A computer-based system for configuring and displaying information on changes in, and present status of, a collection of events associated with a project. Classes of icons for decision events, configurations and feedback mechanisms, and timelines (sequential and/or simultaneous) for related events are displayed. Metadata for each icon in each class is displayed by choosing and activating the corresponding icon. Access control (viewing, reading, writing, editing, deleting, etc.) is optionally imposed for metadata and other displayed information.

CONTEXT BASED CONFIGURATION MANAGEMENT SYSTEM

ORIGIN OF THE INVENTION

This invention was made, in part, by one or more employees of the U.S. government. The U.S. government has the right to make, use and/or sell the invention described herein without payment of compensation, including but not limited to payment of royalties.

FIELD OF THE INVENTION

This invention relates to monitoring and visually presenting information, in a decision tree, on a work flow process and status of and change in a document or operation.

BACKGROUND OF THE INVENTION

One problem faced in managing all or part of a large, complex project is determining, at an arbitrary time, the present status of each relevant activity associated with the project and the history of each of these activities. Project activities can be divided into classes, such as decisions, configurations and feedback/communication aspects. For complex projects, it would be helpful if each activity in a class could have an intuitive or self-evident icon or symbol that is clearly associated with that activity.

What is needed is a visually-based system that indicates, preferably using a single intuitive symbol, icon or other indicium, present status of a decision or activity or configuration (“objects”), recent relevant change(s) in the activity statement or the status of, or constraints imposed on, the decision or activity. Preferably, the flexible indicia can be modified to reflect the most important aspects of the activity. Preferably, each (similar) activity should have a distinguishable indicium that is easily recognized by a system user.

SUMMARY OF THE INVENTION

These needs are met by the invention, which provides a visual and textual system, including a set of intuitive icons representing different activities, for indicating status of and/or change in a document or documents and/or in project operations, using the icons to indicate the presence of different classes of changes that have been introduced in the version displayed. In one embodiment, three distinct classes of status changes are indicated, each class using one of several visually distinguishable icons to indicate the class and providing including additional textual information associated with the icon. Icons from different classes of activities have different shapes, to allow easier distinction between the classes.

The Context Based Configuration Management (CBCM) system is designed to track changes in, and status of, enterprise level programmatic operations. Enterprise decision making and operations rely on management of non-traditional configuration management (CM) components: estimates, agreements, goals, policies, strategies, plans, values, priorities, options, beliefs etc. Additionally, enterprise operations have unique environments/contexts: reviews, workshops, firedrills, OMB and Congressional actions, procurements, demos, experiments, etc. The CBCM system will unify off-the-shelf decision history and decision map systems to commercial configuration management systems. Significant knowledge management (KM) enhancements can be made to both the mapping frameworks, as front ends to the CM system, as well adding intelligence to the CM components to improve enterprise level assessments and forecasting. Specific CM objects will be customized to handle both the unique configurable enterprise components as well as the unique enterprise contexts. The KM enhancements focus on collaborative decision/history map development including multi-level independent forward and backward linking between large numbers of independent CBCM systems via the Web. This Web-based inter-activity will allow significant and unobtrusive communications and context enhancements to provide more extensive individual and organizational inputs/comments to a given enterprise strategic decision making activity. Finally, adaptive middleware technologies need to be integrated with the system so that decision/configuration changes can easily inter-operate with a range of enterprise level management systems (portfolio, budget, reporting, scheduling, etc.).

Other related areas of application of the CBCM system include risk management, schedule management, budgeting program/project management and configuration management.

A user interacts with a CBCM system through a graphical user interface, (GUI) with symbols representing different types or classes of decision objects that are placed on parallel time lines and are linked to show inter-dependencies between these objects. Information about a decision object (metadata) is entered and/or displayed by clicking on the corresponding symbol. All information is stored in an object-relational database that can be queried to provide information or to generate a report.

