the molar ratio of hydrogen to carbon monoxide in the feed be greater than 0.5:1 (e.g., from about 0.67 to about 2.5). More preferably, the feed gas contains hydrogen and carbon monoxide in a molar ratio of about 1.4:1 to about 2.3:1. The feed stream gas can also contain CO2. The feed stream gas preferably contains only low concentrations of compounds or elements that can detrimentally affect catalyst activity. It may be necessary or beneficial to remove or decrease the concentration of such detrimental materials from the feed stream gas by pre-treatment to decrease or avoid catalyst deactivation. Potentially detrimental species include hydrogen sulfide, hydrogen cyanide, ammonia, and carbonyl sulfides.

The F-T product stream contains hydrocarbons, water and may contain unconverted CO as well as CO2. The feed stream may contain CO2 which survives the reaction and exits in the product stream. In addition, CO2 may be produced in the reactor which is generally undesirable. In specific embodiments herein employing catalysts of this invention, only very low levels or no CO2 is produced in the F-T reactor. Preferably, the amount of CO2 entering the reactor is less than or equal to the amount of CO2 exiting the reactor in the product stream. CO2 levels can be assessed, for example, by measurement of the total mass flow rate of CO2. When this measurement is used, the total mass flow rate of CO2 which leaves the reactor is preferably less than or equal to the amount of CO2 in the feed gas stream. In specific embodiments, F-T methods of this invention can be employed to generate product streams in which the mass flow rate of CO2 out of the reactor is less than 90% of the mass flow rate of CO2 in the feed stream. In specific embodiments, F-T methods of this invention can be employed to generate product streams in which the mass flow rate of CO2 out of the reactor is less than 75% of the mass flow rate of CO2 in the feed stream.

Mass flow rate of gases in the feed gas stream and in the product stream can be measured by any method known in the art. This is one method by which such comparisons can be made, but other methods are known in the art and can be employed to assess feed stream components and product stream components.

Employing catalysts of this invention, CO conversion greater than 20 mole% can be obtained. In preferred embodiments, employing catalysts of this invention CO conversion rates greater than 50% and greater than 75 mole% can be obtained.

The invention further relates to methods of carrying out Fischer-Tropsch synthesis employing one or more catalysts of the present invention. In general, the F-T synthesis can be
carried out in any known reactor type as described in more detail below. In specific embodiments the catalysts of this invention are employed in slurry type catalyst systems. Catalysts of this invention can be employed in a slurry with an appropriate hydrocarbon oil. In specific embodiments, a catalyst of this invention is present in such a slurry from about 1% to about 10% by weight.

In specific embodiments, the invention provides methods for conversion of CO and hydrogen mixtures, particularly those generated by coal, biomass, or waste gasification processes or by the reforming or partial oxidation of natural gas to products containing mixtures of hydrocarbons, particularly products that are liquid hydrocarbon mixtures. In more specific embodiments, the invention provides methods for preparation of clean fuels, such as diesel fuels, which have little or no sulfur or nitrogen contaminants.

Reactor space velocity herein is the rate of flow of feed stream gases normalized for the amount of catalyst at STP. More specifically, it is the volume of gas for a given time and a given amount of catalyst and can be expressed as ml of feed stream gas (e.g., synthesis gas) / min/g catalyst. The catalysts of this invention can be employed for F-T synthesis over a wide range of space velocities, e.g., from 1-50 ml feed stream gas/g catalyst, or in terms of GHSV (gas hourly space velocity again at STP) from 10 to 10,000 h⁻¹. As will be appreciated in the art, the range of reactor space velocities employed in a given catalytic reaction will depend upon the type and size of reactor employed, the feed stream components, the type of catalyst, other operating conditions (e.g., pressure and temperature). One of ordinary skill in the art can select appropriate space velocity for a given catalytic reaction, in a selected reactor and set of operating conditions. It will be appreciated that space velocity for a given catalytic reaction in a given reactor under selected operating conditions can be optimized to achieve improvement in a desired product composition. In general, in the F-T synthesis herein decreasing space velocity results in higher conversion to products, but can also result in higher yields of undesired CO₂ at a fixed temperature.

Reactor Types/Configurations for Use with the Catalysts of the Invention:

There are four preferred reactor types that can be employed with the catalysts of the present invention: 1) Slurry phase or continuously stirred tank reactor (CSTR), 2) fluidized bed, 3) slurry bubble column, and 4) fixed bed reactors. The reactor type selected depends on the catalyst employed, reaction conditions, and products desired. For example, the first three reactor types involve much motion of catalyst particles. Materials which are robust and mechanically strong can be employed in the fluidized bed, CSTR, and slurry bubble column reactors. Less resilient catalysts can be used in these reactors if they are inexpensive enough (e.g., Fe-containing catalysts). However, use of the fixed bed reactor is preferred with these materials.

The choice of reactor type also depends on the efficiency of heat removal. This influences not only the FTS reaction but also the catalyst’s thermal stability. For example, copper and Fe-containing catalysts are particularly subject to deactivation by sintering, so the reduction exothermicity is not adequately removed. Fixed bed reactors are less efficient in heat removal and the other types better suited to this purpose. The same can be said for the FTS reaction.

F-T synthesis can be carried out in fixed bed reactors in which the reactant gas mixture is passed over a bed of solid catalyst. For example, a fixed bed reactor can comprise a plurality of tubes or catalyst containers within a reactor shell. Due to the high exothermicity of the synthesis, all F-T reactor designs require adequate provisions for temperature control to prevent reaction runaway. In fixed bed reactors, excess heat can be carried away by forming steam from water, which is added to the reactor shell surrounding the tubes.

F-T synthesis can be carried out in fluidized bed reactors. Fluidized bed reactors for low-temperature F-T reactors are also called slurry bubble column, slurry bed, slurry phase, or multiphase reactors, and consist of a reactor shell containing a slurry comprising catalyst particles and a hydrocarbon liquid phase. The reactor shell and the slurry are typically cooled employing cooling coils. The feed gas stream is introduced into the slurry. The reactor typically has a feed stream distribution system that introduces the feed stream at the bottom of the slurry, for example as small gas bubbles that rise up through the slurry. The gases of the feed stream diffuse through the liquid phase in the slurry encounter catalyst particles and react. Heavyer hydrocarbons that may be produced are liquid under typical reactor operating temperatures and pressures and are incorporated into the slurry. Lighter gaseous products (at reaction temperature and pressure) and water vapor pass out of the slurry and can be collected as a product stream. Unconverted reactants can be recycled.

