Abstract

Solar Electric & Chemical Propulsion
Technology Applications to a Titan Orbiter/Lander Mission

Several advanced propulsion technology options were assessed for a conceptual Titan Orbiter/Lander mission. For convenience of presentation, the mission was broken into two phases: interplanetary and Titan capture. The interplanetary phase of the mission was evaluated for an advanced Solar Electric Propulsion System (SEPS), while the Titan capture phase was evaluated for state-of-art chemical propulsion (NTO/Hydrazine), three advanced chemical propulsion options (LOX/Hydrazine, Fluorine/Hydrazine, high Isp mono-propellant), and advanced tank technologies. Hence, this study was referred to as a SEPS/Chemical based option. The SEPS/Chemical study results were briefly compared to a 2002 NASA study that included two general propulsion options for the same conceptual mission: an all propulsive based mission and a SEPS/Aerocapture based mission. The SEP/Chemical study assumed identical science payload as the 2002 NASA study science payload. The SEPS/Chemical study results indicated that the Titan mission was feasible for a medium launch vehicle, an interplanetary transfer time of approximately 8 years, an advanced SEPS (30 kW), and current chemical engine technology (yet with advanced tanks) for the Titan capture. The 2002 NASA study showed the feasibility of the mission based on a somewhat smaller medium launch vehicle, an interplanetary transfer time of approximately 5.9 years, an advanced SEPS (24 kW), and advanced Aerocapture based propulsion technology for the Titan capture. Further comparisons and study results were presented for the advanced chemical and advanced tank technologies.
Solar Electric & Chemical Propulsion Technology
Applications to a Titan Orbiter/Lander Mission

2007 Joint Propulsion Conference
Michael Cupples
July 2007
Objectives

- Define the performance of various propulsion options for a conceptual Titan mission

- Propulsion options investigated include
  - NEXT SEPS with chemical propulsive Titan capture

- Compare analysis results with 2002 NASA ISPT study results*
  - NEXT SEPS with Aerocapture at Titan
  - All-propulsive

* Robert Bailey, ISPT Aerocapture Systems Analysis Review, August 2002
Overall Analyses Approach

- Systems Analysis
  - System models
    - Launch Vehicles
    - SEPS
    - Chemical Orbiter

- Mission Analysis
  - Trajectory optimization
    - SEPTOP Optimization Code
  - Launch Vehicle Models
  - Ga/As Array Model
  - Multi-Thruster NGI Models

- Basic figures of merit
  - Titan payload
  - Transfer time
  - Launch vehicle
Global Key Analysis Assumptions

Destination: Titan

Launch vehicles considered: Delta Medium, Delta Heavy, Atlas Medium

Final Titan orbit: Circular 2000 km altitude (NASA ISPT study case choose 1700 km for Titan science orbit)

Reference Payloads: Orbiter\(^2\) 42 kg Science payload + Lander\(^3\) 364 kg = 406 kg total

Solar power array design: Next generation Able UltraFlex structures

Baseline: Dry mass margin = 30% SEPS & 20% Chemical
SEPS propellant contingency = 10%
SEPS propulsion redundancy = 1 DCIU/PPU/Thruster

SEPS System Model

- SEP system models are detailed and incorporate expert based algorithms
- Developed by SAIC, Huntsville Alabama, under contract to NASA’s ISPT program
- Applied to technology assessment activities in support of NASA’s ISPT program
SEP System Assumptions

SEPS Baseline Power

Total array power (end-of-life): 30 kWe @ 1AU
Maximum power to ion propulsion system = 25 kWe
Technology and configuration: Two 15 kWe Ultraflex Arrays, $\alpha \sim 200$ w/kg

SEPS Propulsion

Thruster: NEXT, 3600 sec Isp
NEXT, 4000 sec Isp
High Isp Throttling
Max Power $\sim 6.0$ kWe
40 cm grids

Cases investigated:
4 Thrusters, 25 kWe into IPS
5 Thrusters, 31.25 kWe into IPS

Power Processing Unit: NGI, 6.25 kWe
Propellant management system: NGI
Propellant: Xenon
SEPS Propulsion Contingencies, Redundancy, & Other Assumptions

Baseline Contingencies:
- LV: 2% of LV nominal capacity baseline (10% also investigated)
- Propellant: 10% of total deterministic propellant
- Dry mass: 30% of dry mass
- Power: 5% added to baseline BOL power

Redundancy:
- One extra ion system (thruster, PPU, Propellant Distribution String, & DCIU)

Others:
- Propulsion system duty cycle = 95% baseline
- ACS is provided by Ion Propulsion System during low thrust burn
- ACS is provided by RCS for periods when Ion Propulsion System is not active
- SEPS Housekeeping Power = 0.25 kW
- 2% of array area added to array per year of propulsion power-on time for end-of-life requirements

Conservative analysis margins and contingencies
SOA Chemical Systems: Propellant, Engine, & Tanks

• Baseline Storable; NTO/N₂H₄
  • Examples:
    • TRW ADMLAE Pressure Fed
      • Isp 330 sec
    • Aerojet R-4D-15DM
      • Isp 328 sec
  • Pressure fed
  • Off-the-shelf technology

• Tank Liner Thickness and Composite Overwrap Stress Factor
  • Baseline liner thickness 30 mil
  • Nominal tank stress factor is scaled from AXAF tanks
Chemical Stage Contingencies & Other Assumptions

**Contingencies:**

- **Propellant:** 3.0% of total deterministic propellant
- **Dry Mass:** 20% of total mass (non payload) delivered
- **Power:** Provided by RTG (Radioisotope Thermal Generator) & batteries
- **Structure:** Size based on historical data for actual spacecraft