CBCM converts a graphic object, for example, as shown in any of FIGS. 5A-5J, 6A-6V and/or 7A-7F and associated metadata into extended markup language (XML) for storage, export, report generation and other tasks from a database. The database stores an associated time value for the decision object, any connections between decision objects, and all associated metadata.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 schematically illustrates a system architecture according to one embodiment of the invention.

FIGS. 2A-2B illustrate one embodiment of a CBCM GUI with an exemplary symbol library (FIG. 2A).

FIGS. 3A-3E illustrate icons and icon shapes for different classes of objects used in the invention.

FIGS. 4A, 4B and 4C display metadata associated with the icons in FIGS. 3A, 3B and 3C, respectively.

FIGS. 5A-5J are a sample set of 8 symbols used to refer to events in the GUI in FIG. 1.

FIGS. 6A-6V are a sample set of 11 decision object configuration or format symbols that may be used in a second layer of a FIG. 2A decision.

FIGS. 7A-7F are a sample set of decision object feedback and communication descriptors useful in providing feedback.

FIG. 8 illustrates establishment of connections between a set of six objects.

FIG. 9 illustrates map embedding, with three levels of object association.

FIG. 10 schematically illustrates operation of the system according to one embodiment.

DESCRIPTION OF BEST MODES OF THE INVENTION

FIG. 1 schematically illustrates architecture of a context based configuration management (CBCM) system 11, including: a configuration management (CM) sub-system 12
for standard CM workflow capabilities; an intelligent middleware (IM) sub-system for standard documentation management; a library of preconfigured artifact models and flexible interfaces; a decision history and map sub-system, used to capture and archive the full context for a decision environment; and a database sub-system providing multidimensional databases. The CM and IM sub-systems preferably rely upon anNX system, developed earlier by some of the inventors and issued as U.S. Pat. No. 6,968,338. The configuration management system includes relevant information on the history to date of changes in one or more of the maps, the change-initiator, etc., for each preceding version of a map.

FIG. 2A illustrates one embodiment of a graphical user interface (GUI) showing some of the key features that can be used to practice the invention. These features include specification of a context-based or content-based search, specification of data to be imported, a (first layer) symbol library for decision objects available for drag/drop onto a user-defined time line. A time line increment navigation control, a connector line segment or curve to associate two or more decision objects, an image zoom control, a general display area for the symbols explicitly shown, and a menu of generic computer operations. A time line having a first dimension is set forth in a first (horizontal) direction on the display area. A second dimension of the time line is defined in a second direction (e.g., approximately vertical) that is laterally oriented relative to the first direction in the display area. Where two or more decision objects are associated with each other, as where a first decision object must precede or occur at the same time as a second decision object, a line or connector is provided connecting these two or more decision objects, and these decision objects are said to “have a time relationship to each other.” Optionally, a vertically oriented connector indicates simultaneous occurrence; and a lateral, but not vertical, connector orientation indicates that the first decision object precedes the second decision object, as illustrated in FIG. 2A.

One or more icons can be added to, removed from, or merged with, another icon shown in the symbol library. This includes the icons from the classes of event objects, configuration objects and feedback/communication objects, shown in FIGS. 3A, 3B and 3C, respectively. Each of the icon classes is indicated on the screen in FIG. 2A by a distinguishable geometric shape, such as the triangle, quadrilateral and oval used for the icons in the classes shown in FIGS. 3A, 3B and 3C. The particular shapes used are not critical, as long as the shapes are distinguishable for each class. For example, a shape combining linear and curvilinear segments, such as the “sunrise” shape and the curvilinear trapezoid shown in FIGS. 3D and 3E, could also be used here.

The decision event icon, shown in FIG. 3A, preferably includes the event name, a mnemonic graphic element identifying the specific event, a connector region, used to link an icon to other icons, and the characteristic icon shape. The configuration icon, shown in FIG. 3B, includes the configuration name, a mnemonic graphic element identifying the specific configuration, a connector region and the characteristic icon shape. The feedback or communication icon, shown in FIG. 3C, includes the feedback mechanism name, a mnemonic graphic element, a connector region and the characteristic icon shape. Other relevant information can be included in an icon, as needed.