Fixed bed reaction may overheat reducing catalyst lifetime by deactivation and/or coke formation. In general, fluidized bed reactors can tolerate higher average operating temperatures than fixed bed reactors without such problems. In a fixed bed reactor, operation must be typically be halted to replace or regenerate catalyst. In a fluidized bed process, catalyst additions and catalyst regenerations can be performed while the reactor is operating in a continuous mode.

Sie and Krishna (Appl. Catalysis A: General 1999, 186, p. 55) give an overview of the development of various F-T reactors and discuss the advantages of slurry bubble reactors over fixed bed reactors.

Operating Temperature Range for Catalysts of the Present Invention:
The preferred operating temperature range of materials of the present invention depends on the composition of materials. In particular, Cobalt-containing materials are more active at a given temperature and are thus more useful at lower temperatures. Cobalt-containing materials are useful at temperatures between 200 and 350°C. The effect of temperature on product selectivity is anticipated to be similar in both cases: α, the chain growth probability in the Anderson-Flory-Schulz (AFS) distribution, decreases with increasing temperature. Thus, decreased production of heavier hydrocarbons, including waxes, is expected as the temperature is increased. In addition, increased aromatic content and chain branching, i.e., more favorable conditions for gasoline production, will occur. Increased CO conversion and increased yield of CO₂, owing to greater activity towards both FTS and water-gas shift tend to occur.

Most generally the invention provides unfinished catalysts of formula I:

\[ A^1 A^2 A^3 B^{1'} B^{2'} B^{3'} O \]

where the subscripts u, v, w, x, y, z are normalized to give \( u+v+w+x+y+z = 4 \) and \( n \) is equal to 6-6, where \( n \) is a number that makes the compound charge neutral and wherein:

- \( A^1 \) is \( \text{Ca}^2^+ \), \( \text{Mg}^2^+ \), \( \text{Sr}^2^+ \), \( \text{Ba}^2^+ \) or mixtures thereof;
- \( A^2 \) is \( \text{Y}^{3^+} \), \( \text{La}^{3^+} \), lanthanide metal 3+ ion, or mixtures thereof;
- \( B^{1'} \) is \( \text{Li}^+ \), \( \text{Na}^+ \), \( \text{K}^+ \), or \( \text{Cs}^+ \);
- \( B^{2'} \) is \( \text{Fe} \), \( \text{Co} \), \( \text{Ni} \), or \( \text{Ru} \) ion or a mixture of these ions;
- \( B^{3'} \) is a Boron, Al, Ga, or In +3 ions or a mixture of these +3 ions.
B is a Cu²⁺ or Zn²⁺ ion or a mixture of these 2⁺ ions; and
wherein:

0.6 ≤ v ≤ 1.0
0.05 ≤ w ≤ 0.25
1.0 ≤ x ≤ 1.99
0.1 ≤ y ≤ 0.9 and
0.05 ≤ z ≤ 1.0;
In additional embodiments:
B1. In each of A1-A14, 0.01 ≤ w ≤ 0.25 and/or 0.01 ≤ z ≤ 1.0; or
B2. In each of A1-A14, 0.1 ≤ w ≤ 0.25 and/or 0.1 ≤ z ≤ 1.0; or
B3. In each of A1-A14, 0.1 ≤ w ≤ 0.25 and/or 0.1 ≤ z ≤ 1.0; or
B4. In each of A1 to A14, 0.1 ≤ w ≤ 0.25 and 0.1 ≤ z ≤ 0.7; or
B5. In each of A1 to A14, w = 0.2 and 0.1 ≤ z ≤ 0.7; or
B6. In each of A1-A14 and B1-B5, A is Sr²⁺;
B7. In each of A1-A14 and B1-B5, A' is La³⁺;
B8. In each of A1-A14 and B1-B5, B is Fe;
B9. In each of A1-A14 and B1-B5, B is Co;
B10. In each of A1-A14 and B1-B5, B is a mixture of Fe and Co;
B11. In each of A1-A14 and B1-B5, B' is Ga or Al;
B12. In each of A1-A14 and B1-B5, where A" is present A" is K⁺;
B13. In each of A1-A14 and B1-B5, where B" is present B" is Cu²⁺.
In specific embodiments, catalysts of formula 1 contain 4, 5 or 6 different metal ions.
In other specific embodiments, catalysts of formula 1 contain 4, 5 or 6 different metal ions.
The invention provides unfinished catalysts of formula IV wherein:

A = K+, Fe, or Co ions or a mixture of these ions; B' is Al or Ga +3 ions or a mixture of these +3 ions; and B" is a Cu+ ion. These embodiments in which the subscripts u, v, w, x, y and z can take values as listed above in A1 to A14.

In other specific embodiments, the catalysts of formula I are obtained, the material may or may not exhibit diffraction patterns of phases of the above crystal structures. Particularly useful catalysts are prepared by reduction of mixed metal oxides containing Cu ions in combination with Fe ions and in combination with Ga or Al ions and Sr and La ions which are prepared with perovskite-type stoichiometry prior to reduction. Useful catalysts are also prepared by reduction of mixed metal oxides containing cobalt ions in combination with Ga ions in combination with Sr or La ions and which are prepared with perovskite-type stoichiometry prior to reduction. Additional useful catalysts of the invention are prepared by reduction of Sr/La ion-containing mixed metal oxides which contain one or more of Fe, Co, Cu, Mn, Ni or Ru ions and one or more of Co, Al, Ga or In ions which preferably exhibit a perovskite-type stoichiometry. In specific embodiments, finished catalysts of this invention include, among others, those having formula IV wherein:

A is Sr2+; A' is La3+; A" = K+, B is Fe, or Co ions or a mixture thereof; B' is Al+3; and B" is a Cu+2 ion. In these embodiments, the subscripts u, v, w, x, y and z can take values as listed above in A1 to A14.

