A method for applying a mixed metal oxide catalyst to a metallic substrate for the creation of a robust, high temperature catalyst system for use in decomposing propellants, particularly hydrogen peroxide propellants, for use in propulsion systems. The method begins by forming a prepared substrate material consisting of a metallic inner substrate and a bound layer of a noble metal intermediate. Alternatively, a bound ceramic coating, or frit, may be introduced between the metallic inner substrate and noble metal intermediate when the metallic substrate is oxidation resistant. A high-activity catalyst slurry is applied to the surface of the prepared substrate and dried to remove the organic solvent. The catalyst layer is then heat treated to bind the catalyst layer to the surface. The bound catalyst layer is then activated using an activation treatment and calcinations to form the high-activity catalyst system.

APPLICATION OF A MIXED METAL OXIDE CATALYST TO A METALLIC SUBSTRATE

STATEMENT REGARDING FEDERALLY SPONSORED RESEARCH

This invention described herein was made in the performance of work under NASA contract No. NCC8-193 and is subject to the provisions of Section 305 of the National Aeronautics and Space Act of 1958 (72 Stat. 435: 42 U.S.C. 2457).

TECHNICAL FIELD

The present invention generally relates to propulsion systems and more specifically to applying a mixed metal oxide catalyst to a metallic substrate.

BACKGROUND ART

Safer, less toxic propellants that meet operational performance requirements have long been sought by the propulsion industry. The commitment to increasingly safer and lower cost orbit space operations, as evidenced by a central charter of the Space Launch Initiative, has made success in testing less toxic propellants more imperative than ever. Less toxic propulsion systems are being developed to replace engine systems that use more hazardous propellants, such as Nitrogen Tetroxide (NTO) and Monomethyl Hydrazine (MMH).

Hydrogen peroxide offers many potential benefits as a non-toxic propellant source for target, space, and on-orbit applications. Hydrogen peroxide can be decomposed by passing it over a catalyst. The catalyst bed decomposes the hydrogen peroxide to produce super-heated steam and oxygen. The hot gases can be used to drive gas turbines, provide thrust as a monopropellant, provide an oxidizer for a bipropellant system, or function as an igniter for a rocket engine when combined with fuels like kerosene.

Ninety-eight (98%) percent hydrogen peroxide is an excellent oxidizer for many space applications, both in monopropellant and bipropellant systems, because it is non-aryogenic, has high density, and can be used as a regenerative coolant. However, the high adiabatic decomposition temperature of 98% hydrogen peroxide (1734 degrees Fahrenheit at one atmosphere, versus 1364 degrees Fahrenheit for 90% hydrogen peroxide) causes melting of conventional silver-screen catalysts currently used to decompose 90% hydrogen peroxide.

Beyond traditional silver catalysts, many catalysts are already known for the decomposition of hydrogen peroxide. Metals such as gold, platinum and palladium, in addition to oxides such as manganese dioxide, are known to be active catalysts for the decomposition of hydrogen peroxide. However, these catalysts have performance limitations in the decomposition of high concentrations of hydrogen peroxide. These limitations include low melting temperatures, low activity and sensitivity to stabilizers contained in the hydrogen peroxide solutions.

Therefore, there is a need for developing a catalyst system with enhanced temperature capability, high activity and low sensitivity to stabilizers that can safely operate with up to about 99% concentration hydrogen peroxide propellant systems.

Further, a similar need exists for catalyst systems that may be used for the catalytic combustion of hydrocarbon/air mixtures. Such a catalyst system could be used in the power generation or automotive industries for emission control applications.
gas to steam and oxygen that can be subsequently used to drive gas turbines, provide thrust as a monopropellant, provide an oxidizer for bi-propellant systems, or function as an igniter for a rocket engine when combined with fuels like kerosene. The proposed system describes a method for the application of a novel catalyst material \(58\) to a prepared metallic substrate \(50\) for use in an assembly of a catalyst bed \(50\) that can be used to decompose hydrogen peroxide gas into steam and oxygen.

The design of the assembly \(10\) described represents potentially infinite designs that may be used and is illustrated here for understanding of the proposed catalyst system \(58\) and is therefore not intended to be limiting. Preferred unique designs that utilize the proposed catalyst system \(58\) are also illustrated and described in co-pending U.S. application Ser. No. 10/405,049, which is herein incorporated by reference.

