ABSTRACT

The NASA project to develop In-Situ Resource Utilization (ISRU) technologies, in partnership with commercial and international collaborators, has achieved full system demonstrations of oxygen production using native regolith simulants. These demonstrations included robotic extraction of material from the terrain, sealed encapsulation of material in a pressurized reactor, chemical extraction of oxygen from the material in the form of water, and the electrolysis of water into oxygen and hydrogen for storage and reuse. These successes have provided growing confidence in the prospects of ISRU oxygen production as a credible source for critical mission consumables in preparation for and during crewed missions to the moon and other destinations. Other ISRU processes, especially relevant to early lunar exploration scenarios, have also been shown to be practical, including the extraction of subsurface volatiles, especially water, and the thermal processing of surface materials for civil engineering uses and for thermal energy storage. This paper describes these recent achievements and current NASA ISRU development and demonstration activity. The ability to extract and process resources at the site of exploration into useful products such as propellants, life support and power system consumables, and radiation and rocket exhaust plume debris shielding, known as In-Situ Resource Utilization or ISRU, has the potential to significantly reduce the launch mass, risk, and cost of robotic and human exploration of space. The incorporation of ISRU into missions can also significantly influence technology selection and system development in other areas such as power, life support, and propulsion. For example, the ability to extract or produce large amounts of oxygen and/or water in-situ could minimize the need to completely close life support air and water processing system cycles, change thermal and radiation protection of habitats, and influence propellant selection for ascent vehicles and surface propulsive hoppers. While concepts and even laboratory work on evaluating and developing ISRU techniques such as oxygen extraction from lunar regolith have been going on since before the Apollo 11 Moon landing, no ISRU system has ever flown in space, and only recently have ISRU technologies been developed at a scale and at a system level that is relevant to actual robotic and human mission applications. Because ISRU hardware and systems have never been demonstrated or utilized before on robotic or human missions, architecture and mission planners and surface system hardware developers are hesitant to rely on ISRU products and services that are critical to mission and system implementation success. To build confidence in ISRU systems for future missions and assess how ISRU systems can best influence and integrate with other surface system elements, NASA, with international partners, are performing analog field tests to understand how to take advantage of ISRU capabilities and benefits with the minimum of risk associated with introducing this game-changing approach to exploration. This paper will describe and review the results of four analog field tests (Moses Lake in 6/08, Mauna Kea in 11/08, Flagstaff in 9/09, and Mauna Kea in 1/10) that have begun the process of integrating ISRU into robotic and human exploration systems and missions, and propose future ISRU-related analog field test activities that can be performed in collaboration with international space agencies.
Integration of ISRU into Lunar/Mars Exploration Through Field Analogs

Presentation to COSPAR 2010
Bremen Germany, July 19, 2010

What is In-Situ Resource Utilization (ISRU)?

ISRU involves any hardware or operation that harnesses and utilizes ‘in-situ’ resources (natural & discarded) to create products and services for robotic and human exploration.

Five Major Areas of ISRU

- **Resource Characterization and Mapping**
  Physical, mineral/chemical, and volatile/water

- **Mission Consumable Production**
  Propellants, life support gases, fuel cell reactants, etc.

- **Civil Engineering & Surface Construction**
  Radiation shields, landing pads, roads, habitats, etc.

- **In-Situ Energy Generation, Storage & Transfer**
  Solar, electrical, thermal, chemical

- **In-Situ Manufacturing & Repair**
  Spare parts, wires, trusses, integrated structures, etc.

- ‘ISRU’ is a capability involving multiple technical discipline elements (mobility, regolith manipulation, regolith processing, reagent processing, product storage & delivery, power, manufacturing, etc.)

- ‘ISRU’ does not exist on its own. By definition it must connect and tie to multiple uses and systems to produce the desired capabilities and products.
ISRU: Critical for Affordable, Flexible, & Sustainable Exploration

Propellant Production
- Reduces Earth to orbit mass by 20 to 45% for Mars missions
- 3.5:1 to 5:1 mass savings leverage from Moon/Mars surface back to Low Earth Orbit

Risk Reduction & Flexibility
- Number of launches & mission operations reduced
- Use of common hardware & mission consumables enables increased flexibility
- In-situ fabrication of spare parts enables sustainability and self-sufficiency
- ISRU can provide dissimilar redundancy
- Radiation & Plume Shielding
- Reduces dependence on Earth

Space Resource Utilization
- Develops alternative & renewable energy technologies
- CO₂ remediation
- Green metal production

Expands Human Presence
- Increase Surface Mobility & extends missions
- Habitat & infrastructure construction
- Propellants, life support, power, etc.
- Substitutes sustainable infrastructure cargo for propellant & consumable mass