In other specific embodiments, unfinished catalysts of this invention include, among others, those having formula I wherein:

A is Sr2+; A' is La3+; A" = K+, B is Fe, or Co ions or a mixture thereof; B' is Al+3; and B" is a Cu+2 ion. In these embodiments, the subscripts u, v, w, x, y and z can take values as listed above in A1 to A14.

In other specific embodiments, the unfinished catalysts herein have formula II:

\[ S_\text{r} \text{La}_x \text{Fe}_y \text{Al}_z \text{O}_{6.0} \]

wherein: u + v = 2; 1.5 ≤ x ≤ 2; 0 ≤ y ≤ 0.9; and 0 ≤ z ≤ 0.8.

In specific embodiments of formula II:

0.30 ≤ u ≤ 0.55; 0.7 ≤ v ≤ 1.00; 0.01 ≤ w ≤ 0.25; 1.7 ≤ x ≤ 1.9; 0.15 ≤ y ≤ 0.85; and 0.15 ≤ z ≤ 0.7.

In other specific embodiments, the unfinished catalysts herein have formula III:

\[ S_\text{r} \text{La}_x \text{Fe}_y \text{Al}_z \text{O}_{6.0} \]

wherein: u + v = 2; 1.5 ≤ x ≤ 2; 0.10 ≤ z ≤ 0.85; and 0.02 ≤ z ≤ 0.8.

In specific embodiments of formula III:

z is 0; z is 0 and B is Co; or 0.15 ≤ z ≤ 0.8 and B is Fe; 0.10 ≤ z ≤ 0.8; and B is Fe and 1.5 ≤ x ≤ 2.

The invention also provides unfinished catalysts of formula IV:

\[ A_n \text{A'}_m \text{B}_p \text{B''}_q \text{O}_{6+n} \]

wherein:

A is Ca2+, Mg2+, Sr2+, Ba2+ or mixtures thereof; A' is Y3+, La3+, any lanthanide metal 3+ ion, or mixtures thereof; B is Fe, Mn, Ni, or Ru ion or a mixture of these ions; B' is a Boron, Al, Ga, or In ion or a mixture of these +3 ions; B" is Cu+2 or Zn+2; u, v, x, y and z are numbers wherein; 0.25 ≤ u ≤ 1.0; and 0.25 ≤ z ≤ 1.0.

δ is a number that renders the metal oxide charge neutral.

In specific embodiments of formula IV: 0.2 ≤ x ≤ 1.8; 0.2 ≤ y ≤ 1.0; and 0.2 ≤ z ≤ 1.0.

In specific embodiments of formula IV, B is an ion of Fe or Co or a mixture of Fe and Co ions. In other embodiments, B is an ion or mixture of ions other than those of Fe or Co. In more specific embodiments, the unfinished catalysts of this invention include, among others, those having formula IV wherein:

A is Sr2+; A' is La3+; A" = K+, B is an Fe or Co ion; or a mixture thereof; B' is Al+3; and B" is a Cu+2 ion. In these embodiments, the subscripts u, v, w, x, y and z can take values as listed above in A1 to A14.
represents about 50% of more by weight of the metal oxide. Catalysts of this invention include metal oxides comprising a metal oxide phase of formulas I-IV above wherein the specified metal oxide phase represents about 75% of more by weight of the metal oxide. Catalysts of this invention include metal oxides comprising a metal oxide phase of formulas I-IV above wherein the specified metal oxide phase represents 85% of more by weight of the metal oxide. Catalysts of this invention include metal oxides comprising a metal oxide phase of formulas I-IV above wherein the specified metal oxide phase represents 95% of more by weight of the metal oxide.

In specific embodiments, the unfinished F-T catalyst does not contain Ag. In other specific embodiments, the unfinished F-T catalyst is not a mixture of lanthanum oxide and barium oxide containing cobalt and ruthenium. In additional embodiments, the unfinished F-T catalyst is not one or more Group 8, 9 or 10 metals (IUPAC Periodic Table) impregnated in alumina. In yet other specific embodiments, the unfinished F-T catalyst is not supported on Ti-doped alumina. In another specific embodiment, the unfinished F-T catalyst is not a non-promoted cobalt catalyst. In yet another specific embodiment, the unfinished F-T catalyst does not contain palladium.

Catalyst formulations optionally include in addition to one or more catalysts of this invention other catalysts which are known in the art to exhibit catalytic activity for Fischer-Tropsch synthesis. The invention provides catalyst compositions which consist essentially of one or more of the catalysts of formulas I-IV wherein the variables of the formulas can be selected as described above. The invention provides catalyst compositions consisting of one or more of the catalysts of formulas I-IV wherein the variables of the formulas can be selected as described above. Catalyst formulations of this invention also include those that comprise one catalyst of any of formulas I, II, III or IV.

Catalysts of this invention can be employed in catalytic reactions in a variety of forms and configurations known in the art. For example, catalysts can be provided as a coating on or impregnated in support materials. Any known catalyst support material that does not detrimentally affect the desired catalytic reaction can be used. Preferred support materials do not themselves function as a catalyst under the conditions in which they will be employed in this invention to generate undesirably products. Support materials may, however, facilitate or enhance the activity or selectivity of the active catalyst of the invention. Support materials can include, among others alumina; silica; silica-alumina; ceria; titania, thoria, boria, zirconia, kieselguhr; magnesia or a mesoporous material, for example mesoporous alumina or silica. Supported or impregnated catalysts of this invention can generally comprise from about 1% to about 95% by weight of active catalyst. More typically supported catalysts of this invention comprise from about 5% to 35% by weight of active catalyst. More typically impregnated catalysts of this invention comprise from about 5% to about 35% by weight of active catalyst.

In a specific embodiment, impregnated supported catalysts can be formed by incipient wetness impregnation in which the support is wetted with a solution containing a selected mixture of metal ion precursors (e.g., metal nitrates, metal sulfates, metal acetates, metal acetylacetonates, metal lactates, or mixtures thereof). The mixture of metal ion precursors is selected to achieve the desired metal composition and stoichiometry of the active catalyst.

