An apparatus and method for automated monitoring of airborne bacterial spores. The apparatus is provided with an air sampler, a surface for capturing airborne spores, a thermal lysis unit to release DPA from bacterial spores, a source of lanthanide ions, and a spectrometer for excitation and detection of the characteristic fluorescence of the aromatic molecules in bacterial spores complexed with lanthanide ions. In accordance with the method: computer-programmed steps allow for automation of the apparatus for the monitoring of airborne bacterial spores.

APPROPRIATION AND METHOD FOR AUTOMATED MONITORING OF AIRBORNE BACTERIAL SPORES

CROSS REFERENCE TO RELATED APPLICATIONS

This application claims priority to U.S. Provisional Ser. No. 60/671,918 for “Automated Monitoring of Airborne Bacterial Spores” filed on Apr. 15, 2005, incorporated herein by reference in its entirety. This application may also be related to U.S. Ser. No. 10/306,331 filed on Nov. 27, 2002 and U.S. Ser. No. 10/355,462 filed on Jan. 31, 2003, both of which are incorporated herein by reference in their entirety. The present application may also be related to U.S. Ser. No. 11/810,005 filed on Jun. 4, 2007, to U.S. Ser. No. 11/453,296, filed on Jun. 13, 2006, and to U.S. Ser. No. 11/332,788 filed on Jan. 12, 2006.

STATEMENT OF GOVERNMENT SUPPORT

The present invention was made with support from the United States Government under Grant number NAS7-1407 awarded by NASA. The United States Government has certain rights in the invention.

BACKGROUND

Bacterial endospores are highly resistant, thick walled structures formed by vegetative cells during a process called sporulation, and they are quite possibly the most resistant forms of life (Hindle and Hall, 1999 Analyst, 124, 1599-1604). They are highly resistant to radiation, chemical agents, dessication, and other normally harmful environments (Nicholson, W. L. et al. 2000. Microbiol Molecular Biol. Rev., 64, 548). Several bacterial genera are capable of producing endospores; Bacillus and Clostridium are the two most common endospore-producing genera. Within the Bacillus genus is the species Bacillus anthracis the causative agent for anthrax.

Current methods for rapidly detecting airborne bacterial spores that can carry toxins, such as those that cause anthrax, are prohibitively costly to implement and maintain. Additionally, the present monitoring methods are limited by the use of species-specific antigens and DNA probes, which would not detect a seemingly benign species that is modified to carry the anthrax toxin (Koehler, T. M. 2002. Current Topics in Microbiology & Immunology, 271, 143-164; Uchida, I. 1991. J. Bacteriol. 175, 5329-5338).

Therefore, what is needed is an automated apparatus for rapidly detecting bacterial spores that is less costly and not limited to a particular species or DNA sequence.

SUMMARY

According to a first aspect of the present disclosure, an apparatus for the detection of airborne bacterial spores, wherein the apparatus comprises: an air sampler comprising an intake; a surface connectable to the air sampler suitable for spore adhesion; a thermal lysis unit for lysing the spores on the surface resulting in release of DPA; a source of lanthanide ions for providing lanthanide ions to the released DPA on the surface to form a DPA-lanthanide complex; a thermal lysis unit for lysing the spores, wherein the apparatus comprises: an air sampler proximal to the source of lanthanide ions; (e) operating the thermal lysis unit off of the surface to a position proximal to the source of lanthanide ions; (f) moving the surface to a position away from the source of lanthanide ions to a position proximal to the thermal lysis unit; (g) operating the spectrometer to expose the surface to the UV source, thereby exciting said DPA-lanthanide complex and producing fluorescence; (h) operating the spectrometer to detect the fluorescence resulting from the excited DPA-lanthanide complex of step (g); and (i) quantifying the fluorescence intensity and/or imaging the fluorescence of step (h).

