An InGaP heterojunction barrier solar cell consists of a single, ultra-wide GaAs, aluminum-gallium-arsenide (AlGaAs), or lower-energy-gap InGaP absorber well placed within the depletion region of an otherwise wide bandgap PIN diode. Photogenerated electron collection is un-cumbered in this structure. InGaAs wells can be added to the thick GaAs absorber layer to capture lower-energy photons.

Determining Shear Stress Distribution in a Laminate

A “simplified shear solution” method approximates the through-thickness shear stress distribution within a composite laminate based on an extension of lamina нем beam theory. The method does not consider the solution of a particular boundary value problem; rather, it requires only knowledge of the global shear loading, geometry, and material properties of the laminate or panel. It is thus analogous to lamination theory in that ply-level stresses can be efficiently determined from global load resultants at a given location in a structure and used to evaluate the margin of safety on a ply-by-ply basis. The simplified shear solution stress distribution is zero at free surfaces, continuous at ply boundaries, and integrates to the applied shear load. The method has been incorporated within the HyperSizer® commercial structural sizing software to improve its predictive capability for designing composite structures.

The HyperSizer structural sizing software is used extensively by NASA to determine induced by the through-thickness shear load, and by imposing equilibrium both vertically and horizontally, the through-thickness shear stress distribution can be calculated. The resulting shear stresses are continuous at the ply interfaces, and are zero at the laminate-free surfaces. If both \( Q_x \) and \( Q_y \) shear loads are present, it is assumed that they act independently and that their effects can be superposed. The calculated shear stresses can be rotated within each ply to the principal material coordinates for use in a ply-level failure criterion.

The novelty of the simplified shear solution method is its simplicity and the fact that it does not require solution of a particular boundary value problem. The advantages of the innovation are that an approximation of the through-thickness shear stress distribution can be quickly determined for any solid laminate or solid laminate region within a stiffened panel.

Straight-Pore Microfilter With Efficient Regeneration

A novel, high-efficiency gas particulate filter has precise particle size screening, low pressure drop, and a simple and fast regeneration process. The regeneration process, which requires minimal material and energy consumption, can be completely automated, and the filtration performance can be restored within a very short period of time.

This filter media may not be the complete replacement for other filtration technologies, but can be a key component in a complete system. This design removes the majority of airborne particulates, with its fast regeneration time allowing a significant increase in the operating period of other filtration media (if necessary) between replacement/regeneration.

Conventional filter media are based on polymer/glass fibers, but this filter is of a novel material composite that contains the support structure and a novel coating. The support structure gives the filter good mechanical properties, while the novel coating creates a unique regeneration character. Also, this support structure can be prepared by laser micromachining etching (i.e. a chemical laser), or micro-molding technology. A novel coating shell is then formed on the support structure to further reduce the pore diameter.