Reduction of Mixed Metal Oxides:

Unfinished catalysts for F-T synthesis must be reduced prior to or during use in the reaction to activate the catalyst, i.e., render it into its usefully active form. This reduction step consists of exposure of the unfinished catalyst to a reducing gas. This reducing gas is generally comprised of hydrogen or a mixture of CO and hydrogen (synagas) in such concentration as to impart maximal activity, with minimal sintering to the catalyst. Conditions employed in this activation step depend on the catalyst being employed. For example, iron containing catalysts can be conveniently reduced in situ by exposure to reaction feed (synagas with H₂:CO of 0.3 to 3 or greater) or to pure or diluted hydrogen (diluted with a non-reactive gas, e.g., inert gas or nitrogen). Useful levels of hydrogen are from 5%-60% at 150 to 300° C. at 150-500 psig and space velocity of 5-30 ml/min/g catalyst. Useful conditions for activation in reaction feed are a temperature of 170-350° C. with an H₂:CO ratio of 0.3 to 3 or greater and pressure of 150-500 psig. Exposure to reduction conditions may range from 2 to 72 hours. Preferred conditions for reduction of catalysts, particularly Fe-containing catalysts, of the subject invention are exposure to 100% hydrogen at 150 psig and 250° C. for 24-72 hours.

 Cobalt catalysts are preferably reduced ex situ at temperatures between 250 and 600° C. in pure hydrogen or at hydrogen concentrations between 25 and 100% and at atmospheric pressure or pressures between 1 and 30 atmospheres. Preferred reduction conditions are exposure to 100% hydrogen gas at 350° C. for >12 hours. The catalyst must then be transferred to the FTS reactor with exclusion of air. An important consideration is the rate of temperature increase during catalyst reduction: A temperature ramp rate of 3° C./min or less is preferred to prevent the extremely exothermic reduction process from causing sintering of catalyst metals.

If it is desired to know the conditions for reduction prior to use, thermogravimetric analysis can be used to determine the weight loss of a catalyst sample upon exposure to reducing gas. The material in the oxidized form is weighed, heated in the presence of a reducing gas, and then reweighed following reduction. The ratio of the weight loss to initial weight is a measure of reducibility. The optimal reduction temperature can be determined from the observed weight loss as a function of temperature.

Catalytic metals used in the F-T synthesis are usually active for hydrocarbon synthesis in the zero-valent metallic state. Reduced catalytic metals are highly susceptible to oxidation by any number of oxidizing agents, particularly by molecular oxygen in air. Oxidation of the reduced catalytic metals to an oxidized state decreases the catalyst activity. It is beneficial to protect reduced catalyst from any oxidation, such as by oxygen from air. Because of the sensitivity of activated catalysts to oxidation in situ reduction/activation of catalysts is preferred. However, methods are known in the art for catalysts reduction/activation external to the reactor. For example, reduced catalysts can be embodied in a coating material, for example a wax or oil, to provide a barrier to oxidation.

Granule Size for Catalysts of the Present Invention:

Catalyst particle size can significantly affect performance of catalysts of the present invention. Particle size partially determines catalyst surface area and also influences mass transport in pores. Generally, smaller particle size favors higher performance of the catalyst because of the higher surface area and reduced mass transport resistance. However, in F-T slurry reactors, a lower limit on particle size is necessary, as smaller particles tend to clog filters designed to separate catalyst from the slurry medium. Catalyst particle size of between less than 1 μm and up to 1000 μm may be used, but
the preferred particle size range for catalysts of the present invention is between 20 and 150 µm.

When a group of metals or metal ions is disclosed herein, it is understood that all individual members of that group and all subgroups of the group members, are disclosed separately. In general, when a Markush group or other grouping is used herein, all individual members of the group and all combinations and subcombinations possible of the group are intended to be individually included in the disclosure. Additionally, unless otherwise specified, all isotopic variants of compounds disclosed herein are intended to be encompassed by the disclosure. Every formulation or combination of components described or exemplified herein can be used to practice the invention, unless otherwise stated.

Whenever a range is given in the specification, for example, a temperature range, a time range, or a composition or concentration range, the range given is intended to be inclusive of the endpoints given, and all intermediate ranges and subranges, as well as all individual values included in the ranges given are intended to be included in the disclosure. The specification contains specific examples for the preparation of mixed metal compounds. Those of ordinary skill in the art will appreciate that other methods for the preparation of these materials are known in the art. As indicated herein the method of preparation of the catalyst may affect catalyst performance.

It is understood in the art that starting material for the preparation of the mixed metal oxide species of this invention may contain minor impurities which contain metals or metal ions in addition to those listed in the formulas herein. It will be appreciated that such minor impurities are encompassed within the formulas disclosed herein to the extent that the impurities do not substantially detrimentally affect the properties of the materials herein for uses described herein.

All patents and publications mentioned in the specification and examples are indicative of the levels of skill of those skilled in the art to which the invention pertains. References cited herein are incorporated by reference herein in their entirety to indicate the state of the art as of their filing date and it is intended that this information can be employed herein, if needed, to exclude specific embodiments that are in the prior art. For example, when a compound is claimed, it should be understood that compounds known and available in the art prior to Applicant's invention, including compounds for which an enabling disclosure is provided in the references cited herein, are not intended to be included in the composition of matter claims herein.

As used herein, “comprising” is synonymous with “including,” “containing,” or “characterized by;” and is inclusive or open-ended and does not exclude additional, unrecited elements or method steps. As used herein, “consisting of” excludes any element, step, or ingredient not specified in the claim element. As used herein, “consisting essentially of” does not exclude materials or steps that do not materially affect the basic and novel characteristics of the claim. In each instance herein any of the terms “comprising”, “consisting essentially of” and “consisting of” may be replaced with either of the other two terms. The invention illustratively described herein suitably may be practiced in the absence of any element or elements, limitation or limitations which is not specifically disclosed herein.