Referring now to FIG. 1, a schematic of a gas generator assembly \(10\) is shown as having housing \(20\) consisting of an inlet \(22\) and an outlet \(24\). Liquid hydrogen peroxide propellant \(30\) enters the gas generator assembly through the inlet \(22\). After passing through the inlet \(22\), the hydrogen peroxide liquid enters the catalyst bed \(50\). As will be described further below and in co-pending U.S. application Ser. No. 10/405,049, a novel catalyst material (shown as \(58\) in FIG. 3) decomposes the hydrogen peroxide propellant \(30\) into steam and oxygen, hereinafter referred to as high temperature gas \(40\), that exits the catalyst bed \(50\) and exits the gas generator \(10\) through the outlet \(24\). The high temperature gas \(40\) is then used to drive gas turbines, provide thrust as a monopropellant, provide an oxidizer for bi-propellant systems, or function as an igniter for a rocket engine when combined with fuels like kerosene.

In the preferred embodiment, the catalyst bed \(50\) shown in FIG. 1 is comprised of a stack of catalyst coated wire mesh screens \(51\). FIG. 2 shows a single wire mesh screen \(51\) as used in the assembly of the catalyst bed \(50\) in FIG. 1.

As best shown in FIG. 3, the catalyst-coated screen \(51\) is comprised of an inner metallic wire substrate \(52\). The inner metallic substrate \(52\) is preferably an oxidation resistant alloy. The inner metallic substrate \(52\) is selected based on numerous factors, including catalyst bed operating temperatures (as determined by the concentration of peroxide \(30\)) and the preferred form of the substrate (which includes wire meshes, tubes or corrugated sheets). Preferred inner metallic substrates \(52\) for use in high-percentage hydrogen peroxide propellant systems as shown in FIG. 1 include 16-wire mesh, Type 316 stainless steel screens that have high melting temperatures and oxidation resistance. Three preferred stainless steel screens \(51\) that meet these criteria include CRSS 316, CRSS 347 and CRSS 304, manufactured by Allegheny Ludlum. Another preferred metallic substrate is wire mesh screen of the nickel-based superalloy, Hastelloy C-276, manufactured by Haynes International. (All screens are available from Screen Technology Group, Inc. of Washougal, Wash.)

The metallic substrate \(52\) is surrounded by a noble metal intermediate \(56\). The noble metal intermediate \(56\), or strike, may be a noble metal or noble metal alloy and is used to bond the catalyst \(58\) to the metallic substrate \(52\). The metal intermediate \(56\) may be silver or a silver-palladium alloy.

A ceramic coating \(54\) may be optionally added to the metallic substrate \(52\) prior to introducing the noble metal intermediate \(56\) depending upon the composition of the metallic substrate \(52\). The ceramic coating \(54\) is preferably introduced to provide oxidation protection for the metallic substrate \(52\) and to prevent alloying between the metallic substrate \(52\) and noble intermediate \(56\) during subsequent processing steps requiring high temperatures or during utilization with high concentration peroxide propellants. The ceramic coating \(54\) preferably is a chrome oxide containing enamel frit. Any enamel frit providing good oxidation prevention may be used. One preferred ceramic coating \(54\) is Frit A-418, made by Ferro Corporation. The composition of Frit A-418 is shown below in Table 1:

The ceramic coating \(54\) is surrounded by a noble metal intermediate \(56\). The noble metal intermediate \(56\), or strike, may be a noble metal or noble metal alloy and is used to bond the catalyst \(58\) to the ceramic coating \(54\). The metal intermediate \(56\) may be silver or a silver-palladium alloy. For ease of understanding, the inner metallic substrate \(52\), optional ceramic coating \(54\), and noble metal intermediate \(56\) are hereinafter collectively referred to as the prepared substrate material \(60\).

When the inner metallic substrate \(52\) comprises a high temperature, oxidation resistant alloy, both the ceramic coating \(54\) and the noble metal intermediate \(56\) can be optional. In such a case, the mixed metal oxide catalyst \(58\) can be applied directly to the inner metallic substrate according to the method outlined below.

The prepared substrate material \(60\) is then coated with a mixed metal oxide (MMO) catalyst \(58\). The mixed metal oxide catalyst \(58\) of the present invention is a robust, high-activity catalyst for long duration use with up to about 99% concentration hydrogen peroxide propellant \(30\). As such, the catalyst \(58\) must have a melting temperature greater than the adiabatic decomposition temperature of the hydrogen peroxide propellant \(30\). Two preferred mixed metal oxide catalyst \(58\) compositions have been found to achieve these desired results. These are Type I and Type II catalysts as described in co-pending U.S. application Ser. No. 10/404,934. In these systems, silver (Type I) or a silver-palladium alloy (Type II) are the active catalysts, while the manganese oxide and/or dysprosium oxide constitute co-catalysts (promoters). Alumina is also added to the formulation to enhance surface area, while borosilicate glass is added as a structural binder. One preferred borosilicate glass that may be utilized is Pyrex glass, available from Corning. Finally, gold is added as a promoter. The preferred compositions of the Type I and Type II catalysts are shown below in Tables 2 and 3:

FIG. 4 describes a preferred method for forming the Type I and/or Type II mixed metal oxide catalyst coating as shown in FIG. 2. FIG. 4 also describes the method for applying the catalyst to the prepared substrate and the subsequent activation of the catalyst. Specific details for applying the Type I and Type II catalyst systems to a metallic substrate are illustrated and described in detail below. The details provided in FIG. 4 and the following text, illustrate the preferred method for applying the catalyst systems to metallic substrates.