According to a second aspect of the present disclosure, a method for the apparatus as disclosed above is provided, the method comprising the steps of: (a) operating the air sampler to deposit sampled air onto the surface; (b) moving the surface from the air sampler to a position proximal to the thermal lysis unit; (c) positioning the thermal lysis unit onto the surface, thereby allowing for thermal lysis of any spores on the surface, thus releasing DPA from any lysed spores; (d) positioning the thermal lysis unit off of the surface to a position proximal to the source of lanthanide ions; (e) operating the source of lanthanide ions to provide lanthanide ions to the surface, thereby putting the lanthanide ions in contact with any DPA on the surface, resulting in said DPA-lanthanide complex; (f) moving the surface to a position away from the source of lanthanide ions to a position proximal to the thermal lysis unit; (g) moving the thermal lysis unit onto the surface, thereby allowing for thermal lysis of any spores on the surface, thus releasing DPA from any lysed spores, and putting DPA in contact with the lanthanide ions provided to the surface in step (c) to form said DPA-lanthanide complex; (h) moving the thermal lysis unit off of the surface to a position proximal to a spectrometer comprising a UV source; (g) operating the spectrometer to expose the surface to the UV source, thereby exciting said DPA-lanthanide complex and producing fluorescence; (h) operating the spectrometer to detect the fluorescence resulting from the excited DPA-lanthanide complex of step (g); and (i) quantifying the fluorescence intensity and/or imaging the fluorescence of step (h).

According to a third aspect of the present disclosure, a method for the apparatus as disclosed above is provided, the method comprising the steps of: (a) operating the air sampler to deposit sampled air onto the surface; (b) moving the surface from the air sampler to a position proximal to a source of lanthanide ions; (c) operating the source of lanthanide ions to provide lanthanide ions to the surface; (d) moving the surface to a position away from the source of lanthanide ions to a position proximal to the thermal lysis unit; (e) moving the thermal lysis unit onto the surface, thereby allowing for thermal lysis of any spores on the surface, thus releasing DPA from any lysed spores, and putting DPA in contact with the lanthanide ions provided to the surface in step (c) to form said DPA-lanthanide complex; (f) moving the thermal lysis unit off of the surface to a position proximal to a spectrometer comprising a UV source; (g) operating the spectrometer to expose the surface to the UV source, thereby exciting said DPA-lanthanide complex and producing fluorescence; (h) operating the spectrometer to detect the fluorescence resulting from the excited DPA-lanthanide complex of step (g); and (i) quantifying the fluorescence intensity and/or imaging the fluorescence of step (h).

One advantage of a bacterial monitor of the present disclosure, is that the chemical marker used for detection—DPA—is essential to the viability of the bacterial spore yet is present whether the spores are alive or dead. Furthermore, since approximately 10^9 molecules of DPA are present in each bacterial spore as compared to 1 copy of DNA, expensive sample amplification schemes are not required, which significantly lowers the complexity and cost of the monitoring apparatus. Furthermore, DPA binding to terbium exhibits a million-fold greater binding constant than amino acids or nucleic acids.

Another advantage of the present disclosure is that it is not susceptible to false positives due to natural fluctuations in bacterial spore concentrations because these fluctuations occur in a concentration regime many orders of magnitude lower (natural concentrations range from 0.01-0.5 bacterial spores per liter of air) than those, for example, present during an anthrax attack (Pastuszka, J. S. et al., 2000, Atmospheric Environment, 34, 3833-3842).

A further advantage of the present disclosure is that unlike other fluorescence detection methods, the DPA triggered lanthanide luminescence method for bacterial spore detection is not mired by varying background fluorescence from interfer-
DISCLOSED INVENTION

A method of detecting bacterial spores comprises the steps of: providing an apparatus; wherein the apparatus comprises an air sampler, a surface connectable to the air sampler suitable for capturing spores from the air, a thermal lysis unit for lysing the spores on the surface resulting in fluorescence and detection of the fluorescence, and an alarm programmed to sound at a specific fluorescence threshold.

In another embodiment, the apparatus provided in the present disclosure is an automated apparatus that does not require outside intervention apart from establishing the program parameters and fluorescence threshold. This automated apparatus further comprises a computer program as outlined in FIG. 3. The air sampler (1) of the present disclosure can be of any type so long as it allows for the capture of bacterial spores from the air. Commonly this will be a type of filter tape that is directly attached to the air sampler (Example 2). Examples of surfaces for capturing the spores in the sampled air are, but are not limited to, one of the following: quartz fiber tape, electrostatically charged tape and polymer tape. The term "tape" herein refers to any surface that allows for the passage of gases in the air, and will capture microscopic species such as bacterial spores.

Rapid detection of bacterial spores of the present disclosure is based on dipicolinic acid (DPA)-triggered lanthanide ion (terbium, europium) luminescence (Hindle and Hall, 1999 Analyt. Chem. 216). The released DPA binds the lanthanide ions with high affinity and triggers intense green luminescence under UV excitation.