Solves Terrestrial Challenges & Enables Space Commercialization
- Provides infrastructure to support space commercialization
- Propellant/consumable depots at Earth-Moon L1 & Surface for Human exploration & commercial activities

Mass Reduction
- Reduces number and size of Earth launch vehicles
- Allows reuse of transportation assets
- Minimizes development costs

Cost Reduction
- In-situ fabrication of spare parts enables sustainability and self-sufficiency
- ISRU can provide dissimilar redundancy
- Radiation & Plume Shielding
- Reduces dependence on Earth

G. Sanders/JSC, gerald.b.sanders@nasa.gov
Key Architecture Decisions That Impact ISRU

- **Is Abort-to-Surface (vs Abort-to-Orbit) a Viable Option? If yes:**
  - Ascent propellant production and transfer to increase payload to surface is possible

- **Is Reusable Transportation (even one reuse) a Long-term Objective? If yes:**
  - Landing/ascent pads and surface propellant depots
  - Large scale propellant production
    - If O₂/H₂ propellants -> Need polar water or H₂ delivery from Earth
    - If O₂/CH₄ propellants -> Need O₂ from regolith and CH₄ from trash/waste/plants or CH₄ delivery from Earth
  - Propellant depots in LLO or L₁
  - Surface hopping to other locations (and back)

- **How Much Radiation Shielding is Adequate for Crew Protection?**
  - Propellant scavenging for water/hydrogen
  - Habitat burial or regolith shielding of habitats
  - Trash processing for radiation shielding

- **What is the approach for eclipse/night survival and operation?**
  - Increased fuel cell reactant storage
  - Thermal storage with in-situ materials (‘wadis’)

- **Is Mars Forward the Primary Goal for Lunar Exploration?**
  - Demonstrate Mars applicable technologies, systems, and applications
  - Demonstrate remote/uncrewed and long-duration operations

- **Is Space Commercialization and Long-term Settlement of the Moon a Goal?**
  - In-situ fabrication, construction, power, and consumables by commercial provider
ISRU Connectivity with Other Exploration Elements Strongly Influences Designs

Construction & Manufacturing
- Hydrocarbons for plastics
- Materials for concrete & metal structures
- Gas for pneumatic systems
- Explosives

CFM technology common with ISRU

Lander/Ascent Propulsion
- Propellant (O₂ or O₂/fuel)
- Purge gas/tank pressurant
- Residual Propellants

Surface Mobility
- Defines resource excavation & transportation capabilities
- Fuel cell, water processing, & CFM technologies common with ISRU

Environmental Control & Life Support System (ECLSS)
- O₂, H₂O and N₂/Ar for Habitat & EVA suits
- CO₂ for dust cleaning
- Water and carbon waste from ECLSS

ECLSS technology common with ISRU

Thermal Energy

Resource Utilization (ISRU)

Resource instruments

Subsurface access

Gases for science instruments and cleaning

Fuel cell reagents (O₂ and fuel)

Water from fuel cell

Extra Vehicular Activity (EVA)
- Defines surface power needs and fuel cell reagents

Surface & Fuel Cell Power Generation

Science Activities

Defines level of closed-loop ECLSS required

Explosives

Materials for concrete & metal structures

Gases for pneumatic systems

Hydrocarbons for plastics

CO₂ for dust cleaning

Water and carbon waste from ECLSS

Defines propellant options & propulsion capabilities

Extra Vehicular Activity (EVA)
Maximize benefit of using resources, in the shortest amount of time, while minimizing crew involvement and Earth delivered infrastructure

- **Resource knowledge**
  - Characterization of form and spatial distribution of resources to degree necessary to plan use of ISRU at possible sites of exploration

- **Operation in severe environments**
  - Operation and interaction with dust
  - Efficient excavation of resources in extremely cold, vacuum, and/or micro-g environments
  - Startup/shutdown cycles during day/night
  - Methods to mitigate dust/filtration for Mars atmospheric processing

- **Long-duration, remote and autonomous operation**
  - Autonomous control & failure recovery
  - Long-duration operation (>300 days for Mars; 3 years for lunar)

- **High reliability and minimum (zero) maintenance**
  - High reliability due to no (or minimal) maintenance capability for pre-deployed and robotic mission applications
  - Failure mitigation approach
  - Development of highly reliable thermal/mechanical cycle units
  - Development of highly reliable, autonomous calibration control hardware and sensors

- **Integrated fluids and operations with other Elements**
  - Interfaces and standards
  - Common fluids and hardware
ISRU incorporated into human exploration missions is a conundrum