Referring now to FIG. 4, the process begins in Step 100 by cleaning the inner substrate to remove inorganic materials or contaminants from the surface of the substrate. For example, the stainless steel screen material described above in FIGS. 3 and 4 is introduced to a 60 degrees Celsius (140 degree Fahrenheit) alkaline bath for cleaning. Any metallic substrate, regardless of physical shape or form, would require such a cleaning process.

Next, in Step 110, the optional ceramic coating is applied to the inner substrate as a slurry or paste. Application methods include dipping, spraying, brushing, or air-brushing. In Step 120, the ceramic-coated inner substrate is heat treated to adhere the ceramic coating. The intermediate coating is applied to the inner substrate. For FritA418, as described in FIG. 3, the coated substrate is heat treated for approximately 14 minutes at about 1060 degrees Celsius (1940 degrees Fahrenheit). The final ceramic coating thickness, after firing, is between 10 and 100 microns. The ceramic coating is not required for oxidation resistant alloys that do not form excessive oxidation products or react with the intermediate metallic layer described below.

Next, in Step 130, the noble metal intermediate, or strike, is applied either to the coated inner substrate or ceramic coating, depending upon the composition of the inner substrate or the operating conditions for utilizing the catalyst as described above. The intermediate as described above is noble metal or noble metal alloy and is applied as a paste or slurry. In Step 140, a subsequent heat treatment binds the intermediate to the coated inner substrate or ceramic coating, thereby forming the prepared substrate. Where silver is used as the intermediate, the heat treatment of Step 140 is performed by slowly heating the intermediate coated screens from room temperature to about 925 degrees Celsius (1700 degrees Fahrenheit) to drive off any organic solvents, and holding the temperature at 925 degrees Celsius for 10 to 20 minutes to fuse the silver to the ceramic coating. After the hold, the screens are removed from the furnace. The thickness of the fused intermediate coating is uniform and preferably has a thickness of between 10 and 100 microns.

In Step 150, the constituent dry powders of the catalyst as described in either Table 2 or Table 3 above are weighed out and placed in a suitable container for blending. The powders of each constituent should not exceed about 10 microns to ensure good catalytic activity. The actual powder size is dependent upon the actual application method chosen below.

Next, in Step 155, the ceramic-coated inner substrate is heat treated to bind the mixed metal oxide catalyst material to the prepared substrate. To achieve this, the catalyst-coated substrate is introduced to an air furnace oven that is initially kept at or below about 150 degrees Celsius (300 degrees Fahrenheit). The furnace temperature is slowly increased to between approximately 840 and 1040 degrees Celsius (1550-1900 degrees Fahrenheit) and held at this temperature for about 30 to 240 minutes, depending upon the formulation of the catalyst material. After the prescribed hold, the part is slowly cooled to room temperature in an air atmosphere. After firing, the catalyst coating should be uniform in appearance and between 10 and 400 microns in thickness.

For the Type I catalysts shown in Table 2 and for the Type II catalysts shown in Table 3, a heat treatment to 925 degrees Celsius with a hold of about 120 minutes is preferred.

Next, in Step 170, the mixed metal oxide catalyst receives an appropriate activation treatment. Next, in Step 180, the applied activation treatment is calcined in an air furnace. The process of Steps 170 and 180 may be repeated as desired.

For metallic substrates with the Type I catalyst system applied, the activation treatment consists of a samarium nitrate hexahydrate solution. The solution is prepared and applied to the coated substrate by dipping, brushing, spraying or air-brushing and allowed to dry. After drying, the solution is calcined in an air furnace for approximately 30 minutes at about 175 degrees Celsius (350 degrees Fahrenheit). The process is repeated for a total of between 3 and 5 calcining cycles.