One of ordinary skill in the art will appreciate that starting materials, reagents, solid substrates, synthetic methods, purification methods, and analytical methods other than those specifically exemplified can be employed in the practice of the invention without resort to undue experimentation. All art-known functional equivalents, of any such materials and methods are intended to be included in this invention. The terms and expressions which have been employed are used as terms of description and not of limitation, and there is no intention that in the use of such terms and expressions of excluding any equivalents of the features shown and described or portions thereof, but it is recognized that various modifications are possible within the scope of the invention claimed. Thus, it should be understood that although the present invention has been specifically disclosed by preferred embodiments and optional features, modification and variation of the concepts herein disclosed may be resorted to by those skilled in the art, and that such modifications and variations are considered to be within the scope of this invention as defined by the appended claims.

All references cited herein are hereby incorporated by reference to the extent that there is no inconsistency with the disclosure of this specification. Some references provided herein are incorporated by reference to provide details concerning sources of starting materials, additional starting materials, additional reagents, additional methods of synthesis, additional methods of analysis and additional uses of the invention.

THE EXAMPLES

Example 1

Preparation of Sr1.4La0.6Fe1.6Ga0.4Cu0.6O5.6

Using the ceramic method: 23.34 g of strontium carbonate, 11.98 g of lanthanum oxide, 9.79 g of iron (III) oxide, 4.96 g of gallium oxide, and 5.85 g of copper (II) oxide were combined, added to a plastic bottle along with an isopropanol carrier and zirconia grinding media and ball milled for about 2 days. The mixture was calcined at 1000°C for 8 hours. The resulting powder (53.8 g) was ground and sieved to 100 mesh.

Powder x-ray diffraction showed that a single, perovskite-type phase was present. In preparations by the ceramic method, the detection limit for an additional phase is of the order of 2-3% of the first or major phase present. The surface area of the material was determined using physisorption of nitrogen and the Brunauer, Emmett, and Teller equation for the isotherm and found to be 0.7 m²/g.

Assessment of Catalytic Activity

The activity of the catalyst Sr1.4La0.6Fe1.6Ga0.4Cu0.6O5.6 was measured in a slurry phase reactor in which catalyst is suspended in a high boiling hydrocarbon oil (Durasyn 164, BP). The reactor consisted of a 1 L, 316 stainless steel reactor incorporating a CF flange and copper seal. The reactor employed a small paddle stirrer with a packed gland stirring mechanism. A catalyst weight loading (100x (weight catalyst)/(weight slurry+weight catalyst)) of 5% was employed. The catalyst was reduced prior to reaction by heating at 280°C under hydrogen (150 psig) delivered at a space velocity of 24 mL/min·g·cat. Immediately following catalyst reduction, Fischer-Tropsch synthesis was carried out using the catalyst as follows. The reactor was cooled to 250°C and a gas mixture composed of 50% by volume carbon monoxide and 50% by volume hydrogen was introduced into the reactor at a pressure of 250 psig and a space velocity of 18 mL/min·g·cat. The data obtained on six samples of the same catalyst are presented in Table 1. These data show very little formation of carbon dioxide.
Preparation of \(\text{Sr}_{1.52}\La_{0.69}\Fe_{1.68}\Al_{0.27}\Cu_{0.14}\Os_{0.86}\):  

Using the ceramic method: 28.47 g of strontium carbonate, 13.47 g of lanthanum oxide, 11.00 g of iron (III) oxide, 2.81 g of aluminum oxide, and 6.57 g of copper (II) oxide were combined and added to a 25 mL screw cap plastic bottle along with an isopropanol carrier and 5 cylindrical toughened-zirconia grinding media. The solvent was evaporated from this mixture, which was then heated to 90°C for 8 hours. The resulting powder was placed into an alumina crucible, brought to 1000°C at 3°C/min and calcined at this temperature for 8 hours. The calcined material (53.8 g) was crushed and sieved to 100 mesh through a wire screen.

Example 3

Co-precipitated \(\text{Sr}_{0.31}\La_{0.78}\K_{0.08}\Fe_{1.88}\Al_{0.81}\Cu_{0.14}\Os_{0.70}\):  

A solution was prepared by dissolving 37.91 g of \(\text{Sr(NO}_3\text{)}_2\) and 32.813 g of \(\text{La(NO}_3\text{)}_3\cdot5\text{H}_2\text{O}\) in 250 mL of water. A 45% KOH solution (52.9 mL) was added dropwise to this solution with stirring. The mixture was allowed to stir overnight. A separate solution was prepared by dissolving 51.692 g of \(\text{Fe(NO}_3\text{)}_3\cdot9\text{H}_2\text{O}\), 19.197 g of \(\text{Al(NO}_3\text{)}_3\cdot2\cdot5\text{H}_2\text{O}\), and 12.866 g of \(\text{Cu(NO}_3\text{)}_2\cdot2\cdot5\text{H}_2\text{O}\) in 250 mL of water. A 45% KOH (55 mL) solution was added dropwise and the resulting mixture stirred overnight. The two precipitates were separately washed with water and suction filtered. The precipitated solids were then combined, 850 mL of water was added and the mixture stirred for about 75 minutes. The mixture was filtered and the combined precipitates were air dried overnight. The dried solids were further dried by exposure to a heat lamp. The dried solid was ground with a mortar and pestle to less than 150 μm and then calcined at 450°C for 8 hours. The resulting powder was then sieved to ≤150 μm. The yield was 35.6 g. Powder x-ray diffractionometry gave a pattern that was characteristic of non-crystalline or small crystalline size solids. Energy dispersive x-ray spectroscopy (EDX) gave the following formula for the material:  

\[
\text{Sr}_{0.31}\La_{0.78}\K_{0.08}\Fe_{1.88}\Al_{0.81}\Cu_{0.14}\Os_{0.70}
\]

Nitrogen physisorption measurements and the Brunauer-Emmett-Teller (BET) model for multilayer adsorption gave a specific surface area of 39.86 m²/g. Nitrogen physisorption isotherms, along with the Barrett-Joyner-Halenda (BJH) model, were used to determine the pore size distribution (PSD) and total pore volume. The PSD was found to give maxima at 55 and 150 Å. The total pore volume obtained was 0.17 cm³/g.