An apparatus according to the present disclosure herein, enables the automated monitoring of aerosolized bacterial spores by implementing a lanthanide (terbium or europium) ion luminescence assay (U.S. patent application Ser. No. 10/306,331; U.S. patent application Ser. No. 10/355,462) in conjunction with a computer-operated apparatus comprising: an aerosol capture device (air sampler) (1) (FIGS. 1, 2) a surface (2) for adherence of the spores captured by the air sampler (e.g. quartz fiber tape), a thermal lysis unit (3) to induce bacterial spore lysis, a source of lanthanide ions (4) for providing terbium or europium ions to the DPA released from the lysed spores, a lifetime-gated luminescence spectrometer (5) with UV source for excitation and subsequent detection of the DPA-lanthanide complex, an alarm programmed to sound at a specific fluorescence threshold, as well as a computer programmed to control the apparatus (FIGS. 2, 3).

In one embodiment of the present disclosure, an automated apparatus is provided for the detection of airborne bacterial spores, wherein the apparatus comprises an air sampler, and a surface connectable to the air sampler suitable for capturing spores from the air.

In a second embodiment of the present disclosure, an apparatus is provided for the detection of airborne bacterial spores, wherein the apparatus comprises an air sampler, a surface connectable to the air sampler suitable for capturing spores from the air, a thermal lysis unit for lysing the spores on the surface resulting in the release of DPA, a source of lanthanide ions for providing lanthanide ions to the released DPA to form a complex, a lifetime-gated fluorescence spectrometer with a UV source for excitation of the DPA-lanthanide complex resulting in fluorescence and detection of the fluorescence, and an alarm programmed to sound at a specific fluorescence threshold.
In another embodiment, the apparatus of the present disclosure is computer-operated (FIGS. 2, 3). A computer-operated/automated apparatus comprises a computer that is programmed to control each component of the apparatus. This automated apparatus does not require outside intervention apart from establishing the program parameters and other computer input functions. This automated apparatus further comprises a computer program as outlined in FIG. 3.

For example, in an automated detector of the present disclosure, the air sampler (1) is controlled by a computer program and motorized nozzle (8) to deposit the sampled air onto a surface (2) connectable to the air sampler (S3, FIG. 3). The air sampler is further controlled with respect to the length of air sampling time. The surface for deposit of the air sample is defined as anything to which spores in the air will adhere. The surface of an automated apparatus is positioned by way of computer and motorized spools (6) that are programmed to move from a position proximal to the air sampler to a position proximal to a thermal lysis unit (3).

Movement of the thermal lysis unit is also controlled by way of a computer and motorized arm (9) allowing for the thermal lysis unit to be moved from a position proximal to the surface to a position in contact with the surface, thereby allowing for thermal lysis of any spores on the surface (S4, FIG. 3).

The temperature of the lysis unit and the length of contact with the surface are parameters of the computer program. After the lysis unit provides heat to the surface, the lysis unit is computer and motor controlled to move from the surface. Once this has occurred, by way of the computer program and motorized spools, the surface moves to a position proximal to a lanthanide source (4).

The lanthanide source contains, preferably terbium ions, but could also contain europium ions. Through the programmed commands of the computer, the lanthanide source provides the lanthanide ions (S5, FIG. 3) to the surface by way of a dropper (10). In this way, lanthanide ions are in contact with any lysed spores on the surface, which as a result of lysis, allow for the formation of DPA-lanthanide complexes on the surface. After the lanthanide sources are provided to the surface, the computer program and motorized spools move the surface to a position proximal to a spectrometer (5).

The spectrometer is programmed to administer UV light via a Xenon flash lamp (laser or UV LED can also be used). This UV light exposure of the DPA-lanthanide complex excites the complex, thereby creating a fluorescence which is detected using the lifetime-gated fluorescence spectrometer, and captured as a computer image (S6, S7, FIG. 3). Such an automated apparatus as disclosed is shown in FIG. 2.

The computer is further programmed to sound an alarm if the sampled air results in a fluorescence that exceeds or meets a programmed threshold fluorescence (S2, S8, FIG. 3). A flow chart detailing the computerized functions for operating the apparatus is shown in FIG. 3.

In an additional embodiment, the apparatus of the present disclosure is programmed to continually sample air, thus the steps from air sampling to analyzing the fluorescence as disclosed can be programmed to continually repeat, or repeat for a given period of time.