For metallic substrates with the Type II catalyst system applied, the activation treatment consists of a noble metal loaded nitric acid solution. The solution is prepared by fully dissolving a portion of the silver-palladium alloy (shown in Table 2 above) in concentrated nitric acid. The solution is then applied to the catalyst coated substrate by dipping, brushing, spraying or air-brushing and allowed to dry. After drying, the solution is calcined in an air furnace for approximately 20 minutes at about 230 degrees Celsius (450 degrees Fahrenheit). The process is repeated for a total of between 2 and 5 calcining cycles.

In addition, the catalysts as described above can be used in other propellant decomposition systems. For example, the Type II catalyst, applied to a metallic substrate, has been used in the catalytic combustion of methane. This indicates that these catalysts may be used in the catalytic combustion or decomposition of other hydrocarbon propellants.

While the invention has been described in terms of preferred embodiments, it will be understood, of course, that the invention is not limited thereto since modifications may be made by those skilled in the art, particularly in light of the foregoing teachings.

What is claimed is:
1. A method for applying a mixed metal oxide catalyst system to a metallic substrate to form a high-temperature catalyst for use in the decomposition of hydrogen peroxide or other propellant comprising:

- providing a prepared metallic substrate;
- forming a high-activity catalyst composition, wherein said high-activity catalyst composition comprising between about 10 to 20 weight percent of alumina and being selected from the group consisting of a Type I catalyst composition and a Type II catalyst composition;
- combining an organic solvent with said high-activity catalyst composition to form a catalyst slurry, said organic solvent being volatile under gentle heating;
- applying a layer of said catalyst slurry to said prepared metallic substrate;
- drying said catalyst slurry applied on said prepared metallic substrate to form a layer of a catalyst material on said prepared substrate to form a catalyst coated prepared substrate;
- binding said layer of catalyst material to said prepared metallic substrate thus forming a binded layer on said prepared substrate;
- applying an activation treatment to said binded layer, and calcining said activation treatment to said binded layer.

2. The method of claim 1, wherein forming a high-activity catalyst composition comprises dry blending a plurality of ingredients comprising said high-temperature catalyst powder comprising:

- about 0 to 20 weight percent of silver-palladium alloy;
- about 10 to 20 weight percent of manganese dioxide;
- about 0 to 20 weight percent of dysprosium oxide;
- about 0 to 40 weight percent of borosilicate glass;
- about 0 to 40 weight percent of dysprosium oxide;
- about 0 to 20 weight percent of boric acid.

3. The method of claim 2, wherein introducing said catalyst coated prepared metallic substrate to an oven having a temperature below 300 degrees Fahrenheit after the heat treatment.

4. The method of claim 2, wherein providing a prepared metallic substrate comprises:

- applying a samarium nitrate hexahydrate solution to a high-temperature alloy substrate.

5. The method of claim 4, wherein introducing said catalyst coated prepared metallic substrate to a high-temperature alloy substrate comprises:

- applying an activation treatment to said binded layer and calcining said activation treatment comprises:
  - (a) dissolving a portion of said silver-palladium alloy into a solution of concentrated nitric acid to form a loaded nitric acid solution;
  - (b) applying said loaded nitric acid solution to said binded layer;
  - (c) drying said loaded nitric acid solution to said binded layer;
  - (d) introducing said binded layer having said dried loaded nitric acid layer to an air furnace having a temperature of approximately 450 degrees Fahrenheit;
  - (e) calcining said binded layer for approximately 20 minutes;
  - (f) repeating steps (a) through (e) between 1 and 4 times.

6. The method of claim 1, wherein binding said layer of catalyst material to said metallic substrate comprises:

- providing a high-temperature alloy substrate.

7. The method of claim 6, wherein applying a layer of ceramic coating to said high-temperature alloy substrate to form a prepared metallic substrate comprises:

- applying a layer of ceramic coating to said high-temperature alloy substrate; and
- heat treating said layer of ceramic coating to adhere said layer of ceramic coating to said high-temperature alloy substrate.

8. The method of claim 7, wherein each of said plurality of ingredients comprising said high-temperature catalyst powder has an initial form of a powder having an average particle size is about 10 microns or less.

9. The method of claim 1, wherein providing an activation treatment to said binded layer of said catalyst material comprises:

- (a) dissolving a portion of said silver-palladium alloy into a solution of concentrated nitric acid to form a loaded nitric acid solution;
- (b) applying said loaded nitric acid solution to said binded layer;
- (c) drying said loaded nitric acid solution to said binded layer;
- (d) introducing said binded layer having said dried loaded nitric acid layer to an air furnace having a temperature of approximately 450 degrees Fahrenheit;
- (e) calcining said binded layer for approximately 20 minutes; and
- (f) repeating steps (a) through (e) between 1 and 4 times.