Preparation of \(\text{Sr}_{0.98}\La_{0.02}\Fe_{1.78}\Al_{0.20}\Os_{0.48}\):  

A solution was prepared by dissolving 6.09 g of \(\text{Sr(NO}_3\text{)}_2\), 31.17 g of \(\text{La(NO}_3\text{)}_3\cdot5\text{H}_2\text{O}\), 11.09 g of \(\text{Cu(NO}_3\text{)}_2\cdot2\cdot5\text{H}_2\text{O}\), 53.31 g of \(\text{Fe(NO}_3\text{)}_3\cdot9\text{H}_2\text{O}\), 0.14 g of KOH, and 5.51 g of \(\text{Al(NO}_3\text{)}_3\cdot9\text{H}_2\text{O}\) in 300 mL of water along with 61.05 g of glycine and 16.27 g of \(\text{NH}_4\text{NO}_3\). This solution was placed in a 4 L stainless steel beaker and a funnel shrouded at the mouth by a wire screen placed into the beaker. Air was delivered to the mixture via the funnel neck using an air pump. The beaker was heated using a hot plate and the solvent driven off, resulting in a thickened mixture which eventually ignited, producing flames, an ash, and a fine dust. The ash and any powdered remnant of it were attrition ground for 16 hours at 400 rpm using a planetary attrition mill. The resulting powder was sieved through a 100 mesh screen.

Example 5

Preparation of \(\text{Sr}_{0.31}\La_{0.78}\K_{0.08}\Fe_{1.88}\Al_{0.81}\Cu_{0.14}\Os_{0.70}\):  

A solution containing 1.52 g of \(\text{Sr(NO}_3\text{)}_2\), 7.80 g of \(\text{La(NO}_3\text{)}_3\cdot5\text{H}_2\text{O}\), 2.78 g of \(\text{Cu(NO}_3\text{)}_2\cdot2\cdot5\text{H}_2\text{O}\), 13.34 g of \(\text{Fe(NO}_3\text{)}_3\cdot9\text{H}_2\text{O}\), 0.04 g of KOH, and 1.38 g of \(\text{Al(NO}_3\text{)}_3\cdot9\text{H}_2\text{O}\) in 30 mL water was prepared. Alumina powder (50 g) was added to this solution, with thorough mixing. The solvent was removed from the resulting slurry by rotary evaporation for 30 minutes, followed by application of vacuum and heating to 85°C for 2 hours until the solid was dry. The powder was placed in an alumina crucible and dried at 100°C for 5 hours followed by calcinations at 650°C for 8 hours. The calcined solid was then loaded a second time by the same procedure as above, with the exception that the solid exposed to fresh solution was dried at 120°C for 2 hours. The final product, after calcinations at 650°C for 8 hours again, was sieved to ≤150 μm.

Example 6

Preparation of \(\text{Sr}_{0.52}\La_{0.69}\Co_{1.87}\Al_{0.20}\Os_{0.92}\):  

A solution was prepared by dissolving 37.419 g of \(\text{Sr(NO}_3\text{)}_2\), 32.816 g of \(\text{La(NO}_3\text{)}_3\cdot5\text{H}_2\text{O}\) in 250 mL of water. A 45% KOH solution (53.0 mL) was added dropwise to this solution with stirring. The mixture was allowed to stir overnight. A separate solution was prepared by dissolving 58.81 g of \(\text{Co(NO}_3\text{)}_2\cdot6\text{H}_2\text{O}\) and 18.951 g of \(\text{Al(NO}_3\text{)}_3\cdot9\text{H}_2\text{O}\) in 250 mL of water. A 45% KOH (55 mL) solution was added dropwise until a pH of 7.7 was obtained and the resulting mixture stirred overnight. The two precipitates were separately washed with water and suction filtered. The precipitated solids were then combined, 850 mL of water was added and the mixture stirred for about 75 minutes. The mixture was filtered, washed with water, and the combined precipitates were air dried overnight. These solids were further dried by heating at 115°C for 4 hours. The dried solid was ground with a mortar and pestle to less than 150 μm and then calcined at 450°C for 8 hours. The resulting powder was then sieved to ≤150 μm. The Powder x-ray diffractometry gave a pattern that was characteristic of non-crystalline or small crystalline size solids. Energy dispersive x-ray spectroscopy (EDX) gave the following formula for the material:
The pore size distribution (PSD) and total pore volume were determined using the Barrett-Joyner-Halenda (BJH) model. Nitrogen physisorption measurements and the Brunauer-Emmett-Teller (BET) model were used to determine the pore size distribution (PSD) and total pore volume. The PSD was found to give a maxima at 43 Å. The total pore volume obtained was 0.186 cm³/g.

### Example 7

Preparation of Co-Precipitated $X_{40-11}$

A solution was prepared by dissolving $11.375$ g of Sr(NO₃)₂ and $9.844$ g of La(NO₃)₃·6H₂O in $77$ mL of water. A $45\%$ KOH solution ($16$ mL) was added dropwise to this solution with stirring. The mixture was allowed to stir overnight. A separate solution was prepared by dissolving $15.51$ g of Fe(NO₃)₃·9H₂O, $5.759$ g of Al(NO₃)₃·9H₂O, and $5.355$ g of Cu(NO₃)₂·2.5H₂O in $77$ mL of water. A $45\%$ KOH solution ($16.5$ mL) was added dropwise until a pH of $7.7$ was obtained and the resulting mixture stirred overnight. The precipitated solids were then combined, $220$ mL of water was added and the mixture stirred for about $75$ minutes. The mixture was filtered and the combined precipitates were washed with water and suction filtered. The precipitated solids were then combined, washed, and dried at $450\degree C$. The yield was $81.74$ g. Powder x-ray diffractometry gave a pattern that was characteristic of non-crystalline or small crystallite size solids. Energy dispersive x-ray spectroscopy (EDX) gave the following formula for the material:

$$S_{0.63}A_{0.58}F_{0.55}A_{0.54}O_{0.50}.$$  

### Example 8

Preparation of Co-Precipitated $X_{40-08}$

A solution was prepared by dissolving $11.508$ g of Fe(NO₃)₃·9H₂O, $5.762$ g of Al(NO₃)₃·9H₂O, and $5.358$ g of Cu(NO₃)₂·2.5H₂O in $77$ mL of water. A $45\%$ KOH solution ($16.5$ mL) was added dropwise until a pH of $7.7$ was obtained and the resulting mixture stirred overnight. The two precipitates were separately washed with water and suction filtered. The precipitated solids were then combined, $220$ mL of water was added and the mixture stirred for about $75$ minutes. The mixture was filtered and the combined precipitates were washed with water and suction filtered. The dried solid was then forced through a $600$ mesh sieve and then calcined at $450\degree C$. The yield was $10.46$ g. Powder x-ray diffractometry gave a pattern that was characteristic of non-crystalline or small crystallite size solids. Energy dispersive x-ray spectroscopy (EDX) gave the following formula for the material:

$$S_{0.63}A_{0.58}F_{0.55}A_{0.54}O_{0.50}.$$  

### Example 9

Preparation of Coprecipitated $X_{40-24}$

A solution was prepared by dissolving $75.819$ g of Sr(NO₃)₂ and $66.850$ g of La(NO₃)₃·5.69H₂O in $500$ mL of water. A $45\%$ KOH solution ($106$ mL) was added dropwise to this solution with stirring. The mixture was allowed to stir overnight. A separate solution was prepared by dissolving $103.384$ g of Fe(NO₃)₃·9H₂O, $38.399$ g of Al(NO₃)₃·9H₂O, and $35.712$ g of Cu(NO₃)₂·2.5H₂O in $77$ mL of water. A $45\%$ KOH ($110$ mL) solution was added dropwise until a pH of $7.5$ was obtained and the resulting mixture stirred overnight. The precipitates were separated and washed with water and suction filtered. The precipitated solids were then combined, washed, and dried at $1700\degree C$. The yield was $9.16$ g. Powder x-ray diffractometry gave a pattern that was characteristic of non-crystalline or small crystallite size solids. Energy dispersive x-ray spectroscopy (EDX) gave the following formula for the material:

$$S_{0.63}A_{0.58}F_{0.55}A_{0.54}O_{0.50}.$$  

### Example 10

Assessment of FTS Catalytic Activity of $X_{40-08}$, $X_{40-11}$, and $X_{40-13}$:

The activities of the catalysts $X_{40-08}$, $X_{40-11}$, and $X_{40-13}$ were measured in a slurry phase reactor in which catalyst is suspended in a high boiling hydrocarbon oil (Durasyn 164, BP). The reactor consisted of a stainless steel reaction vessel with a small paddle stirrer and a packed bed of catalyst. The catalyst was suspended in a high boiling hydrocarbon oil (Durasyn 164, BP). The reactor consisted of a stainless steel reaction vessel with a small paddle stirrer and a packed bed of catalyst. The catalyst was suspended in a high boiling hydrocarbon oil (Durasyn 164, BP). The reactor consisted of a stainless steel reaction vessel with a small paddle stirrer and a packed bed of catalyst.
the reactor at a pressure of 250 psig and a flow rate of 18 mL/min-g catalyst. The data obtained are presented in Table 2. These data show less formation of carbon dioxide than a baseline precipitated iron catalyst, even when conversion is comparable.

Table 2 also provides a comparison of Sr1-x39-08Al2O3 catalyst activity as a function of its preparation (X40-08 (coprecipitated) or X40-08A (glycine-nitrate combustion) or whether or not the catalyst is supported (X40-08B)). In general, coprecipitation gives better catalyst characteristics for F-T synthesis, than the glycine-nitrate method.

An average alpha of 0.78 was determined for the X40-13 catalyst for carbon numbers between 6 and 24. In comparison, the average alpha determined for the baseline precipitated iron catalyst above was 0.70 and the average alpha determined for the baseline alumina supported cobalt catalyst was 0.75.

Assessment of FTS Catalytic Activity of X40-24 and Y4201:

The activities of the catalysts X40-24 and Y4201 were measured as above in a slurry phase reactor in which catalyst is suspended in a high boiling hydrocarbon oil (Durasyn 164, BP). The reactor consisted of a 300 mL stainless steel reaction bomb. The reactor employed a small paddle stirrer with a packed gland stirring mechanism. A catalyst weight loading (100x (weight catalyst)/(weight slurry+weight catalyst)) of 0.70 was used.

The method of claim 1 wherein the reactor is a fixed bed reactor.

We claim:
1. A process for the production of hydrocarbons comprising the steps:
   (a) introducing a feed gas stream comprising hydrogen, carbon monoxide, and carbon dioxide into a Fischer Tropsch reactor;
   (b) reacting said feed gas in the reactor employing a mixed metal oxide catalyst where the reactor is operated at a pressure from 100 psig to 1200 psig and a temperature between 175°C to 350°C wherein the CO conversion is greater than 20 mole %; and
   (c) collecting product from said reactor where the product comprises hydrocarbon and water wherein the total mass flow rate of CO2 out of the reactor is less than or equal to the amount of CO2 in the feed gas stream wherein the mixed metal oxide catalyst is a catalyst having the formula:

\[ \text{Sr}^{1-x} \text{Al}_{2} \text{O}_{3} \]

wherein \( u + v + w + x + y + z = \text{a whole number and} n \) is a number that makes the compound charge neutral;

\[ A^{n-}, A'^{n+}, B^{m+}, B'^{m+}, O_2^- \]

wherein the reactor is a fixed bed reactor and the catalyst is provided in a slurry at a concentration ranging from 1 wt % to about 10 wt %.