Icons from different classes may be introduced onto the screen in FIG. 2A, where, for example, icons from the decision events class (FIGS. 5A-5I) and from the configuration format (FIGS. 6A-6V) appear on the same screen.

A CBCM system is opened via a URL in a Web browser. Each CBCM decision map is stored as a document within a file system. To activate a decision process within the system, a user clicks on one or more icons from the symbol library to an appropriate time frame in the display and optionally provides one or more time line connections to this icon. Two or more decision objects are connected or linked by left clicking on the icon connector region and dragging a first object icon to contact a second object icon connector region on a screen. A right mouse click causes a pop-up in properties that can be used to activate or display additional information about the chosen decision object. Control buttons (e.g., 25, 27) located at the bottom of the GUI allow time line navigation, zoom, pan and other operations in the large.

Optionally, the GUI provided by the invention works with a first (overview) screen layer, shown in FIG. 2A, and a second (menu) screen layer, with one layer being presented at a time. FIGS. 4A, 4B and 4C illustrate menu layers for the decision events class, the configuration class and the feedback mechanism class that are illustrated in more detail in the respective FIGS. 5A-5I, 6A-6V and 7A-7F, discussed in the following. Within a given class, all menu formats are the same, although the metadata that appears in each entry of a menu may be different from one icon to another within that class.

FIG. 4A illustrates a decision event metadata display, which is brought up on a screen by left clicking and holding a selected icon from the class of icons shown in FIGS. 5A-5I. All decision event icons have a characteristic triangular shape, as shown in FIG. 3A. The decision event metadata includes: object type or class; event time and date; and last modified; icon author(s); phone number and e-mail address for contact of one or more of icon author(s); a change log for the icon and the associated information change; one or more user reference links; location(s) of the event; persons responsible for the decision; rationale references for this event; links from elsewhere to this object; feedback links; and link statistics.

FIG. 4B illustrates a configuration metadata display, which includes object type or class, time and date of creation and of last modification of configuration; summary of config.; config. author(s); phone number and e-mail address for contact of one or more of the authors; subscribers; user’s comments on config.; recommended action on config. and rationale; options for routing a config.; description of present version of the config.;

FIG. 4C illustrates a feedback mechanism and communication metadata display, which includes object type or class; time and date of event; date and time the feedback event was created and was last modified; icon author(s); phone number and e-mail address for contact of one or more authors; subscribers; user comments; feedback target(s); recommended feedback actions and rationales; options for routing a feedback communication; feedback links and link statistics; and parent and child links.

The system also provides one or more sub-map layers, as indicated in FIG. 9, that provide additional properties or user-entered information. A sub-map layer icon is part of the icon library and can be activated by dragging and dropping the sub-map layer icon onto the display screen in FIG. 2A. This will bring up a blank display screen, illustrated in FIG. 2B, that resembles the screen in FIG. 2A. The user then creates icons and other symbols representing information on the screen in FIG. 2B, in one or more sub-map layers.
Optionally, one or more of the icon menu layers has access control associated therewith that restricts access through the usual permissions (view, read, write, delete, edit, etc.), based upon the user's authenticated identity. For example, the menu layer of the "Re-Orgs" icon may be available for viewing by any user, but a second menu layer, such as "Demonstrations," may not allow viewing without presentation of access permission by the user.

FIGS. 5A-5J illustrate N1(±2) of the decision events (actions that occur at a specific point in time), with N1=10 here. With reference to FIG. 5A, a "decision" can be a formal, explicit and final decision on an issue. Alternatively, the decision can be implicit or expected, one that has not yet been finalized but already has produced an impact on one or more activities of the organization. Optionally, real and apparent (not yet explicitly implemented) decisions can be captured here.

With reference to FIG. 5B, a "demonstration" is normally a significant event, such as a test flight, demo. of a new system, etc. that is intended to illustrate the capabilities of a major program or project. A demonstration may be a precursor to one or more new decisions to be made, based on the success or failure of the demonstration.