- Learning to use the resources at the site of exploration (ISRU) to reduce cost and risk is considered an important part of why we are exploring space.
- However, since ISRU has never been flown/demonstrated, mission planners do not want to rely on ISRU for mission success.
- Architectures and elements that do not rely on ISRU are designed differently and benefits downstream are greatly reduced (ex. ELS and Lander Propulsion).
- Therefore, ISRU is not ‘Critical’ for the architecture and implementation is delayed, BUT . . .

| Early ISRU Validation Thru Precursors | Earlier ISRU Incorporation and Use in Missions | Greater cost & risk reduction; Earlier Sustainability |

Two possible approaches to break the “Catch 22” cycle

- Fly ISRU demonstrations on robotic precursor missions to validate environmental compatibility and performance capability.
- Perform integrated ground tests of ISRU with linked surface and transportation systems to validate interfaces and product availability and quality.
Why Perform Analog Field Tests?

Concrete Benefits of Field/Analog Testing
- Mature Technology
- Evaluate Mission Architecture Concepts Under Applicable Conditions
- Evaluate Operations & Procedures
- Integrate and Test Hardware from Multiple Organizations
- Develop engineers and project managers

Intrinsic Benefits of Field/Analog Testing
- Develop International Partnerships
- Develop Teams and Trust Early
- Develop Data Exchange & Interactions with International Partners (ITAR)
- Outreach and Public Education

Pg. 9
Early Surface Preparation Field Evaluation

- **Mosses Lake, June 2008**: LANCE Blade mounted to “Chariot” mobile platform
  - 1st integrated field test of ISRU hardware on mobility platform for surface construction
  - No articulation capability on blade required mobile platform to perform all x-y-z actuations
  - Large area cleared and berm built via on-site, visual tele-operation
  - Blade interference with ground on rough terrain due to extension from front end

- **Flagstaff, Sept. 2009**: LANCE Blade mounted to “Chariot” & LER platforms
  - Z-axis articulation capability on blade allowed better ground clearance on rough terrain
  - Quick disconnect mechanism allowed for blade integration and removal for dedicated tests
  - Similar overall surface preparation performance
Field Test Mission Objectives

- **Field Dates:** Oct. 30 to Nov. 15, 2008
  Mauna Kea, Hawaii

- **Mission Key Personnel**
  - Jerry Sanders & Bill Larson, ISRU PM
  - Tom Simon/OPTIMA lead
  - Frank Schowengert, PISCES
  - Rob Ambrose HRS PM & John Caruso
  - Jackie Quinn/RESOLVE lead
  - Michel Doyon, CSA

- **Need for ISRU Field Test**
  - Hardware from the ISRU Project needed to move from the laboratory to more challenging conditions
  - ISRU Hardware had never operated in an end-to-end system before or had been field tested

- **NASA Hardware-Operation Objectives**
  1. **ISRU Mobile Resource Prospecting & Oxygen Production Demo Field Test:** Test resource prospecting, site survey, and oxygen production activities while integrated onto a mobile platform
  2. **ISRU End-to End Outpost Scale Oxygen Production & Storage Field Test (OPTIMA):** Demonstrated excavation, regolith delivery, regolith processing, and oxygen production and storage
  3. **Demonstrate partnership with State of Hawaii and Pacific International Space Center for Exploration Systems (PISCES):** Have PISCES ‘host’ field test activity by providing support, logistics, and facilities

5 NASA Centers, 2 International Space Agencies, 7 Companies, & 2 Universities
ISRU Hardware Tested at Analog Site

**Lunar Prospecting**
- Scarab Rover
- RESOLVE
- TriDAR Vision System
- Tweels

**Outpost-Scale O$_2$ from Regolith**
- ROxygen H$_2$ Reduction
- Water Electrolysis
- Cratos Excavator

**Process Control & Science**
- PILOT H$_2$ Reduction
- Water Electrolysis
- Bucketdrum Excavator
- Moessbauer
- Mini Chemin XRD/XRF

**Canadian Space Agency**
- TriDAR imager, Satellite communications, remote operation of Drill and TriDAR navigation, and on-site personnel and payload mobility
- NORCAT, Xiphos, Argo, Virgin Technologies, EVC, Ontario Drive Gear, University of Toronto

**German Space Agency (DLR)**
- Instrumented “Mole” & Sample Capture Mole

**Carnegie Mellon University**
- SCARAB Rover

**JPL Partnership with Michelin on ‘Tweels’ testing**
Major Results From Nov. 2008 ISRU Analog Field Test

☑ Demonstrated end-to-end operation of RESOLVE/Scarab; roving over varied terrain, dark navigation, drill site selection; remote operation from CSA

☑ Demonstrated end-to-end PILOT & ROxygen operations: regolith delivery, reactor fill/empty, regolith processing, water capture and clean-up, oxygen production

☑ RESOLVE: 6 Drilling, 6 Volatile characterization; and 4 Oxygen extraction operations