In an alternative embodiment, after the surface is moved from the air sampler, the surface can be moved to a position proximal to a lanthanide source for lanthanide ions, and then subsequently moved to a position proximal to the thermal lysis unit. In other words, the thermal lysis step (S4) and the step of providing lanthanide ions (S5) can be transposed.
An apparatus for the detection of airborne bacterial spores, wherein the apparatus comprises:

- an air sampler comprising an intake;
- a surface connectable to the air sampler, the surface suitable for spore adhesion and on-surface spore detection;
- a thermal lysis unit for lysing the spores on the surface resulting in release of dipicolinic acid (DPA);
- a source of lanthanide ions for providing lanthanide ions to the released DPA on the surface to form a DPA-lanthanide complex; and
- a lifetime-gated fluorescence spectrometer having a UV source for on-surface excitation of the DPA-lanthanide complex resulting in fluorescence and subsequent detection of the fluorescence from the surface, wherein the surface is connectable to the air sampler through a relative movement between the surface and the air sampler.

2. The apparatus of claim 1, wherein the air sampler is moveable between a first condition where the air sampler is proximal to the surface, and a second condition where the air sampler forms an airtight seal with the surface.

3. The apparatus of claim 1, further comprising at least two spools, the surface connectable to the intake of the air sampler being located on said spools.

4. The apparatus of claim 1, wherein the surface connectable to the air sampler is selected from the group consisting of:

- quartz fiber tape, electrostatically charged tape and polymer tape.

5. The apparatus of claim 1, wherein the thermal lysis unit is selected from the group consisting of a canusterizer and a soldering iron.

6. The apparatus of claim 1, wherein the source of lanthanide ions comprises terbium ions.

7. The apparatus of claim 1, wherein the source of lanthanide ions comprises europium ions.

8. The apparatus of claim 1, wherein the source of lanthanide ions comprises a reservoir comprising a dropper for providing lanthanide ions to the surface.

9. The apparatus of claim 1, wherein the UV source is selected from the group consisting of a Xenon flash lamp, a laser, and a UV LED.

10. The apparatus of claim 1, wherein the apparatus is further comprising an arrangement for relative movement between the surface and the air sampler to adapt the apparatus to multiple detections, each detection occurring on a different portion of the surface.

11. A method for the operation of the apparatus of claim 1, the method comprising steps of:

(a) operating the air sampler to deposit sampled air onto the surface;
(b) moving the surface from the air sampler to a position proximal to the thermal lysis unit; (c) positioning the thermal lysis unit onto the surface thereby allowing for thermal lysis of any spores on the surface, thus releasing DPA from any lysed spores; (d) positioning the thermal lysis unit off of the surface to a position away from the source of lanthanide ions to a position proximal to the thermal lysis unit; (e) moving the thermal lysis unit onto the surface, thereby allowing for thermal lysis of any spores on the surface, thus releasing DPA from any lysed spores, and putting DPA in contact with the lanthanide ions provided to the surface in step (c) to form said DPA-lanthanide complex; (f) moving the thermal lysis unit off of the surface to a position proximal to the spectrometer comprising a UV source; (g) operating the spectrometer to excite the surface to the UV source, thereby exciting said DPA-lanthanide complex and producing fluorescence; (h) operating the spectrometer to detect the fluorescence resulting from the excited DPA-lanthanide complex of step (g); and (i) quantifying the fluorescence intensity and/or imaging the fluorescence of step (h).

12. A method for the operation of the apparatus of claim 1, the method comprising steps of:

(a) operating the air sampler to deposit sampled air onto the surface; (b) moving the surface from the air sampler to a position proximal to a source of lanthanide ions; (c) operating the source of lanthanide ions to provide lanthanide ions to the surface; (d) moving the surface to a position away from the source of lanthanide ions to a position proximal to the thermal lysis unit; (e) moving the thermal lysis unit onto the surface, thereby allowing for thermal lysis of any spores on the surface, thus releasing DPA from any lysed spores, and putting DPA in contact with the lanthanide ions provided to the surface in step (c) to form said DPA-lanthanide complex; (f) moving the thermal lysis unit off of the surface to a position proximal to the spectrometer comprising a UV source; (g) operating the spectrometer to excite the surface to the UV source, thereby exciting said DPA-lanthanide complex and producing fluorescence; (h) operating the spectrometer to detect the fluorescence resulting from the excited DPA-lanthanide complex of step (g); and (i) quantifying the fluorescence intensity and/or imaging the fluorescence of step (h).