With reference to FIG. 5C, a "fire drill" is typically an unplanned and time-constrained activity that results from an unexpected decision or event. A fire drill may be captured as an exception to a planned activity and may have major consequences.

With reference to FIG. 5D, a "generic" decision object is left uncharacterized at this time.

With reference to FIG. 5E, a "lesson learned" represents the outcome(s) of an activity, for example, the CAIB Report on investigation of the circumstances surrounding the Columbia Space Shuttle disaster. A lesson learned may be captured in a specific report or set of data and may heavily influence one or more subsequent decisions.

With reference to FIG. 5F, a "re-organization" is a change to an organizational structure and may be planned or unplanned.

With reference to FIG. 5G, a "review" typically precedes one or more decisions that generate a new activity or one or more changes to a plan or a re-organization. A review is typically a precursor to a decision and may generate one or more subsequent reviews.

With reference to FIG. 5H, a "workshop" is an activity or event performed to integrate an inter-disciplinary team to achieve a specific, short-term objective, for example, generating a new proposal.

With reference to FIG. 5I, a "selection" or "procurement" is an event, such as a request for a bid or quote or proposed design based on specifications supplied by a requester, and/or a selection of one or more successful bidders or designers for a project.

With reference to FIG. 5J, an "initiation" or "deployment" is an initial use of a design or technology or procedure that has been accepted, with a view to testing of, or field use of, the design or technology or procedure.

Information concerning an event (metadata) is captured and stored in a database and is accessible through specified search or report queries. An event property is entered by a user and may include one or more of the following fields: characterization of the event; leader or coordinator; leader affiliation; date of event; point of contact for event; consequences, if any, of event.

FIGS. 6A-6V illustrate N2(±2) configurations or formats for decision object, which are tracked for status, with N1=22 here. With reference to FIG. 6A, a "budget" concerns funding available for a particular program for a particular time interval.

With reference to FIG. 6B, an "agreement" or "contract" is a formal/informal agreement between two or more entities that defines the terms and conditions for qualification, performance and/or performance mode(s), including delivery of work product.

With reference to FIG. 6C, a "document" (real or virtual) contains or presents information relevant to a decision or activity. The document can be physical (e.g., captured on paper or another tangible medium), or electronic and can refer to other forms of information available within the system.

With reference to FIG. 6D, a "metric" is a quantitative measurement applied to a specific objective, program or other activity. Often, a metric is associated with a scale or other mechanism for comparison with other similar measurements.

With reference to FIG. 6E, an "organization" refers to a combination of human resources associated with a program or activity. An organization can be hierarchical, matrix or virtual, among other characteristics.

With reference to FIG. 6F, a "policy" defines which rules apply to a particular decision or activity. As an example, a policy may have substantial impact on budget allocations for a particular program.

With reference to FIG. 6G, a "requirement" can be explicit (documented) or implicit (informal) and is applied to one or more associated activities.

With reference to FIG. 6H, a "risk" may be anything having potential negative impact on an activity or program. A risk may be standard, expected, or unusual (unique to a particular activity or program).

With reference to FIG. 6I, a "model or simulation parameter" is a relevant parameter used in achieving a simulation result that may appear as data in a simulation result of FIG. 6J.

With reference to FIG. 6J, a "simulation result" is data, generated in other than an actual setting, that can be used to predict a probable future outcome of an activity or program.

With reference to FIG. 6K, a "strategy or plan" is a formal document used to plan and manage and evaluate a program or activity. Alternatively, the strategy or plan can be verbal or virtual.

With reference to FIG. 6L, a "value" is a subjective definition or metric that provides a guide to treatment of one or more persons involved with a program or activity.

With reference to FIG. 6M, a "goal" is an aim or purpose, to be formally achieved, as evaluated by one or more metrics (FIG. 4D).

With reference to FIG. 6N, a "procedure" is a reasonably detailed sequence of steps or processes that can be used to achieve (part of) a goal.

With reference to FIG. 6O, a "roadmap" is an array of major steps or processes, together with one or more metrics, to be used to evaluate how far a project has developed at a particular time.