☑ PILOT: 6 complete reactor operations; 1000 ml of water produced from iron-oxide

☑ ROxygen: 5 complete reactor operations (2 Argon/3 Hydrogen)

☑ 1st Successful field deployment of ISRU

☑ 1st field deployment with International Partner
Field Test Mission Objectives

- **Field Dates:** Jan. 24 - Feb. 14, 2010
- **Location:** Mauna Kea, Hawaii

**Mission Key Personnel**
- Jerry Sanders/Bill Larson/Janine Captain, ISRU
- Glen Bilodeau, CSA
- Frank Schowengardt/Bob Fox, PISCES
- Dale Boucher, NORCAT
- Lutz Richter, DLR

**NASA Hardware-Operation Objectives**
1. **O₂ Production from Regolith:** Test enhanced Oxygen extraction from regolith system & operations
2. **ISRU Product Storage & Utilization:** Test hardware, operations, and energy systems that promote product usage
3. **Lunar ISRU, Exploration, & Science Integration:** Integrate lunar exploration, resource & site evaluation, and lunar science objectives, instruments, and operations
4. **Site Preparation:** Test hardware, operations, and surface sintering techniques
5. **Field Geology Training:** Train astronauts, ISRU, and NASA/CSA management on geology

Major Results From Jan. 2010 ISRU Analog Field Test

- Extracted oxygen from local tephra (28 gms or 9.6% ave. yield) using advanced processing and regolith transfer hardware in end-to-end configuration
- Electrolyzed water from tephra and fuel cell, transferred oxygen to cryogenic cart for liquefaction, and performed 17 LO₂/CH₄ thruster firings; “Dust to Thrust”
- Sintered two surface pads with two different methods and performed thruster firings with high speed camera to understand plume effects on unmodified and modified surfaces
- Integrated NASA and CSA/Canadian hardware in multiple critical applications
- Operated RESOLVE remotely from KSC and Solar Collector, Carbothermal Reactor, and Water Electrolysis systems remotely from JSC
- Tested SMD FSAT and MMAMA instruments for site/mineral characterization and support oxygen extraction process evaluation
- Completed field geology training with NASA and CSA managers and a CSA astronaut
Potential Areas of Interest for Next Analog Test

Scout & Prepare for Human Mission

Scout Terrain & Resource → Cache Consumables with ISRU → Prepare Site & Power System → Crew Arrives

1a. Characterize & Map Polar Volatiles/Ice Resources
1b. Characterize & Map Terrain and Resources for Oxygen Extraction from Regolith and Site Preparation
2. Lunar O₂ Production Lander Demo (Create cache of O₂ for crew and power)
3. Prepare Site for Crewed Lander to Minimize Risk
4. Establish Power & Consumable Infrastructure before Crew Arrives

Backup
ISRU Enables Sustainable & Affordable Transportation & Surface Exploration

- 3.5:1 to >5:1 mass savings leverage from surface back to Low Earth Orbit
- >70% of LSAM mass is propellant
- >35% of landed payload mass is propellant for ascent vehicle

Oxygen, Water, & Propellant from Lunar ISRU

Lander & Hopper Propellant Resupply & Servicing for Reuse

Propellant Depot for:
- Lunar ascent/descent
- Trans-Earth Injection
- Other destinations

Earth-Moon Staging Point

Earth Orbit Operations

Lunar Surface

Surface Exploration

Common ISRU-provided consumables for Propulsion, EVA & Habitat Life Support, and EVA Suit & Rover Power

Shielding for Radiation & Dust/Plume Protection

- Reduces Earth launch mass and cost or increases payload delivery capability
- Maximizes ability to reuse transportation assets further reducing cost
- Minimizes risk due to functional backup and flexibility in recovering from failures
- Increased surface mobility and power-rich environment enables new science and exploration capabilities

G. Sanders/JSC, gerald.b.sanders@nasa.gov
Incorporation of ISRU can strongly effect requirements and hardware/technology options selected.

ISRU Insertion Approaches

- Evolve Sustainability - ISRU When Its Ready (current approach)
  - No reusable transportation elements at the start of the architecture
  - ISRU & propellant depots not in initial critical path to mission success
  - Demonstrate ISRU capabilities early
  - Design Architecture to incorporate ISRU products and services when adequately demonstrated

  **Low Risk but High Life Cycle Costs**

- Sustainability as Driver - ISRU From Start (this may be the new program)
  - Develop reusable transportation elements, propellant depots, and ISRU in critical path; human and cargo landers synergistic with Mars
  - Utilize Earth supplied propellants for depot until ISRU is fully demonstrated

  **Higher Upfront Costs & Delayed Human Exploration but more Sustainable**
