The goal of the Information Presentation Directed Research Project (DRP) is to address design questions related to the presentation of information including 1) EVA Operations, 2) Fault Management, and 4) Human Performance Modeling. This DRP is a collaborative effort between researchers at Johnson Space Center and Ames Research Center.

### DISPLAYS – Visual displays

#### FY08 Studies

**Label Alignment**

Three studies investigated the effects of label alignment in small and large data groupings: 4, 8, and 16 label/value pairs, as well as high fidelity displays. The task was to find a value that corresponded to a target label.

- For large data groupings, such as the 16-label group, data-alignment is faster than left-alignment.
- In high fidelity displays, there was no difference in search times between left and data-aligned labels.

**Label Orientation**

The purpose of the study was to investigate the effects of label orientation.

Follow-up on alignment studies from FY08, further investigating left-aligned versus data-aligned labels for performance differences. The experimental task will be varied, and eye tracking will be used to gather higher precision data.

- Investigate methods of distinguishing between labels and values, such as colors, spaces, and bolding.
- Investigate methods of indicating “clickable” areas on a display.
- Investigate tradeoffs between color-coding on text versus color-coding on an associated symbol/icon.

#### Studies Planned for FY09

Follow-up on the FY08 vibration study to examine the effects of different fonts and sizes, line spacing, and color. Complete preparations and training for the Vibration Readability DS0 (first flight scheduled for Feb 2009). Perform a detailed comparative analysis between data collected in a vibration only condition with data collected in g+ vibration (from separately funded effort occurring in Fall 2008) to determine the added value of the centrifuge, and the data lost without the high-g environment.

Investigate the feasibility of performing eye tracking under vibration.

### DISPLAYS – Auditory displays

- Three studies examined the suitability of candidate alarm sounds for four types of alarms: class 1 emergency (fire-smoke and depressurization), class 2 warning and class 3 caution. Crew participants were asked to rate the sounds on a 5-point suitability scale.
- **Emergency (Class 1):** This is the most serious type of event. It is used in a life threatening condition that requires immediate action to protect the crew.
- **Warning (Class 2):** This is less serious than emergency. It is used in a situation that requires immediate attention to avoid or resolve potential issues for the crew.
- **Caution (Class 3):** This is a situation of a less critical nature, with potential for further degradation if crew attention is not given.

Results indicate that the most suitable alarm sound types are based on currently-used alarms.

- Crew results differed from the non-crew slightly (different caution alarm was selected).
- Recommended alarm sounds will be modified per ISO recommendations to reduce the startle effect and accommodate sleeping crew.

#### Studies Planned for FY09

FY09 studies will build on FY08 experiments, attempting to validate previous results, compare results with speech alarms, and examine the impacts of hearing these sounds in a suit.

### EVA OPERATIONS

- **Study on HMD use in lunar lighting**
  - Collaboration with Orion lighting expert in the lighting lab
  - First study to look at HMD in lunar lighting conditions

- **Gloved Dexterity and Tactility**
  - First study to look at glove dexterity in high pressure environment

- **Demonstration of spatially localized beacons**
  - Concept prototype for localizing critical mileposts such as lander, habitat, crewmember

### VIBRATION STUDIES

- **Orion-Ares exposure will be at levels that may exceed the 0.25 g limit imposed by earlier programs during ascent**
- **There is a serious risk that higher vibration will cause unacceptable degradation of human performance, due in part to decrements in visual function**
- **Present study began the process of quantifying this risk by examining how different vibration levels impact ability to make speeded yes/no responses to alphanumeric symbology in a semi-supine position**
- 5 blocks of 60 self-paced trials, 40 with vibration, 20 without
- Each block at one vibration level: 0 g, 15 g, 30 g, 5 g, or 7 g

#### Letter processing task (8 participants)

- Oriente to magenta box
- Do the three letters in the middle row form a word or a non-word?
- Press one button for “Yes”, another for “No”

**Results**

- Errors increased with increased vibration
- There were more errors for smaller compared to larger font
- Vibration effects appeared at smaller vibrations levels for 10 pt font than 14 pt font
- No significant differences between vibration effects on lexical decision and magnitude comparison tasks
- No effects of vibration on follow-up trials
- Response times showed very similar pattern to errors

#### Conclusions

- For both number and letter processing, performance is significantly worse at both 0.5 g and 0.7 g for 10 pt font and at 0.7 g for 14 pt font.
- Vibration levels above 0.3 g (0-to-peak) will significantly compromise the processing of alphanumeric symbology in the currently anticipated Orion display viewing conditions.