10. The method of claim 6, wherein applying a layer of a ceramic coating to said high-temperature alloy substrate comprises:

- providing a high-temperature alloy substrate; and
- heat treating said layer of ceramic coating to adhere said layer of ceramic coating to said high-temperature alloy substrate.

11. The method of claim 1, wherein forming a high-activity catalyst composition comprises dry blending a plurality of ingredients to form a high-activity catalyst powder, said high-activity catalyst powder comprising:

- about 30 to 50 weight percent of silver-palladium alloy;
- about 0 to 40 weight percent of manganese dioxide;
- about 10 to 20 weight percent of dysprosium oxide;
- about 0 to 20 weight percent of boric acid.

12. The method of claim 11, wherein each of said plurality of ingredients comprising said high-temperature catalyst powder has an initial form of a powder having an average particle size is about 10 microns or less.

13. The method of claim 11, wherein applying an activation treatment to said binded layer of said catalyst material comprises:

- (a) dissolving a portion of said silver-palladium alloy into a solution of concentrated nitric acid to form a loaded nitric acid solution;
- (b) applying said loaded nitric acid solution to said binded layer;
- (c) drying said loaded nitric acid solution to said binded layer;
- (d) introducing said binded layer having said dried loaded nitric acid layer to an air furnace having a temperature of approximately 450 degrees Fahrenheit;
- (e) calcining said binded layer for approximately 20 minutes; and
- (f) repeating steps (a) through (e) between 1 and 4 times.

14. The method of claim 1, wherein binding said layer of catalyst material to said metallic substrate comprises:

- providing a high-temperature alloy substrate.

15. The method of claim 1, wherein providing a prepared metallic substrate comprises:

- applying a high-temperature alloy substrate; and
- applying a layer of a ceramic coating to said high-temperature alloy substrate to form a prepared metallic substrate.

16. The method of claim 15, wherein applying a layer of a ceramic coating to said high-temperature alloy substrate to form a prepared metallic substrate comprises:

- applying a layer of ceramic coating to said high-temperature alloy substrate; and
- heat treating said layer of ceramic coating to adhere said layer of ceramic coating to said high-temperature alloy substrate.

17. The method of claim 16, wherein each of said plurality of ingredients comprising said high-temperature catalyst powder has an initial form of a powder having an average particle size is about 10 microns or less.

18. The method of claim 1, wherein providing a prepared metallic substrate comprises:

- providing a high-temperature alloy substrate; and
- heat treating said layer of ceramic coating to adhere said layer of ceramic coating to said high-temperature alloy substrate.

19. The method of claim 18, wherein each of said plurality of ingredients comprising said high-temperature catalyst powder has an initial form of a powder having an average particle size is about 10 microns or less.

20. The method of claim 19, wherein applying a layer of a ceramic coating to said high-temperature alloy substrate comprises:

- providing a high-temperature alloy substrate; and
- heat treating said layer of ceramic coating to adhere said layer of ceramic coating to said high-temperature alloy substrate.

21. The method of claim 20, wherein each of said plurality of ingredients comprising said high-temperature catalyst powder has an initial form of a powder having an average particle size is about 10 microns or less.
applying a layer of a ceramic coating to said high-temperature alloy substrate; and
applying a layer of a noble metal intermediate to said ceramic coating to form a prepared substrate.

19. The method of claim 18, wherein applying a noble metal intermediate to said ceramic coating to form a prepared metallic substrate material comprises:
introducing a layer of silver to said layer of said ceramic coating; and
heat treating said layer of silver to bind said layer of silver to said layer of said ceramic coating.

20. The method of claim 18, wherein applying a noble metal intermediate to said ceramic coating to form a prepared metallic substrate comprises:
introducing a layer of a silver-palladium alloy to said ceramic coating; and
heat treating said layer of said silver-palladium alloy to bind said layer of silver-palladium alloy to said ceramic coating.

21. The method of claim 1, wherein providing a prepared metallic substrate comprises:
providing a high-temperature alloy substrate; and
applying a layer of noble metal intermediate to said high-temperature alloy substrate to form a prepared metallic substrate.

22. The method of claim 21, wherein applying a noble metal intermediate to said high-temperature alloy substrate to form a prepared metallic substrate material comprises:
introducing a layer of silver to said high-temperature alloy substrate; and
heat treating said layer of silver to bind said layer of silver to said high-temperature alloy substrate.

23. The method of claim 21, wherein applying a noble metal intermediate to said ceramic coating to form a prepared metallic substrate comprises:
introducing a layer of silver-palladium alloy to said high-temperature alloy substrate; and
heat treating said layer of silver-palladium alloy to bind said layer of silver-palladium alloy to said high-temperature alloy substrate.
