Shape memory alloys (SMAs) are an enabling component in the development of compact, lightweight, durable, high-force actuation systems particularly for use where hydraulics or electrical motors are not practical. However, commercial shape memory alloys based on NiTi are only suitable for applications near room temperature, due to their relatively low transformation temperatures, while many potential applications require higher temperature capability.

Heat-Storage Modules Containing LiNO₃·3H₂O and Graphite Foam
Heat capacity per unit volume has been increased.
NASA’s Jet Propulsion Laboratory, Pasadena, California

A heat-storage module based on a commercial open-cell graphite foam (Poco-Foam or equivalent) imbued with lithium nitrate trihydrate (LiNO₃·3H₂O) has been developed as a prototype of other such modules for use as short-term heat sources or heat sinks in the temperature range of approximately 28 to 30 °C. In this module, the LiNO₃·3H₂O serves as a phase-change heat-storage material and the graphite foam as thermally conductive filler for transferring heat to or from the phase-change material. In comparison with typical prior heat-storage modules in which paraffins are the phase-change materials and aluminum fins are the thermally conductive fillers, this module has more than twice the heat-storage capacity per unit volume.

The use of LiNO₃·3H₂O as a phase-change heat-storage material is not new in itself, but heretofore, it has been used with aluminum fins. Open-cell graphite foam has been used as the thermally conductive filler material in conjunction with paraffin phase-change materials in some prior heat-storage modules but, heretofore, it has not been used with LiNO₃·3H₂O because graphite foam is hydrophobic and, therefore not readily wet by LiNO₃·3H₂O. The novelty of the present development lies in the choice of materials to make it possible to use graphite foam as the filler with LiNO₃·3H₂O in order to exploit the greater (relative to aluminum) specific thermal conductivity of graphite to reduce the mass of filler needed to obtain a given level of thermal performance.

The prototype heat-storage module consists of an LiNO₃·3H₂O-imbued open-cell graphite foam core of 76-percent porosity in an aluminum housing that has a ribbed top that provides a rigid mounting surface for electronics. During fabrication, grooves to receive the ribs were cut into the open-cell graphite foam core (see figure). To overcome the hydrophobicity of the graphite foam to enable the core to absorb the LiNO₃·3H₂O, an organosilicon surfactant was added to the molten LiNO₃·3H₂O in the proportion of 0.3 mass percent.

Also added to the LiNO₃·3H₂O was 1 mass percent of zinc nitrate, which serves as a freezing catalyst to reduce, to an interval of 2 °C, what would otherwise be the susceptibility of LiNO₃·3H₂O to freezing supercooling by as much as 35 °C. With this catalyst, the LiNO₃·3H₂O freezes at 28 °C when cooled from a higher temperature and melts at 30 °C when warmed from a lower temperature.

Precipitation-Strengthened, High-Temperature, High-Force Shape Memory Alloys
Shape memory alloys capable of performing up to 400 °C have been developed for use in solid-state actuator systems.
John H. Glenn Research Center, Cleveland, Ohio

Shape memory alloys (SMAs) are an enabling component in the development of compact, lightweight, durable, high-force actuation systems particularly for use where hydraulics or electrical motors are not practical. However, commercial shape memory alloys based on NiTi are only suitable for applications near room temperature, due to their relatively low transformation temperatures, while many potential applications require higher temperature capability.
