Injecting Errors for Testing Built-in Test Software

Lyndon B. Johnson Space Center, Houston, Texas

Two algorithms have been conceived to enable automated, thorough testing of Built-in test (BIT) software. The first algorithm applies to BIT routines that define pass/fail criteria based on values of data read from such hardware devices as memories, input ports, or registers. This algorithm simulates effects of errors in a device under test by (1) intercepting data from the device and (2) performing AND operations between the data and the data mask specific to the device. This operation yields values not expected by the BIT routine. This algorithm entails very small, permanent instrumentation of the software under test (SUT) for performing the AND operations.

The second algorithm applies to BIT programs that provide services to users’ application programs via commands or callable interfaces and requires a capability for test-driver software to read and write the memory used in execution of the SUT. This algorithm identifies all SUT code execution addresses where errors are to be injected, then temporarily replaces the code at those addresses with small test code sequences to inject latent severe errors, then determines whether, as desired, the SUT detects the errors and recovers.

Guidance and Control System for a Satellite Constellation

Goddard Space Flight Center, Greenbelt, Maryland

A distributed guidance and control algorithm was developed for a constellation of satellites. The system repositions satellites as required, regulates satellites to desired orbits, and prevents collisions.

1. Optimal methods are used to compute nominal transfers from orbit to orbit.
2. Satellites are regulated to maintain the desired orbits once the transfers are complete.
3. A simulator is used to predict potential collisions or near-misses.
4. Each satellite computes perturbations to its controls so as to increase any unacceptable distances of nearest approach to other objects.
5. Once all danger is passed, the satellites return to their original orbits, all the while avoiding each other as above.
6. The delta-Vs are reasonable. The controller begins maneuvers as soon as practical to minimize delta-V.
7. Despite the inclusion of trajectory simulations within the control loop, the algorithm is sufficiently fast for available satellite computer hardware.

8. The required measurement accuracies are within the capabilities of modern inertial measurement devices and modern positioning devices.

This work was done by Gregory Aist and James Hieronymus of the Research Institute for Advanced Computer Science, John Dowding and Beth Ann Huch of the University of California, Santa Cruz; Manny Rayner of the International Computer Science Institute; Nikos Chatzichrisafis of the University of Geneva; Kim Farrell of QSS; and Jean-Michel Renders of Xerox Research Center Europe for Ames Research Center.