2. The method of claim 1 wherein the reactor space velocity ranges from 1-50 mL/g catalyst.

3. The method of claim 1 wherein the reactor space velocity is greater than 50%.

4. The method of claim 1 wherein the reactor space velocity ranges from 1-50 mL/g catalyst.

5. The method of claim 1 wherein the alpha value of the hydrocarbon products formed is greater than or equal to 0.65.

6. The method of claim 1 wherein the alpha value of the hydrocarbon products formed is greater than 0.75.

7. The method of claim 1 wherein the reactor is supported with a carrier.

8. The method of claim 1 wherein the reactor is a supported catalyst.

9. The method of claim 1 wherein the CO conversion is greater than 50%.
10. The method of claim 1 wherein the catalyst particle size is between 20 \mu m and 150 \mu m.

11. The method of claim 1 wherein in the catalyst B=Fe, or Co ions or a mixture of these ions.

12. The method of claim 1 wherein in the catalyst z is greater than zero and B" is Cu\textsuperscript{2+}.

13. The method of claim 1 wherein in the catalyst is prepared by coprecipitation.

14. The method of claim 1 wherein the catalyst has the formula:
\[ S_{u}La_{v}K_{w}Fe_{x}Al_{y}Cu_{z}O_{n+\delta} \]
wherein: \( 0.20 \leq u \leq 0.60; \quad 0.60 \leq v \leq 1.00; \quad 0.01 \leq w \leq 0.30; \quad 1.5 \leq x \leq 2; \quad 0.10 \leq y \leq 0.9 \) and \( 0.1 \leq z \leq 0.8 \).

15. The method of claim 1 wherein the catalyst has the formula:
\[ S_{u}La_{v}B_{w}Al_{x}Cu_{y}O_{n+\delta} \]
wherein: \( u+v+w+x+y+z=a \) whole number and \( n \) is a number that makes the compound charge neutral; \( A=Ca^{2+},Mg^{2+},Si^{4+},Ba^{2+} \) or mixtures thereof; \( A'=Y^{3+},La^{3+} \), any lanthanide metal \( 3+ \) ion, or mixtures thereof; \( A''=Li^{+},Na^{+},K^{+}, \) or Cs\textsuperscript{+}; \( B=Fe,Co,Ni, \) or Ru ion or a mixture of these ions; \( B' \) is a Boron, Al, Ga, or In \( +3 \) ions or a mixture of these \( +3 \) ions; \( 0.15 \leq u \leq 0.60; \quad 0.50 \leq v \leq 1.00; \quad 1.5 \leq x \leq 3; \quad 0.10 \leq y \leq 0.9 \) and \( 0.05 \leq z \leq 0.8 \).

16. The method of claim 1 wherein the catalyst is
\[ Sr_{0.51}La_{0.73}K_{0.20}Fe_{1.72}Al_{0.63}Cu_{0.65}O_{0.22} \]
17. The method of claim 15 wherein the catalyst is prepared by coprecipitation.

18. The method of claim 1 wherein the catalyst is selected from the group consisting of
\[ Sr_{u}La_{v}Fe_{w}Al_{x}Cu_{y}O_{n+\delta} \]
\[ Sr_{0.51}La_{0.73}K_{0.20}Fe_{1.72}Al_{0.63}Cu_{0.65}O_{0.22} \]
\[ Sr_{0.31}La_{0.78}K_{0.08}Fe_{1.88}Al_{0.81}Cu_{0.14}O_{0.70} \]
\[ Sr_{0.15}La_{0.68}Co_{0.27}Al_{0.14}Cu_{0.14}O_{0.70} \]
\[ Sr_{0.30}La_{0.85}Fe_{1.58}Al_{0.01}Cu_{0.01}O_{0.50} \]
\[ Sr_{0.30}La_{0.85}Fe_{1.58}Al_{0.01}Cu_{0.01}O_{0.50} \]
\[ Sr_{0.30}La_{0.85}Fe_{1.58}Al_{0.01}Cu_{0.01}O_{0.50} \]
\[ Sr_{0.30}La_{0.85}Fe_{1.58}Al_{0.01}Cu_{0.01}O_{0.50} \]
\[ Sr_{0.30}La_{0.85}Fe_{1.58}Al_{0.01}Cu_{0.01}O_{0.50} \]
\[ Sr_{0.30}La_{0.85}Fe_{1.58}Al_{0.01}Cu_{0.01}O_{0.50} \]
\[ Sr_{0.30}La_{0.85}Fe_{1.58}Al_{0.01}Cu_{0.01}O_{0.50} \]

19. The method of claim 18 wherein the catalyst is prepared by coprecipitation.

20. A method for reductive oligomerization of carbon monoxide (CO) in the presence of molecular hydrogen (H\textsubscript{2}) which comprises the step of contacting a feed stream comprising CO and H\textsubscript{2} with an activated reduced catalyst which is formed by reduction of an oxygen-deficient metal oxide having the formula:
\[ A_{u}A'_{v}A''_{w}B_{x}B'_{y}B''_{z}O_{n} \]
wherein \( u+v+w+x+y+z=a \) whole number and \( n \) is a number that makes the compound charge neutral; \( A=Ca^{2+},Mg^{2+},Sr^{2+},Ba^{2+} \) or mixtures thereof; \( A'=Y^{3+},La^{3+} \), any lanthanide metal \( 3+ \) ion, or mixtures thereof; \( A''=Li^{+},Na^{+},K^{+}, \) or Cs\textsuperscript{+}; \( B=Fe,Co,Ni, \) or Ru ion or a mixture of these ions; \( B' \) is a Boron, Al, Ga, or In \( +3 \) ions or a mixture of these \( +3 \) ions; \( B'' \) is a Cu\textsuperscript{2+} or Zn\textsuperscript{2+} ion or a mixture of these \( 2+ \) ions; \( 0.01 \leq u \leq 1.99; \quad 0.01 \leq v \leq 1.99; \quad 0.0 \leq w \leq 0.1; \quad 0.01 \leq x \leq 3.0; \quad 0.01 \leq y \leq 1.99 \) and \( 0.0 \leq z \leq 1.0 \).

21. The method of claim 20 wherein the product stream contains hydrocarbons the majority of which have 5 or more carbon atoms.

22. The method of claim 20 which is conducted at a temperature less than about 300\textdegree C.

23. The method of claim 1 further comprising the step of activating the mixed metal oxide catalyst by reduction prior to reacting the feed gas with the catalyst.