**Others:**

- 20 m/s total RCS $\Delta V$, includes maintaining proper final parking orbit
- 20 m/s $\Delta V$ for course correction and aimpoint maneuvers
SEPS Saturn Trajectory Sample
8.5 Year, Atlas-V 431

4 NEXT Engines @ 4000 sec Isp
Power = 25 kW into ion propulsion system
PMAx = 6.25 kW (maximum PPU power)
PMIN = 1.39 kW
95% Duty Cycle
Triple Junction GaAs Array

Titan out-of-plane capture modeled and accounted for in analyses
Titan Capture g-loss Analysis

- Altitude Periapsis = 1995.5 km
- Altitude Apoapsis = 2003.3 km
- Thrust = 1000 N (two 100 Ib engines)
- Burn Time = 4210.5 sec
- ΔV (m/s), ideal = 3288; actual = 3345.3
- Propellant mass (kg), ideal = 1287.8, actual = 1300.6
- Propellant Difference = 12.8 kg
- Gravity Loss = 57.3 m/sec
SEPS Payload to Saturn vs. Transfer Time
Launch Vehicle Variation

Launch Vehicle Margin 2%, SEPS Duty Cycle 95%, 4 NEXT Engines, 4000 sec Isp

Launch vehicles investigated cover a SEPS payload range between ~1100 to ~2500 kg
Titan Payload vs. Transfer Time

Baseline NTO/N$_2$H$_4$

For SOA chemical, a minimum LV capacity of Atlas-V 421 is required to accomplish the mission.
Stack Mass
Launch Vehicle Comparison, 4 Ion engines @ 4000 Isp, NTO/N₂H₄

For SOA storable, the mission could be accomplished with the Atlas 421 or Atlas 431.

(1) MSFC PRC Seminar, Oct 29, 2002
SEPS Payload vs Transfer Time
Variation in Number of Operational Thrusters

LV: Atlas 431, 2% contingency

- 5 thruster SEP configuration delivers more mass to Saturn than the 4 thruster configuration

† Nominal maximum power into a PPU = 6.25 kWe
SEPS Payload vs Transfer Time

Variation in Isp of Thruster

LV: Atlas 431, 2% contingency

- 5 thruster SEP configuration delivers more mass to Saturn than the 4 thruster configuration
Advanced Technology Parametric Study
Advanced Chemical Systems: Propellants, Engines, & Tanks

- **Option 1: Advanced Storable; LOX/N₂H₄**
  - 351 lsp
  - Pressure fed, 100 psia chamber pressure
  - Requires active refrigeration of LOX
  - Experimental

- **Option 2: Advanced Storable; F₂/N₂H₄**
  - 380 lsp
  - Pressure fed, 100 psia chamber pressure
  - Very reactive and toxic
    - Fluorine oxidizers react with their containment vessels; internal surfaces must be passivated.
    - Requires active refrigeration of LOX
  - Experimental

- **Option 3: Advanced Storable; Monopropellant**
  - 275 lsp
  - Pressure fed, 100 psia chamber pressure

- **Tank Liner Thickness and Composite Overwrap Stress Factor**
  - Liner thickness 5 mil to 30 mil
  - Stress factor from 70% to 130% of nominal
  - Nominal tank stress factor is scaled from AXAF tanks
Stack Mass
Chemical Technology Comparison

For propellants investigated and for an Atlas 431 LV, significant margin over reference payload of 406 kg can be realized.
Titan Payload vs. Transfer Time

\[ F_2/N_2H_4 \]

- For \( F_2/N_2H_4 \), a minimum LV capacity of Delta-IV 4450 can accomplish the mission
- \( F_2/N_2H_4 \) provides significantly more performance capability than SOA chemical
- Transfer time for the Atlas-V 431 case is less than 6.5 years
Titan Payload vs. Transfer Time

Advanced Monopropellant, 275 sec Isp

- For an advanced monopropellant of 275 sec Isp, a medium LV cannot accomplish the mission
Payload Dependence on Variation in Tank Stress Factor

Nominal 8.5 Year Transfer Time, Atlas 431
NTO/N2H4

- Stress Factor 30% Below Nominal
- Stress Factor Nominal, AXAF SOA
- Stress Factor 30% Above Nominal

Varying tank liner thickness from SOA to 5 mil and reducing required stress factor by 30% from SOA increased payload over the baseline (43 kg) by 50%.
Advanced Propulsion Analyses Conclusions

• NTO/N₂H₄ Propulsion
  - Atlas V 421 is the minimum launch vehicle to deliver the study payload: 67% orbiter payload margin.
  - Atlas V 431 can deliver ISPT study payload with a 215% orbiter payload margin.

• F₂/N₂H₄ Propulsion
  - Provides significant performance increase over NTO/N₂H₄ (Atlas 431 LV): 100 kg of orbiter payload

• LOX/N₂H₄ Propulsion
  - Provides an improvement over NTO/N₂H₄ (Atlas 431 LV) of only 12 kg of orbiter payload: probably does not warrant a new engine development program for 100 lbf class engines

• Monopropellants
  - Provides no improvements over SOA chemical unless the Isp is significantly greater than 275 sec

• Tank Technologies
  - decreasing tank liner thickness and reducing pressure factor can provide a significant increase in payload delivery capability over SOA

• Results indicate that SEP/Chemical systems can accomplish the mission using “conventional” chemical technology:
  - With longer trip times and larger launch vehicles required than the SEP/AC option
  - In much shorter trip times and with smaller launch vehicles than an all-propulsive chemical mission
  - With larger overall stack mass required than SEP/AC option