With reference to FIG. 6P, a "milestone" or "schedule" is an array or timeline containing one or more date/time combinations at which a selected fraction of a project is expected to be completed. A milestone may include one or more metrics (FIG. 6D).

With reference to FIG. 6Q, an "estimate" provides an estimate of time schedule and/or cost and/or performance measure for a project.

With reference to FIG. 6R, an "option" includes at least one alternative approach to implementing one or more of the procedural steps of FIG. 6N.
With reference to FIG. 6S, a “mitigation” is an alternative or additional procedural step that may be taken to lessen the impact(s) or the cost(s) or the scheduling constraint(s) associated with a project.

With reference to FIG. 6T, “facilities” refers to equipment, tools, real estate and related physical, non-personnel assets available to be used, or allocated, for a project.

With reference to FIG. 6U, “personnel” refers to specific persons, and associated talents, to be used for a project.

With reference to FIG. 6V, “portfolios” refers to non-physical and non-personnel assets available to be used for a project.

A mission statement for an organization or program will typically set forth values intended to govern or modify behavior of one or more persons in an organization.

FIGS. 7A-7F are N3 descriptors, with N3=6 here, which provide mechanisms for feedback or connections to decisions and decision processes. A user can link a note or question or belief/assumption to a decision or a configuration item to provide feedback or connections to decisions and/or decisions associated with the project; and a tenth icon representing a lesson learned” that is associated with the project; a sixth icon representing a fire drill activity associated with the project; a fourth icon representing a generic activity associated with the project; a fifth icon representing an unresolved, or not fully recognized, issue associated with an approach to a project; or to one or more warnings or cautionary notes concerning an approach to a project.

With reference to FIG. 7G, a “disconnect” is an inconsistent or incomplete feature associated with an approach to a project. A graphical connector between two or more objects represents an association or dependency. In most or all instances, a connection between a first object and a second object that is positioned above and/or to the right of the first object on the screen indicates that information that is made available by the first object (e.g., as an output) is received by and used by the second object. A connector is created by dragging a mouse from the center of the first object to a center of the second object; the connection indicates that information usually flows toward the right and/or toward the top, although two-way communication is permitted.

A single decision map can be embedded within another decision map, usually in a hierarchical manner. No limit is imposed on the number of levels of maps that can be created. FIG. 9 illustrates creation of a particular set of connections between six objects.

A single decision map can be embedded within another decision map, usually in a hierarchical manner. No limit is imposed on the number of levels of maps that can be created. A sub-map (embedded in another map) is preferably shown with a contrasting color and/or texture from the “parent” map.

FIG. 9 illustrates an example with three levels of sub-layer embedding. The map proceeds from a root node (“Main map (0)”) to two first level sub-maps, (1) and (2). The first level sub-map (1) is connected to a second level sub-map (1,1); and the second first level sub-map (2) is connected to first and second, second level sub-maps, (2,1) and (2,2). Additional second level and lower level sub-maps can be included and connected, if needed. The configuration in FIG. 9 may represent an inquiry, in which the root node is an initial activity or event and the lower level sub-maps correspond to subsequent events and/or subsidiary descriptors that are interpreted in a context associated with the root node. Access control and security are optionally imposed on viewing, reading, writing, editing, deleting, etc. for each level of sub-layer maps.

FIG. 10 schematically illustrates operation of one embodiment of the system 101. The user is presented with a browser 102, which optionally uses either flash or Javascript to translate user requests into commands that are received by a database 103. The database 103 may rely upon any of several context-based and/or content-based query systems, such as NX, Netmark, etc. and upon http basic commands (get, put, post, etc.). The database 100 presents and allows manipulation of various GUI configurations and features 104, such as icons, fields, field types, variable types, etc., and presents and allows manipulation of user-defined maps 105, such as the map presented in FIG. 2A.

Security and access control, if activated, are implemented first at the browser level, which requires presentation of an authenticated user identity (password, biometric indicium, signature, etc.). The authenticated user identity is then received by a security module 106, associated with the database 103, which analyzes the user identity and sets appropriate access controls and permissions associated with the user maps (FIGS. 2A, 2B), with decision events (FIGS. 5A-5I), with formats for decision objects (FIGS. 6a-6v), with decision object descriptors (FIGS. 7A-7F), and with the associated under-layers for the different icons.