13. The apparatus of claim 1, further comprising a computer and/or an alarm programmed to sound at a specific fluorescence threshold, the computer comprising a computer program to control automation of said apparatus.

14. The apparatus of claim 1, wherein the apparatus is further comprising a computer and/or an alarm programmed to sound at a specific fluorescence threshold, the computer comprising a computer program to control automation of said apparatus.

15. The apparatus of claim 1, wherein the apparatus is adapted for multiple detections each detection occurring on a different portion of the surface, through a relative movement between the surface and the air sampler.

16. The apparatus of claim 1, further comprising an arrangement for relative movement between the surface and the air sampler to adapt the apparatus to multiple detections, each detection occurring on a different portion of the surface.

17. An apparatus for the detection of airborne bacterial spores, wherein the apparatus comprises:

- an air sampler comprising an intake;
- a surface connectable to the air sampler, the surface suitable for spore adhesion and on-surface spore detection;
- a thermal lysis unit for lysing the spores on the surface resulting in release of dipicolinic acid (DPA);
- a source of lanthanide ions for providing lanthanide ions to the released DPA on the surface to form a DPA-lanthanide complex; and
- a lifetime-gated fluorescence spectrometer having a UV source for on-surface excitation of the DPA-lanthanide complex resulting in fluorescence and subsequent detection of the fluorescence from the surface, wherein the surface is connectable to the air sampler through a relative movement between the surface and the air sampler.

18. The apparatus of claim 17, wherein the apparatus is adapted for multiple detections each detection occurring on a different portion of the surface, through a relative movement between the surface and the air sampler.

19. The apparatus of claim 17, further comprising an arrangement for relative movement between the surface and
20. An apparatus for the detection of airborne bacterial spores, wherein the apparatus comprises:

- an air sampler comprising an intake;
- a surface connectable to the air sampler, the surface suitable for spore adhesion and on-surface spore detection;
- a thermal lysis unit for lysing the spores on the surface resulting in release of dipicolinic acid (DPA);
- a source of lanthanide ions for providing lanthanide ions to the released DPA on the surface to form a DPA-lanthanide complex; and
- a lifetime-gated fluorescence spectrometer having a UV source for on-surface excitation of the DPA-lanthanide complex resulting in fluorescence and subsequent detection of the fluorescence from the surface, wherein the surface is connectable to the source of lanthanide ions or the lifetime-gated fluorescence spectrometer through a relative movement of the surface with respect to the source of lanthanide ions or the lifetime-gated fluorescence spectrometer.

21. The apparatus of claim 20, wherein the apparatus is adapted for multiple detections each detection occurring on a different portion of the surface, through a relative movement between the surface and source of lanthanide ions or the lifetime-gated fluorescence spectrometer.

22. The apparatus of claim 20, further comprising an arrangement for relative movement between the surface and the source of lanthanide ions or the lifetime-gated fluorescence spectrometer to adapt the apparatus to multiple detections, each detection occurring on a different portion of the surface.

23. A method for the operation of the apparatus of claim 13, the method comprising steps of: (a) operating the air sampler to deposit sampled air onto the surface; (b) moving the surface from the air sampler to a position proximal to the thermal lysis unit; (c) positioning the thermal lysis unit onto the surface, thereby allowing for thermal lysis of any spores on the surface, thus releasing DPA from any lysed spores; (d) positioning the thermal lysis unit off of the surface to a position proximal to the source of lanthanide ions; (e) operating the source of lanthanide ions to provide lanthanide ions to the surface, thereby putting the lanthanide ions in contact with any DPA on the surface, resulting in a DPA-lanthanide complex; (f) moving the surface to a position away from the source of lanthanide ions to a position proximal to the spectrometer comprising a UV source; (g) operating the spectrometer to expose the surface to the UV source, thereby exciting the DPA-lanthanide complex and producing fluorescence; (h) operating the spectrometer to detect the fluorescence resulting from the excited DPA-lanthanide complex of step (g); and (i) quantifying the fluorescence intensity and/or imaging the fluorescence of step (h); (j) comparing the fluorescence of step (h) with a programmed fluorescence threshold; (k) sounding the alarm if the fluorescence of step (h) exceeds and/or meets the programmed fluorescence threshold.