What is claimed is:

1. A method for configuring and displaying information on a computer:

   to provide and display a first collection of N1 visually perceptible and distinguishable event icons representing N1 different activities, numbered n=1, . . . , N1 (N1≧2), associated with a project, where the first collection comprises N1 icons from a group including: a first icon representing a decision made or to be made, concerning the project; a second icon representing a demonstration associated with the project; a third icon representing a fire drill activity associated with the project; a fourth icon representing a generic activity associated with the project; a fifth icon representing at least one “lesson learned” that is associated with the project; a sixth icon representing a reorganization activity associated with the project; a seventh icon representing a review activity associated with the project; an eighth icon representing a workshop activity associated with the project; a ninth icon representing a procurement/selection activity associated with the project; and a tenth icon representing initiation or deployment of at least a portion of the project;

   to provide a time line, having at least a first dimension and a second laterally oriented dimension, and associating first and second event icons, with selected time values, t=t1, and t=t2, respectively, along the time line, with t1≧t2;

   to provide a connector line, oriented lateral to the first dimension, connecting the first and second event icons, when the first and second event icons have a time relationship relative to each other;

   to provide a visually perceptible display of the time line and of the first and second decision icons and the connector line at a selected location along the time line;

   to provide mechanisms for feedback or connections to decisions and/or associated with the project; and a tenth icon representing a lesson learned” that is associated with the project; a sixth icon representing a fire drill activity associated with the project; a fourth icon representing a generic activity associated with the project; a fifth icon representing at least one “lesson learned” that is associated with the project; a sixth icon representing a reorganization activity associated with the project; a seventh icon representing a review activity associated with the project; an eighth icon representing a workshop activity associated with the project; a ninth icon representing a procurement/selection activity associated with the project; and a tenth icon representing initiation or deployment of at least a portion of the project;
to provide a second collection of N2 visually perceptible icons representing N2 configurations numbered n2=1\ldots N2 (N2≥2), associated with the project where the second collection comprises N2 icons from a group including: a first icon of the second collection representing a budget for at least a portion of the project; a second icon of the second collection representing an agreement or contract associated with the project; a third icon of the second collection representing a collection of at least one document associated with the project; a fourth icon of the second collection representing a metric associated with the project; a fifth icon of the second collection representing an organization associated with the project; a sixth icon of the second collection representing a policy associated with the project; a seventh icon of the second collection representing one or more requirements associated with the project; an eighth icon of the second collection representing at least one risk associated with the project; a ninth icon of the second collection representing at least one model or simulation parameter or associated with the project; a tenth icon of the second collection representing at least one result or prediction of a simulation associated with the project; an eleventh icon of the second collection of the second collection representing at least one strategy or plan associated with the project; a twelfth icon of the second collection representing at least one value associated with the project; a thirteenth icon of the second collection representing a collection of at least one model or simulation parameter or associated with the project; an eighteenth icon of the second collection representing at least one milestone or schedule associated with the project; an eighteenth icon of the second collection representing at least one option associated with the project; a nineteenth icon of the second collection representing at least one configuration associated with the selected icon, where the metadata information further includes: at least one of time and date associated with at least one event; time and date the selected icon was created and was last modified; author(s) of the selected icon; at least one of phone number and e-mail address for contact of one or more authors of the selected icon; a change log for the selected icon and the associated information change; one or more user reference links; location(s) of the at least one event; at least one person responsible for the at least one event; rationale for the at least one event; links from at least one other location to the selected icon; feedback links; and link statistics.

3. The method of claim 2, further comprising programming said computer:

to provide, upon receipt of an event metadata activation signal associated with a selected event icon from among said N1 event icons, metadata information in a visually perceptible format in an under-layer associated with the selected event icon, on at least one event associated with the selected icon, including information on history of events associated with the selected icon, where the metadata information further includes: at least one of time and date associated with at least one event; and at least one of phone number and e-mail address for contact of one or more authors of the selected icon; a change log for the selected icon and the associated information change; one or more user reference links; location(s) of the at least one event; links from at least one other location to the selected icon; feedback links; and link statistics.

4. The method of claim 1, further comprising programming said computer:

to provide a visually perceptible display of the third connector line and of the third decision icon and the third configuration icon, at a third selected location along the time line.

5. The method of claim 4, further comprising programming said computer:

to provide a visually perceptible display of the third connector line and of the third decision icon and the third configuration icon, at a third selected location along the time line.

6. The method of claim 1, further comprising programming said computer:

to provide a third collection of N3 visually perceptible icons representing N3 feedback mechanisms associated with decision processes, numbered n3=1\ldots N3 (N3≥2), where the third collection comprises N3 icons from a group including: a first note/tag icon from the third collection representing at least one unresolved question associated with said project; a second question icon of the third collection representing at least one
portfolio asset associated with said project; a third icon of the third collection representing at least one unresolved question associated with said project; a fourth waste/inefficiency icon of the third collection representing at least one wasteful or inefficient procedure associated with said project; a fifth issue/warning icon of the third collection representing at least one dangerous procedure associated with said project; a sixth disconnect icon of the third collection representing at least one disconnect or inconsistent response associated with said project;

to associate first and second feedback icons, with selected time values, \( t_{15} \) and \( t_{16} \), respectively, along said time line, with \( t_{15} \leq t_{16} \);

to provide a second connector line, oriented lateral to said first dimension, connecting the first and second feedback icons, when the first and second feedback icons have a time relationship relative to each other;

to provide a visually perceptible display of the second connector line and of the first and second feedback icons, at a second selected location along said time line;

to associate a third event icon and a third configuration icon, with selected time values, \( t_{17} \) and \( t_{18} \), respectively, along said time line, and to provide a third connector line, oriented lateral to said first dimension, connecting the third event icon and the third configuration icon, when the third event icon and the third configuration icon have a time relationship relative to each other; and

to provide a visually perceptible display of the third connector line and of the third event icon and the third configuration icon, at a third selected location along said time line;

to associate a fourth event icon and a fourth feedback icon, with selected time values, \( t_{19} \) and \( t_{20} \), respectively, along said time line, and to provide a fourth connector line, oriented lateral to said first dimension, connecting the fourth event icon and the fourth feedback icon, when the fourth event icon and the fourth feedback icon have a time relationship relative to each other;

to provide a visually perceptible display of the fourth connector line and of the fourth event icon and the fourth feedback icon, at a fourth selected location along said time line;

to associate a fifth configuration icon and a fifth feedback icon, with selected time values, \( t_{12,1} \) and \( t_{12,2} \), respectively, along said time line, and to provide a fifth connector line, oriented lateral to said first dimension, connecting the fifth configuration icon and the fifth feedback icon, when the fifth configuration icon and the fifth feedback icon have a time relationship relative to each other; and

to provide a visually perceptible display of the fifth connector line and of the fifth configuration icon and the fifth feedback icon, at a fifth selected location along said time line.

7. The method of claim 6, further comprising programming said computer:

to provide, upon receipt of a feedback metadata activation signal associated with a selected feedback icon from among said \( N_3 \) feedback icons, feedback metadata information in a visually perceptible format in an under-layer associated with the selected feedback icon, on feedback associated with the selected icon, including information on history of feedback associated with the selected icon, where the metadata information includes at least one of: object type or class; time and date of feedback event; date and time the feedback event icon was created and was last modified; icon author(s); phone number and e-mail address for contact of one or more authors; subscribers; user comments; feedback target(s); recommended feedback actions and rationales; options for routing a feedback communication; feedback links and link statistics; and parent and child links.

8. The method of claim 7, further comprising programming said computer:

to receive access control information on a user of said computer and to restrict or preclude user activity in at least one of viewing, reading, writing, deleting and editing of said selected icon under-layer.
